Urban District Council. A keen ambulance man, he was widely known in the West Riding as lecturer and examiner in this subject, and he was a Knight of Grace of the Order of St. John of Jerusalem in England, and an honorary life member of the St. John Ambulance Association. At the great fire and series of explosions which occurred at the Low Moor picric acid factory during the war he was conspicuous for his daring and bravery in rescue work under the most dangerous and terrifying conditions. For many years he had taken an active interest in the Epsom College Medical Foundation, of which he was local secretary, and in the work of the Boy Scouts. An esteemed member of the Congregational church, he took a large share in temperance and philanthropic work in Spenn Valley. Devoted to his profession, he rarely took a long holiday, yet his love of the sea led him to visit the shores of the Baltic, Russia, and the Canary Islands. He was a well known philatelist and authority on stamps.

Dr. Sutherland was a fine type of the old family doctor, who combined with his professional duties the part of guide, philosopher, and friend. A man of high principles and upright conduct, he had the courage of his convictions and was never afraid to express them. Withal he was one of the most lovable and kindly of men, abounding in humour, doing good by stealth, always ready to help in time of trouble. In him the poor, the needy, the suffering, and the afflicted had indeed a true friend, and the remarkable way in which the people of Cleckheaton turned out on the day of his funeral to pay a last tribute to their old friend was an index of the high esteem in which he was held by all. He will be greatly missed by a large body of friends in Yorkshire and elsewhere. He was twice married, and is survived by his widow, a son, and a daughter.

F. M. C.

We regret to record the death of Dr. F. J. TRESILIAN, at the age of 64, at his residence in Enfield, on February 14th, following a short illness. Until within ten days of his death he was actually practising, and he will be mourned by many people in Enfield and elsewhere. Born in London, Frederick James Tresilian was the second son of Stewart Stewart Tresilian, a member of a very old Cornish family who lived at Tresilian, near Falmouth. He lost his parents when very young, and was brought up by his grandmother in the old town of Cloyne, co. Cork, Ireland. From Middleton College he passed to Queen's College, Cork, where he graduated M.D., M.Ch., M.A.O. with first-class honours in 1885. He obtained the diploma M.R.C.P. Edin. in 1887, and the F.R.C.P. in 1902. He practised in Enfield from 1890 until the time of his death. He was an honorary medical officer to the Enfield War Memorial Hospital, a keen member of the British Medical Association, and of the North-East Clinical Society, of which he had been president. He was medical referee to the Prudential Assurance Company, and when he first went to Enfield was for eight years clinical assistant to the ear, nose, and throat and eye departments of the Prince of Wales's General Hospital, Tottenham, and also to the Central London Throat, Nose, and Ear Hospital. He contributed articles on nerve diseases and other subjects to the *BRITISH MEDICAL JOURNAL* and other periodicals. He leaves a widow, one son, and two daughters, one of whom is in the medical profession.

Universities and Colleges.

UNIVERSITY OF LONDON.

Chair of Physiology, tenable at University College.
Dr. G. V. Anrep has been appointed as from March 1st to the University Readership in Physiology, tenable at University College. He holds the degrees of M.D. and D.Sc.
The title of Emeritus Professor of Physiology at University College has been conferred on Dr. Herbert R. Spencer.
Sir James K. Fowler and Dr. A. Goodman Levy have been appointed Fellows of King's College and University College respectively.
Mr. H. L. Eason, M.D., M.S., was reappointed the representative of the University on the General Medical Council.

ST. THOMAS'S HOSPITAL.

Three popular lectures in physics will be given in the Governors' Hall on Tuesdays, March 9th, 23rd, and 30th at 5 p.m. The first will be delivered by Sir Richard Paget, Bt., who will speak on the nature of human speech; the second, dealing with wireless telephony with light waves, will be given by Professor A. O. Rankine, O.B.E.; and Professor C. R. Darling, F.I.C., will deliver the third on experiments with drops and globules. The lectures will be illustrated by experiments.

Professor R. H. A. Plimmer will give four lectures on vitamins in nutrition in the Governors' Hall on March 11th, 12th, 15th, and 16th at 5 p.m., illustrated by lantern slides. Admission to the lectures is free without ticket.

UNIVERSITY OF ABERDEEN.

At the meeting of the Senate on February 23rd a course of post-graduate study in medical subjects for the benefit of practitioners in the north-east of Scotland was approved. The Faculty of Medicine recommended that the course should be instituted this summer and should extend from the first week in April till the last week in June. The only fee payable will be £1 ls. registration fee.

The spring graduation ceremony was fixed for Wednesday, March 24th.

Professors Shennan and Mackenzie Stuart were appointed to represent the Senate at the Congress of Universities of the Empire to assemble in London on July 12th and to meet in Cambridge from July 13th to 16th.

UNIVERSITY OF CAMBRIDGE.

We regret that by a printer's error in the degree list published on February 20th (p. 354) the B.Chir. conferred on Mr. H. B. Stallard appeared as M.Chir.

Medico-Legal.

ACTION FOR NEGLIGENCE AGAINST MEDICAL OFFICERS.

Venn v. Todesco and Elder.

THE rehearing of the action brought by Mrs. Mary C. Venn of Thornton Heath against Dr. J. M. Todesco, resident medical superintendent of the Croydon Borough Hospital, and Dr. G. W. Elder, formerly assistant resident medical officer at the hospital, for damages for the death of her husband, which was alleged to have occurred through the negligence of the defendants, took place before Mr. Justice McCardie and a special jury, in the High Court of Justice, King's Bench Division, on February 27th and subsequent days, but the jury again disagreed and were discharged.

Mrs. Venn sued on behalf of herself, her son Laurence, and her daughter Eileen, a schoolgirl. The pleadings contained the allegations that Mr. Venn was recovering from scarlet fever and had a deep-seated abscess in the hip in March, 1922, when he was admitted into the Croydon Borough Hospital for treatment. Dr. Todesco and Dr. Elder were alleged to be negligent in not properly diagnosing the abscess while Mr. Venn was under their care. Dr. R. V. Clark, the medical superintendent of the hospital, did not examine Mr. Venn until April 24th, when he ordered an immediate operation, but, blood poisoning supervening after the operation, Mr. Venn died on June 15th. Death was alleged to be due to the "negligent delay of between six and seven weeks" at the Croydon Borough Hospital before Dr. Clark examined Mr. Venn.

The defendants pleaded that they were not negligent, and also that they were protected by the Public Authorities Protection Act, 1893.

The case first came on for hearing in June, 1925, before the Lord Chief Justice and a special jury. Dr. Clark was then entirely exonerated, but the jury disagreed as to the liability of the other two defendants. The previous proceedings were reported in the *BRITISH MEDICAL JOURNAL* of July 11th, 1925, p. 92.

Sir Henry Maddocks, K.C., and Mr. B. M. Goodman, instructed by Mr. A. S. Joseph, appeared for the plaintiff, and Mr. Neilson, K.C., and Mr. T. Cartliew, instructed by Messrs. Le Brasseur and Oakley, appeared for the defendants.

Mrs. Venn, in her evidence, said her husband never suffered from rheumatism. Cross-examined by Mr. Neilson, she said Dr. Milson, in advising her husband to go into hospital, told her that her husband had an abscess on the hip, and not merely that there was an inflammation there. She was never told that her husband had diphtheria when he went into hospital. Her husband's leg was always swollen, and the swelling did not go down from the time he entered the hospital until April 12th.

Dr. E. G. D. Milson said he treated Mr. Venn for scarlet fever in March, 1922. There were no symptoms of diphtheria then. At that time his leg had such an inflammation that it might eventually have formed pus. He did not think the inflammation on the hip could have been mistaken for a burn. If the operation had taken place ten days earlier it might have made a difference in the chance of saving the patient's life. Cross-examined by Mr. Neilson, the witness said he sent Mr. Venn into

hospital for observation regarding the inflammation and to have an operation if necessary.

Sister Smith, who was present at the operation on April 25th, 1922, said so far as she could recollect the abscess discharged nearly three pints of pus.

Laurence Venn corroborated his mother's evidence that Dr. Todesco had told them that his father was suffering from scarlet fever and rheumatism, and that it was a case of mind over matter. Each occasion they visited his father at the hospital the leg was always very inflamed. Cross-examined by Mr. Neilson, witness said although it might have been against regulations for visitors to examine patients, he and his mother on the occasion of each visit raised the bedclothes and examined his father's leg.

The Defence.

Dr. Todesco, in his evidence, said Mr. Venn was admitted on March 18th, 1922, and when he examined him on the following day there were symptoms of scarlet fever. There was some redness on the right hip, but no swelling which pitted on pressure, and he agreed with Dr. Elder, who also made an independent examination, that the redness was consistent with a burn caused by a hot-water bottle. A swab was taken of the patient's throat, and a bacteriological test revealed diphtheria. He was then transferred from the scarlet fever ward to the mixed infection ward. On March 28th he complained of pain in his leg, but an independent examination, both by himself and by Dr. Elder, revealed nothing to account for the pain other than the rheumatic condition of the patient which was common in patients suffering from scarlet fever. The witness had had cases of abscesses forming in scarlet fever, and the possibility of an abscess was present to his mind when he made his examinations. He did not suspect the presence of an abscess until April 24th, when he telephoned to Dr. Clark, who then examined the patient, and ordered his removal to the general hospital for an immediate operation. At no time did he hear that Dr. Milsom had sent the deceased into the hospital for observation regarding the inflammation of the leg. Cross-examined by Sir H. Maddocks, witness said some abscesses were difficult to diagnose on account of their depth. An abscess beneath the muscles, especially a thick muscle like the thigh, might give no indication of its presence except pain, and that he attributed to rheumatism. He did not think a previous history of the case would have helped him. He did not think that if the operation had been performed on April 13th, instead of April 26th, it would have made any difference.

Dr. Elder said he examined Mr. Venn in the ambulance before admission. He then only suspected scarlet fever, and ordered the patient to be placed in the scarlet fever ward, but upon a swab being taken of the patient's throat which revealed diphtheria he ordered him to be removed to the mixed infection ward. In his opinion there was nothing to do except to watch the patient. Mr. Venn himself told witness he had been a martyr to rheumatism, and also that the redness on his leg was a burn caused by the application of a hot-water bottle. He did not ask Mrs. Venn about Dr. Milsom's diagnosis and she did not tell him. Cross-examined by Sir H. Maddocks, witness said both he and Dr. Todesco made independent entries on the admission card. He did not diagnose the deep-seated inflammation until April 25th.

Dr. Veitch Clark said Dr. Todesco and Dr. Elder worked under him at the Isolation Hospital in 1922. Witness visited the hospital two or three times a week, being the administrative officer of the whole department. He had found both doctors trustworthy and conscientious, Dr. Todesco being known to him for eight years and Dr. Elder for three years. Witness saw Mr. Venn in the hospital twice—once in the first week in April, 1922, and again on April 25th, when he was rung up for a consultation. On that day he detected a deep-seated abscess in the right thigh, and so he called in Mr. Adams, the surgeon, who operated. The chart was not consistent with deep-seated inflammation or abscess when the patient was admitted. That was absolutely negatived by his temperature. In his opinion, Mr. Venn could not have had the abscess down to April 10th, for he himself examined Mr. Venn carefully just before that date and there was no inflammation at all in the leg. He knew of no disease in which an abscess formed more rapidly than in a case of scarlet fever. Cross-examined by Sir H. Maddocks, witness said that with deep-seated inflammation an abscess was likely to form in a day or two.

Dr. G. E. Newby, honorary surgeon to the Croydon General Hospital, said that from what he had heard of the evidence he did not think that there had been any negligence whatever.

At this stage of the hearing the jury intimated that a majority of their number had come to a decision, but Sir H. Maddocks, for the plaintiff, said he would not agree to accept it, and the case therefore continued.

Dr. William Hunter, consulting physician to the London Fever Hospital and Charing Cross Hospital, said he had made a careful study of the documents connected with the case, and he had come to the conclusion that it was absolutely impossible for Mr. Venn to have had a condition of pus in his body when he was admitted to the hospital. In the circumstances the doctors could have done nothing but watch Mr. Venn's case with care. For a patient to complain of pain in the hips and joints was usually indicative of rheumatism, which was the most common complication of scarlet fever. The case was a very difficult one, and nothing could have been done until—as in this case—the operation was performed.

The Summing-up.

Mr. Justice McCardie, in his summing-up, said although the case was of importance to the plaintiff, it was also important to

the defendants, because every professional man, certainly every man engaged in the medical profession, valued his reputation and his honour, and unless the case was clearly proved against him he was entitled to say: "You ought not to find against me." The law on the matter was, in his opinion, free from doubt. Many phrases had been referred to to indicate the measure of duty which rested upon a doctor—a duty which existed whether the doctor were paid by the patient or whether the patient were treated, as Mr. Venn was treated, at a public institution. To his lordship's mind, the duty could be stated in words that did not admit of further definition or further amplification. The words were these: that a doctor must show to his patient, and exert towards the patient, reasonable skill and reasonable care. In the medical profession, as in other professions, there were men of different gifts; for example, in surgery there was the man who possessed singular powers of insight, great operative capacity, and who gained a world-wide reputation. There was, on the other hand, the man who possessed ordinary gifts, ordinary skill, and the ordinary capacity for care. That was the standard that must be applied. In this case (continued his lordship) one noticed, to begin with, that the defendants were both men of excellent qualifications. Sometimes one found that a doctor was engaged in the treatment of a case or a trouble of which he had had but little experience, but in this case, as they knew, Dr. Todesco for a good many years, and Dr. Elder for a considerable period of time, had gained a wide and accurate experience of scarlet fever cases, and they were engaged in this infectious hospital as the resident medical officer and the assistant medical officer respectively. What was the case alleged against them by way of negligence. Not that they themselves did not operate, because they were not surgeons. It was important to remember that the case alleged against them was that they failed in diagnosis; in other words, that they diagnosed too late the existence of an abscess in Mr. Venn. That led up to this point for the jury to remember, that of all the functions a medical man had to fulfil there was none more difficult and more delicate than diagnosis. Upon many subjects of life opinions differed, but the human body was the most difficult thing in respect of which a doctor had to say that there was specific trouble, or a specific internal complaint, and the case against the defendants was that they were guilty of want of reasonable skill and want of reasonable care in regard to this most difficult subject of diagnosis. A diagnosis in respect to what? Not to some external and immediately observable feature in the human body, but a diagnosis in respect to a deep-seated abscess, and the whole of the evidence pointed to this: that, difficult though diagnosis was with respect to many matters, there was no matter with respect to which it was so difficult as with regard to a deep-seated abscess. There were two matters which his lordship himself felt he should like to consider, and they were these. It was often said that a doctor had differed from another doctor. So he had, because the human body lent itself to many differences of opinion, but it was not negligence for one doctor, competent and careful, to form one opinion, and for another man as competent and careful to form another opinion. In fact, in his view it was the duty of a medical man, just as it was the duty of a lawyer, or any other professional person, to form his opinion honestly and to the best of his ability, and, having formed his opinion, to express it. The professional man who failed in that failed, in his lordship's view, in his duty as much as a judge who, having formed an opinion of the case, lacked the courage to express it.

His lordship then exhaustively reviewed the facts of the case as given in evidence, but pointed out that in this case they had many documents showing details of the patient from day to day—the chart of temperature, the nurses' reports, etc. When he took those documents he asked himself: When Mr. Venn was sent to the hospital as an ordinary patient to take his place with 170 to 200 people there, what conceivable interest was there on the part of Dr. Todesco, or Dr. Elder, or the nurse, or the clerk, and what conceivable motive was there, to put down anything that was not true? They would realize the doctors' attitude in this matter, and they would know that one of the proud things of a hospital was to turn out the patient cured. That was the pride of the hospital—professional pride. If they went round the hospitals they would see that the nurses looked upon the patient, not as a mere patient, but as a case so that she afterwards could say: "He came in ill and he went out well." These records were made when no one had any conception that any action would arise out of the case. It was the right of a judge, in trying a case with a jury, to express an opinion he had formed, subject to their judgement as a jury upon the evidence. This was the second of two very prolonged trials, and, exercising his right, remembering that they were the judges of fact to take an opposite view if they thought it proper to do so, he himself had formed the conclusion that upon the evidence before the court these defendants ought not to be found guilty of negligence. He further felt, if one weighed the documents and the whole of the testimony in the case, that if a doctor were to be found guilty of negligence upon such testimony as that before them, then no doctor would be safe. He knew from what happened on Friday that the overwhelming majority of the jury were in favour of the defendants, but the one jurymen who took an opposite view would, his lordship hoped, reflect that cases of this sort were not, and ought not, as a matter of duty to be determined on mere sympathy. Every judge must remember that it was his duty to decide not on sympathy but upon testimony, because unless he decided upon testimony he failed in his duty.

The jury retired for an hour, but, being unable to give a unanimous verdict, they were discharged.

The question of law whether the defendants were protected by the Public Authorities Protection Act, 1893, was reserved for argument on a future date.

The Services.

FOREIGN DECORATIONS.

The following decorations have been conferred by the President of the French Republic in recognition of services during the course of the war, 1914-19:

Médaille de la Colonel William General Gerald C. Henry Herriek, C.B. C.M.G., T.D., T.F., Charles P. Templeton, C.B.E., D.S.O., C.A.M.C., Albert G. Thompson, C.M.G., D.S.O., retired pay, late R.A.M.C., Hugh S. Thurston, C.B., C.M.G., C.B.E., retired pay, late R.A.M.C.; Lieut- Colonels Harold Collinson, C.B., C.M.G., D.S.O., T.D., R.A.M.C.(T.F.), Pierre Z. Rheume, C.A.M.C., Eugene Ryan, C.M.G., D.S.O., R.A.M.C.; Majors Henry D'A. Blumberg, O.B.E., T.D., R.A.M.C.(T.F.), John M. M. Crawford, O.B.E., R.A.M.C., Joseph A. Luesier, C.A.M.C., Michael J. Mahony, D.S.O., T.D., R.A.M.C.(T.F.), Arthur J. Mollison, R.A.M.C., George S. Parkinson, D.S.O., R.A.M.C., Alfred N. Rivet, C.A.M.C., Edouard C. Saint-Pierre, C.A.M.C., George H. Stevenson, O.B.E., M.C., R.A.V.C.(S.R.), Alan C. Turner, D.S.O., T.D., R.A.M.C.(T.F.); Captains Alfred J. Clark, M.C., C.A.M.C., James Jackson, R.A.M.C.(T.F.), Louis de G. Joubert, C.A.M.C., Joseph A. Lorrain, C.A.M.C., Ernest S. Stork, D.S.O., R.A.M.C.(T.F.), Ernest W. Strangé, R.A.M.C.(T.F.); Temporary Captains William H. Rayner, R.A.M.C., David L. Williams, M.C., R.A.M.C. En Bronze: Majors Harold E. Griffith, T.D., R.A.M.C. (T.F.), Harry C. Sidgwick, Captains Ernest A.M.C., Eric M. Jardine, O.B.E., O.B.E., B. Pike Townse R.A.M.C.	En Fermeil: Brevet Lieut- S.R.). En Argent: Major- pay, late A.M.S.; Colonels Alexander D. Sharp, C.B., C.M.G., T.D., T.F., Charles P. Templeton, C.B.E., D.S.O., C.A.M.C., Albert G. Thompson, C.M.G., D.S.O., retired pay, late R.A.M.C., Hugh S. Thurston, C.B., C.M.G., C.B.E., retired pay, late R.A.M.C.; Lieut- Colonels Harold Collinson, C.B., C.M.G., D.S.O., T.D., R.A.M.C.(T.F.), Pierre Z. Rheume, C.A.M.C., Eugene Ryan, C.M.G., D.S.O., R.A.M.C.; Majors Henry D'A. Blumberg, O.B.E., T.D., R.A.M.C.(T.F.), John M. M. Crawford, O.B.E., R.A.M.C., Joseph A. Luesier, C.A.M.C., Michael J. Mahony, D.S.O., T.D., R.A.M.C.(T.F.), Arthur J. Mollison, R.A.M.C., George S. Parkinson, D.S.O., R.A.M.C., Alfred N. Rivet, C.A.M.C., Edouard C. Saint-Pierre, C.A.M.C., George H. Stevenson, O.B.E., M.C., R.A.V.C.(S.R.), Alan C. Turner, D.S.O., T.D., R.A.M.C.(T.F.); Captains Alfred J. Clark, M.C., C.A.M.C., James Jackson, R.A.M.C.(T.F.), Louis de G. ---	--

Medical News.

The Fellowship of Medicine announces that on March 11th, at 11, Chaudes Street, Colonel F. E. Fremantle will deliver a lecture on the economics of public health at 5 p.m.; this lecture is open to all members of the medical profession. On the same day, at 5 p.m., Mr. E. T. C. Milligan will give a special demonstration in clinical surgery at St. Mark's Hospital, free to members of the Fellowship and to ticket-holders of its general course. A three weeks' course in gynaecology at the Chelsea Hospital for Women will begin on March 8th and last for three weeks. The daily afternoon demonstrations on the diagnosis and treatment of diseases of the eye continue throughout the week at the Royal Eye Hospital, beginning at 3 p.m. From March 15th to 26th the Hampstead General Hospital will hold a daily course for general practitioners from 4.30 to 6 p.m., including surgical and medical demonstrations and lectures. The London School of Tropical Medicine begins a series of eight clinical demonstrations on March 16th, and will continue for four consecutive weeks on Tuesdays and Thursdays at 2 p.m. Copies of all syllabuses and of the general course programme may be had from the Secretary of the Fellowship of Medicine, 1, Wimpole Street, W.1.

At a joint meeting of the Education and Medical Sections of the British Psychological Society to be held at the house of the Royal Society of Medicine, 1, Wimpole Street, W.1, on Monday, March 8th, at 8 p.m., a discussion on the definition and diagnosis of moral imbecility will be opened by Drs. Cyril Burt, M. Hamblin Smith, W. Rees Thomas, F. C. Shrubbsall, and A. F. Tredgold. The chair will be taken by Dr. R. H. Cole.

At the meeting of the Zoological Society of London on Tuesday, March 9th, at 5.30 p.m., Mr. F. P. Stowell will make a communication on the purification of sea water by storage. Dr. Francis (Baron Nopcea) on heredity and evolution, and Dr. W. C. Osman Hill on a comparative study of the pancreas.

A SESSIONAL meeting of the Royal Sanitary Institute will be held on March 12th and 13th in the Town Hall, Hastings. Discussions will be held on "Mothercraft and fathercraft," and on the effect of the Public Health Act of 1925 on the work of municipal engineers and sanitary inspectors, under the chairmanship of Professor H. R. Kenwood. On March 26th a sessional meeting will be held in the Guildhall, Derby, when discussions on goitre and on some aspects of the housing problem will be held under the chairmanship of Dr. G. F. Buchan.

THE annual general meeting of the National Baby Week Council was held on March 4th, under the chairmanship of Dr. Mary Scharlieb, vice-president of the council. Addresses were given by Dr. J. R. Kaye, county medical officer for the West Riding, on the economics of maternity and child welfare, and by the Hon. Mrs. Bernard James on the rural child. The Astor silver challenge shield for the most effective local baby week campaign in 1925 was won by Northampton, and Astor banners by Littlehampton and Arundel, and Wigan Health and Baby Week Committees. Certificates of merit for baby week campaigns were awarded to six other districts.

At a meeting of the Pharmaceutical Society of Great Britain to be held at 17, Bloomsbury Square, W.C.1, on Tuesday, March 9th, at 8 p.m., a paper on British pharmacy and its relation to Continental practice will be read by Mr. Edmund White, B.Sc., past-president of the Society, to be followed by a discussion. Medical friends of members will be welcomed.

THE Council of Epsom College will shortly award a St. Anne's Home Scholarship of the value of £48 a year. Candidates must be between the ages of 7 and 12, and must be the orphan daughters of duly qualified medical men who have been for not less than five years in independent practice in England or Wales. Particulars can be obtained from the Secretary, at the office of the College, 49, Bedford Square, W.C.1.

AN exhibition of artificial sunlight (ultra-violet radiation) lamps and other electrotherapeutic appliances will be held in two of the evacuated wards of the west wing of the Middlesex Hospital between 11 a.m. and 6 p.m. daily from March 11th to 16th. The exhibition will be open, on presentation of visiting card, to all members of the medical profession, to members of public health committees, and to others directly interested in the working and application of the apparatus. The general public will not be admitted. There will be no charge for admission. The exhibition will be open also on the evening of March 10th, when the research laboratories of the Middlesex Hospital will be open for the inspection of invited guests.

A HOLIDAY course in children's diseases will be held from April 7th to 17th, at the Hôpital des Enfants Malades, 149, Rue de Sévres, Paris. The course will be of a comprehensive character, and include radiological examination, heliotherapy, and diagnosis and treatment in general. The fee for the course is 150 francs, and further information may be obtained from the secretary at the hospital.

A "DR. RUSSELL BED," dedicated to perpetuate the memory of the close friendship between Mr. Philip Jeffery Walker and the late Dr. James W. Russell, was formally accepted by the Lord Mayor of Birmingham on behalf of the General Hospital, Birmingham, on February 26th. The bed was endowed by Mrs. E. E. Walker, Mrs. Sydney Evershed, and Mr. T. Sydney Walker. On the same occasion a bed endowed by the Birmingham University students from the proceeds of the carnival last year was also accepted.

ON the occasion of his retirement, after fifty-two years' service as medical officer of health to the Tipton Urban District, Dr. A. S. Underhill has been presented with a cheque, publicly subscribed, for £327.

THE tenth international congress for the protection of infancy and maternity will be held at Madrid in the spring under the patronage of Alfonso XIII, with Dr. Martinéz Vargas as president. The following subjects, among others, will be discussed: (1) The influence of summer heat on the infant, (2) isolation of institutions intended for infants, (3) prophylaxis of infantile ailments, (4) prophylaxis of infections in infancy, and (5) protection of the mother during pregnancy.

THE fifty-third annual issue of *Willing's Press Guide*, described in the subtitle as the Advertisers' Directory and Handbook, has now been published. This yearbook provides an index to the periodicals of Great Britain and Ireland, a list of telegraphic news and reporting agencies, and of the principal colonial and foreign journals. It is published by James Willing, Ltd., at 2s. 6d.

Health and Empire, a new quarterly review, is to be published by the British Social Hygiene Council this month. It will deal with social hygiene generally, and the contributors to the first issue include Professors Cyril Burt, Leonard Findlay, Percy Nunn, and Dr. C. J. Bond.

THE Académie de Médecine of Paris has awarded the Prince Albert of Monaco prize of 100,000 francs to Professors Hédon of Montpellier and Laguesse of Lille for their respective works on the internal secretion of the pancreas and the organization of scientific work.

IN connexion with the annual Hospital, Health, Nursing, and Midwifery Conference and Exhibition to be held at the Central Hall, Westminster, from April 12th to 16th, one section will deal exclusively with health work performed by voluntary associations in the United Kingdom. Among the bodies which have already agreed to co-operate are the Central Council for Infant and Child Welfare, the Mothercraft Training Society, the British Red Cross Society, and the National Institute of Public Health.

THE first urological congress of the Union of Soviet Republics will be held at Moscow in the spring, when the following subjects will be discussed: tuberculosis of the genito-urinary tract, introduced by Professors S. P. Fedoroff and Kholzoff; and chronic gonorrhoeal infection, by Dr. Zaigracff, Professor Lejueff, and Dr. Finkelstein.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the **BRITISH MEDICAL JOURNAL** alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the **BRITISH MEDICAL JOURNAL** must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the **JOURNAL**, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the **BRITISH MEDICAL JOURNAL** are **MUSEUM 9861, 9862, 9863, and 9864** (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are:

EDITOR of the **BRITISH MEDICAL JOURNAL**, *Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Mediscera Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 4737 Dublin), and of the Scottish Office, 6, Drumshugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 4361 Central).

LETTERS, NOTES, ETC.

INDIVIDUAL OVERDOSE OF ULTRA-VIOLET RAYS.

DR. JOHN H. TONKING (Camborne) writes: An instance of possible injurious effects of ultra-violet rays came under my observation lately. A young woman was admitted to a nursing home for miscarriage at the fifth month under my care. During convalescence she informed me that she had been receiving "double doses" by a violet-ray "specialist" with a view to endowing her future offspring with great vitality.

HERPES AND VARICELLA.

DR. E. A. SEYMOUR (Hampstead, N.W.3) writes:—In view of the recent correspondence as to the connexion between herpes and varicella, the following case is perhaps worth recording: On January 24th Mrs. X, aged 42, developed herpes of the frontal nerve. The attack was severe, and the vesicles, which were large, had all appeared by January 26th. The temperature kept about 99° F. On January 31st it rose to 102° and a typical varicella eruption appeared. In neither case could any source of infection be traced.

AN ODD CAUSE OF DIARRHOEA.

DR. C. J. HILL AITKEN (Kilnhurst, near Rotherham) writes: A little girl of 3 had relaxed motions for some weeks. She looked in the best of health, and I wondered if possibly this looseness was natural to her. The mother gave a history of two masses of threadworms having been passed some time back, but only very occasionally now did she see even one worm. She volunteered the statement that the motions were such as one would expect after the taking of opening medicine. I elicited the presence of marked tenesmus on one occasion, without the passage of any motion. I noticed that the ends of the child's fingers were brown-stained, and drew the mother's attention to it. "That," said the mother, "is aloes, which, since she passed the worms, I smear on twice a day to prevent her sucking her fingers when she goes to bed. It is difficult to wash off." I substituted a quinine lotion for the aloes sticky mass, and in two days the motion was formed and remained so.

OCCUPATIONAL BURSA.

DR. J. FANNING (London, E.) writes with reference to the description by Mr. McAdam Eccles of "dustman's bursa" (*JOURNAL*, February 20th, p. 323) to report another form of occupational bursa which he has encountered recently. A painful swelling in the neighbourhood of the right knee developed in a bank clerk, and a distended and inflamed bursa over the ligamentum patellae was found to be present. The explanation appeared to be that the clerk in the course of his work had frequently to open and close drawers, and it had become a habit with him to close them with his knee.

A CRIMEAN VETERAN.

When we stated, in the obituary notice of the late Dr. A. C. W. Norton (*BRITISH MEDICAL JOURNAL*, February 20th, p. 354), that he "must surely have been the last surviving medical veteran of the Crimea," we were in error. We are informed that there is at least one such still living—Dr. James Duncan MacLaren, formerly of Glasgow, but now living in retirement at Elie in Fife. Dr. MacLaren took the M.D. Glasg. and the L.R.C.S. Ed. in

1854, and served during the Crimean war as assistant physician in the civil hospital at Renkiof in the Dardanelles. He subsequently became F.R.F.P.S. Glasg. in 1866, and was for many years physician to the Royal Infirmary and to the Western Public Dispensary in Glasgow, but has long since retired from practice. It is possible that there may be others still alive; the deaths of retired soldiers who served in the Crimea are still, from time to time, reported in the press.

INTRAVENOUS INJECTIONS OF TARTAR EMETIC IN BILHARZIASIS.

DR. F. G. CAWSTON, who writes from Durban (a city, he says, on the banks of three rivers known to be heavily infested with the bilharzia parasite), sends some observations on the treatment of bilharziasis. I have shown (he writes) that, unless very large doses of emetine are employed, it is essential to continue the treatment uninterruptedly for at least twenty-four days, but that the cardiac depression that so often occurs during the third or fourth week of the injections renders emetine a risky drug to use. Rectal injections of tartar emetic are far from satisfactory, because it is impossible to estimate the amount of the drug that will be absorbed through the bowel wall. A patient of 12 noticed the taste in his mouth a quarter of an hour after I had injected 8 grains into the bowel, but he showed no other symptoms; the previous day he had received a rectal injection of 4 grains. A native of 13 received 8 grains on the first day, 12 grains on the second, and 16 on the third day. On each occasion the solution was left in the bowel when he returned home, after lying down for half an hour. There were no toxic effects, except that the patient noted a taste in his throat about a quarter of an hour after each injection. The possibility of curing a patient by one dose of tartar emetic is very remote, and the risk of killing a large number of blood parasites in a short time and rendering them liable to be carried about in the blood stream is too great to warrant the use of heroic methods for this condition. Provided one is on the look-out for kidney-albumin in the urine towards the close of treatment with tartar emetic, and confines oneself to the use of a freshly prepared solution in a limited amount of saline, a course of intravenous injections, skilfully administered over a period of one month, may be regarded as non-toxic and as the method of choice for all cases where a suitable vein can be found.

INFANT WELFARE IN THE MALAY STATES.

The Infant Welfare Centre in Kuala Lumpur, Federated Malay States, which was opened in 1922, continues to flourish, as judged by the report for 1924 recently issued. Its staff now consists of one whole-time medical officer (Dr. M. Josephine Were), two European nursing sisters, and four health visitors. Certain curious superstitions have had to be overcome, such as that which for a time threatened to stop any regular weighing of the babies, but this is gradually being eliminated by means of posters and lectures to the Chinese, Tamil, and Malay mothers. Antenatal work is also well established, and a striking example of the value of this work is shown by the case of a woman who had had three stillborn babies and was found to be infected with syphilis. This was so effectively treated that the next baby was not only healthy but won first prize at a baby show some months later. This baby competition—held in July, 1924—was the first of its kind in the Federated Malay States, and, once the superstitions of the mothers had again been overcome, proved very successful, over 240 entries being received.

HEALTH OF THE MAORIS.

The general health conditions in New Zealand are sufficiently *ide* which that country takes in them. *ct* test when the health of the native *but* in this case it emerges from a close *sor*intiny with complete satisfaction. The Health Department of New Zealand has a division of Maori hygiene, which came into existence at the beginning of this century, and had for its first medical officer of health the first Maori graduate in medicine, Dr. Pomare, *ioneer* work in instituting *public* opinion on health *matters.* *Ce* *re* appointed some years *later* to do health work as Maori sanitary inspectors, and in 1903 another Maori medical officer of health was appointed, Dr. To Rangī Hīroa, who is now, after serving in the war, Director of the Division of Maori Hygiene. The native school teachers have been successfully encouraged to take an interest in the health of the school child, and medical examinations of the native school children date back to 1908. There are now over twenty native health nurses, who have been of the greatest service in coping with epidemics in the populous Maori districts and by their lecturing to the womenfolk they have become an important *educative* factor. Various pamphlets in the native language on the feeding of babies, typhoid, influenza, tuberculosis, etc., are distributed to the native population.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 45, 46, 47, 50, and 51 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 48 and 49.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 87.

EXCRETION OF ALCOHOL IN THE URINE AS A GUIDE TO ALCOHOLIC INTOXICATION.

BY

H. W. SOUTHGATE, M.B., B.Sc.LOND.,
LECTURER IN PHARMACOLOGY, SHEFFIELD UNIVERSITY;

AND

GODFREY CARTER, M.B.Vict., M.R.C.P.Ed.,
D.P.H.LOND.,

LECTURER ON FORENSIC MEDICINE, SHEFFIELD UNIVERSITY; SENIOR
POLICE SURGEON, SHEFFIELD.

(From the Pharmacology Department, Sheffield University.)

INTRODUCTORY NOTE.

BY

GODFREY CARTER.

WITHIN the range of forensic medicine there is no subject upon which medical evidence is more unsatisfactory than that appertaining to drunkenness. It is difficult to reduce a varying group of symptoms and appearances to a formula which can be stated; still more so to a definition which will convince a lay bench of magistrates that the symptoms described are really due to alcoholic consumption, and may not, individually and collectively, be ascribed to other causes; and yet the recognition of indulgence in alcohol presents few difficulties at the time. Every member of a social group can say with accuracy when a member of that group ceases to be normal and gives definite indications that sobriety has passed into insobriety. The picture is made up of many changes, subtle yet recognizable, in speech, appearance, manner, and conduct. It is something we can sense, but analyse and subsequently describe with difficulty.

When for legal purposes it comes to applying a number of tests—such as standing poised, toeing the line, standing immobile with closed eyes, repeating certain words or phrases, smelling the breath, and testing the memory of lapse of time, etc.—the results are very unsatisfactory. We have recently had experience of nerve specialists disagreeing with practitioners in court on the question of drunkenness, and all agreeing that our tests are inadequate and inconclusive.

No two men behave exactly alike under the influence of alcohol, or present the same combination of objective symptoms. The result is that many cases of accusation in the courts on the charge of drunkenness, where serious motor accidents have occurred, are wrongly dismissed for want of evidence which would be unanimously convincing to the bench.

I am sure that too much is made of one sign. It is almost the rule for the constable in charge to open his evidence by saying, "The accused smelt strongly of drink." Certainly my examination in many cases fails to confirm this. It is possible that it may be due to lapse of time since apprehension, but I think not. Does the smell of a man's breath, as regards alcohol, increase *pari passu* with the number of glasses of stimulant he has swallowed? I think not. At most the smell of the breath indicates that some alcohol has been consumed. Therefore I do not think the test is of much positive value; it is of importance in a negative sense. There are five signs to be observed in making an examination which influence me considerably, taken in association with the other symptoms. They are: (1) flushed face; (2) sweating; (3) dilated pupils; (4) congested eyes; (5) rapid pulse; and they are present in nearly all instances.

What we, and the courts, have to decide is, as Dr. Frederick Smith puts it in Taylor's *Medical Jurisprudence*: "Was the person's mental condition, which led to the proceedings, and caused him to behave in the manner he did, prior to his arrest, produced by alcohol? If so, he was drunk within the meaning of the proceedings."

In the majority of cases the police surgeon hears nothing of the charges of being drunk and disorderly which are considered every morning in the courts of our towns and cities, but of late years a more serious class of offence has

come into prominence in which the issues are of great moment morally and materially. I refer to charges of being drunk whilst in charge of motor cars. These offences are most frequently laid against people of some social standing. Serious or perhaps fatal injuries have been inflicted, as well as much damage done to vehicular property. Those charged realize the extreme importance to themselves of establishing their innocence under such serious accusations, and almost invariably make indignant denial. After the police surgeon has examined them they often demand the presence of their own medical advisers. Valuable time has been lost, even before the first doctor arrives at the charge office; more before the advent of the second. And this time factor is of great importance. All who have had experience of the class of case I am considering will agree that nothing sobers a man more quickly after a vehicular accident than finding himself in a police lock-up with the certainty of court proceedings in the morning. I am often impressed with this power of regained control, judging by a person's demeanour and behaviour in an hour's time, as compared with his proved state of instability when arrested and a knowledge of the things he has said and done. He will often go through the usual ambulatory, static, and oral tests with flying colours, so to speak, or fail in only one. Also he will take care to assert that any deviation from the normal which he may present is entirely due to the shock of a collision, with the added anger of the accusation made against him. Then comes further lapse of time, with its sobering effects, before the second medical examination is made. Afterwards in court the defending solicitor urges, in tones of indignant protest, that the cardinal signs of quick pulse, flushed face, and dilated pupils are but the result of an innocent man having been shaken by an accident, wrongly arrested, and charged afterwards with drunken conduct. If it be alleged that his breath smelt of alcohol he will probably state that he had partaken of a glass of liquor but was certainly not drunk.

I learnt from Professor E. Mellanby that Dr. Southgate,¹ who had done much work on the relation of alcohol in the blood and urine, was anxious to carry out an investigation to see if a knowledge of the concentration of alcohol in the urine was of any medico-legal value in the detection of drunkenness, but that for such work my collaboration was necessary. He suggested that it might be possible to state approximately the quantity of alcohol any person charged with drunkenness might have drunk, and that a study of the subject might lead to the determination of a figure representing the alcohol in the urine which would indicate a condition of definite intoxication of the individual, and certainly an unfitness to drive any vehicle on a thoroughfare with safety to himself and the public. Dr. Southgate was able to promise that, if I would procure specimens of urine from persons so charged, and give the time since the arrest, he would carry out the quantitative analyses and furnish me with the reports in an hour's time—that is, in time for the police-court proceedings. It seemed to me that the prospects of developing a simple test which could at least provide definite information that alcohol had been consumed was worth following up, and I gladly gave my assistance. In no work on forensic medicine could I find any reference to the estimation of alcohol in the urine, and it seemed to me probable that the development of the idea might be of service to this branch of medicine. It was at least clear that, in view of an examination of this kind, it would be of no use for a charged person to allege, as does happen, that he has not had any alcoholic beverage or only a small libation, for when alcohol is found in any quantity in the urine it has surely gone in at the mouth.

I arranged that a record should be kept, and an entry made in the police books, of the condition and appearance of persons when apprehended on the charge of drunkenness, and that specimens of urine should be obtained and sent to Dr. Southgate for analysis, so that it would be possible to compare the symptoms of intoxication as observed at the police station with the figures representing the alcoholic concentration in the urine. I obtained permission for a general order to be sent out to all stations within the city boundary that a sample of urine should be obtained in cases of this character as soon as possible after arrest.

A supply of blank labelled bottles was distributed with instructions for urines collected to be dispatched at once to the university, and I emphasized the necessity of quick bottling to prevent alcoholic evaporation. It was our desire to obtain if possible fifty samples before giving our results, but unforeseen obstacles were encountered. The number of specimens sent was so small that I instituted an inquiry into why instructions were not being carried out. Then a fact was brought to my notice, which I was soon able to verify—namely, that if there be one thing a drunken man will not do it is to empty his bladder when requested. He will make every excuse and tell you any manner of fairy tales, but he will not micturate to order, even with a distended bladder. I think he becomes suspicious. Stratagem was then my only resource. So we have set apart a particular cell for "drunks" at the central police station. The lavatory is boarded over loosely for a while. On one side wall a urinal has been affixed, the discharge pipe from which passes directly through to another cell and empties over a receptacle placed beneath it. Nothing is said to the suspect, no request is made, and we find that, in the seclusion of his temporary abode, Nature asserts itself, and we get our sample without difficulty or delay. On the bottle is placed the number from the charge book register, the time of arrest, and the hour when the urine was passed.

In cases of gross intoxication the condition is obvious, and hardly requires a medical man's examination, but still, even these cases are sometimes keenly contested. I think the great value of the urine tests will be in borderland cases, where alcohol has obviously been consumed, but in unascertained quantity, where the symptoms of intoxication are of moderate degree, and where it is alleged for the defence that so little alcohol has been consumed that the conduct complained of could not be attributed to that cause.

EXPERIMENTAL WORK.

BY

H. W. SOUTHGATE.

The idea of correlating the toxic effects produced by alcohol with the corresponding concentration of that compound in the urine is not new. Widmark² (1915) reported the results of examining the urines of 27 individuals arrested for alcoholic intoxication. The results varied from 450 to below 200 mg. of alcohol per 100 c.cm. of urine. Results with acetone were reported by him in 1919. Miles³ (1924) gave interesting comparisons of the toxic effects produced, with a corresponding alcohol urine concentration over a period of two hours, when a dilute solution of alcohol was given to six comparable subjects. During the last two years a study of the experimental data I had obtained of blood and urinary alcohol content in the case of three men convinced me that practical use could be made of the relationship between urine alcohol concentration and the corresponding toxic effect produced in the human subject. Miles had only worked with small doses of alcohol, the action of which could not be detected except by testing with instruments of precision, but the ratio results he obtained I have been able to confirm with much larger doses of alcohol, and extending over a much longer period.

In the light of results I had obtained in the case of my experimental subjects, whose consumption of alcohol was known, I thought it would be interesting to examine the alcoholic content of the urines of those arrested for intoxication. Before giving these data, and the symptoms of intoxication exhibited by the subjects when charged at the police station, I shall first state the experimental evidence upon which this method of examination is based. It will be more possible then to see in what ways the method can be developed by further work, what it is capable of indicating, and what are its limitations. I shall supply evidence on three points:

(1) The alcohol in the blood is related to the amount of alcohol consumed when this is imbibed under constant conditions.

(2) The relation of alcohol in the blood to alcohol in the urine is a fairly constant one in many circumstances.

(3) The concentration of alcohol in the blood is related to symptoms of intoxication of the central nervous system.

If these propositions can be established it is clear that the concentration of alcohol in the urine is also related to alcoholic intoxication. I shall describe and discuss the police court results in the light of the experimental data.

1. Alcohol in the Blood.

It is important to realize that the behaviour of alcohol in the blood is different from other substances eaten as foodstuffs. Most foods after digestion and absorption from the alimentary canal are either stored or oxidized by the body fairly rapidly, so that soon the blood shows no distinctive signs of their presence. This can be seen to happen to glucose, the end-product of carbohydrate digestion, in Fig. 1. After taking 75 grams of glucose

FIG. 1.—Difference between blood alcohol curve and blood sugar curve.

the amount of this substance had sunk to normal in one and a half hours. After drinking a solution containing 75 grams of alcohol it can be seen that even six and a half hours later the blood of a man contains a good deal of this substance—namely, 75 mg. per 100 grams of blood—and from the rate of disappearance, as evident on the curve, it would be present in recognizable amounts even twelve hours after the time of drinking. Thus, although the maximum concentration of glucose and alcohol in the blood after these have been taken by mouth is reached about the same time, glucose disappears quickly and the alcohol disappears slowly. The straight line indicating the rate of disappearance of alcohol from the blood is no mere coincidence. E. Mellanby⁴ was the first to show on dogs that after alcohol has reached its maximum concentration it disappears at a uniform rate from the blood. He showed the further remarkable result that the rate of disappearance of alcohol is independent of the concentration. Thus, in the case of a dog, increasing the amount of alcohol by mouth brings about a corresponding increase in the alcoholic concentration in the blood. This animal was given on different occasions a 20 per cent. solution of alcohol by mouth, containing respectively 55, 50, 30, and 20 c.cm. of absolute alcohol. In each case the alcohol was given when the stomach was empty. The points of maximum concentration of alcohol in the blood on the different occasions are 372, 357, 212, and 120 mg. per 100 grams of blood; these figures do not differ greatly from the ratios of the amounts of alcohol drunk—namely, 2.75:2.5:1.5:1.

Having now seen that there is a relationship between the alcohol consumed and the alcohol in the blood, when the alcohol is taken by the same individual under the same conditions, it is necessary to see whether there are conditions which tend to depress the alcohol concentration; for these same conditions will probably depress also the symptoms of intoxication if these two are related. Some of these will now be briefly mentioned.

(a) *Dilution*.—If two solutions, say of 5 and 20 per cent. strength, containing equal quantities of alcohol are drunk by the same individual under the same conditions, the

	W. N.	126	155	88	226	123	1.46	1.45	2,376

alcohol concentration will rise more rapidly and to a higher point in the case of the stronger solution, as Mellanby showed. In Fig. 2 will be seen the blood concentration curves of J. H. B. after 1,920 c.cm. of beer containing 5 per cent. alcohol, 1,200 c.cm. 8 per cent. aqueous alcohol, and after 235 c.cm. of whisky diluted with an equal volume of soda water, thus forming a 20 per cent. solution. In each of these three cases the equivalent of 96 c.cm. of absolute alcohol was taken on an empty stomach. The time of drinking was about the same in each case. It will be seen how the maximum concentration

FIG. 2.—J. H. B. fasting.

risers with increasing concentration of the alcohol drunk. Therefore the more dilute the solution, the less will be the concentration of alcohol in the blood.

(b) *Rate of Drinking.*—Diminishing the rate of drinking alcoholic beverages will delay the accumulation of alcohol in the blood. The effect on the maximum point of concentration of alcohol in the blood depends on various factors. For instance, drinking modern beer of 5 per cent. strength to bring about real intoxication must in any case be a slow process, because of the large volume that must be imbibed to supply the necessary amount of alcohol. The amount of alcohol in beer that will take a normal man two hours to drink will be drunk with ease in five minutes in the form of whisky. During these two hours oxidation changes will be taking place in the body, so that about 10 c.cm. of the alcohol consumed will be removed each hour from the body. Thus the maximum point of concentration, apart from the question of dilution discussed above, will be lowered when the more dilute beverage is drunk. In considering any particular instance of slow drinking, as compared with rapid drinking, the two points must be considered: (a) how rapidly can the alimentary canal absorb the alcohol of the particular beverage drunk? and (b) how much alcohol will dis-

appear from the body in the interval? In all cases it can be said that the slower the rate of drinking and the more dilute the alcoholic beverage, the lower will the maximum concentration of alcohol in the blood and the more slowly will this be attained.

(c) *Food.*—All foods tend to depress the rate of absorption of alcohol from the stomach and intestines, and thereby lower the alcoholic concentration of the blood, but some have such a potent action in depressing blood alcohol as to appear almost specific. Among these foods

FIG. 3.—Resting experiment.

bread and milk stands out pre-eminent, as Mellanby has shown. It will be seen in Table A and in Fig. 3 that both bread and milk individually have this characteristic effect. It is quite certain that food in the stomach and small intestine greatly depresses the concentration of alcohol in the blood.

(d) *Size of Individual.*—Although it may be taken as a rough guide that the bigger the man the lower will be the concentration of alcohol in the blood produced by a definite amount of alcohol when all other conditions are constant, it does not seem to be always true. In Table B can be seen the maximum concentration in the blood of

TABLE B.

	Amount of Alcohol Drunk.	Dilution.	Max. Conc. of Alcohol in Blood mg. per 100 gr. Blood.	Weight in Kilos.
J. H. B.	96 c.cm.	8 per cent.	123 mg.	72
G. H. N.	"	" "	122 "	74
W. N.	"	" "	130 "	61
A. B.	59 c.cm.	20 per cent.	75 mg.	59.5
	"	" "	62 "	70

different men of varying weights after drinking alcohol when their stomachs were empty.

It will be seen that although in the case of J. H. B., G. H. N., and W. N. the alcohol concentration was roughly inversely proportional to their weight, in the case of A. and B. the ratio was reversed, the heavier man

having the higher concentration of alcohol in the blood when the same quantity of alcohol was drunk by each. It may be stated that A. was fatter at the time this examination was made than usual, his normal weight being about 70 kilos, and this may partially explain the discrepancy. The point needs further investigation. The blood and urine concentration curves for A. and B. are shown in Fig. 4.

(e) *Tolerance*.—It has been shown by Schweisheimer¹ that if abstainers, moderate drinkers, and heavy drinkers take the same quantity of alcohol when other conditions are equal, then the concentration of alcohol in the blood is highest in the abstainers and lowest in heavy drinkers. For some unknown reason the imbibed alcohol is never fully manifested in the blood stream of the alcoholic. Some of his results on these different classes of people are shown in Fig. 5. It will be seen that, although Case v drank

FIG. 4.

FIG. 5.—Four cases from Schweisheimer's paper.

about the same amount of alcohol as Case I (105 c.cm. as against 102 c.cm.), although their weight and ages were approximately the same, yet the maximum concentration of alcohol in the blood of Case v (heavy drinker) only reached 59 mg. per 100 grams of blood, as compared with 138 mg. per 100 grams of blood in Case I (abstainer).

The main conditions which influence the concentration of alcohol in the blood, so far as they are known, have now been described. It will be seen that, for a given quantity of alcohol drunk, increased dilution, slower drinking, food in the stomach and alimentary canal, and especially bread and milk, an increase in size of the individual (except possibly when increase in size is due to fat), and tolerance to alcohol as seen in the toper, all tend to depress the alcoholic concentration in the blood. It would appear that the maximum concentration of alcohol is produced by a given amount of this substance when a concentrated solution, say in the form of spirits, is rapidly drunk on an empty stomach by one unaccustomed to alcohol. It seems safe to say that if such a person of a known size develops a maximum alcoholic concentration in the blood of x mg. per 100 grams of blood when he has drunk y c.cm. of alcohol, then any other person of similar size found to have a similar amount of alcohol in his blood must at least have drunk a similar quantity or more of alcohol. Thus, by taking a number of normal individuals, such as has been done in the cases above of J. H. B., G. H. N., and W. N., and determining their blood alcohol

after drinking definite quantities in a concentrated form, on an empty stomach, it would be possible to find figures which would represent the minimum amount of alcohol which would produce a definite quantity of alcoholic concentration in the blood. For instance, a 20 per cent. solution of alcohol in the form of whisky containing 96 c.cm. of alcohol, produced, when drunk rapidly on an empty stomach, a maximum concentration of:

136 mg. per 100 grams of blood in J. H. B.
134 " " " G. H. N.
141 " " " W. N.

In these men, and in men of similar size, these concentrations of alcohol in the blood might be produced by imbibing similar quantities of alcohol, but, in practice, they would probably be due to drinking more than the quantity used in the experimental determinations, which are the optimum for producing the highest and most rapidly reached concentration.

Thus it would appear possible, from a determination of the blood alcohol in control cases known to have drunk specific quantities of alcohol under definite conditions, to decide that a concentration of alcohol in the blood of tested individuals could only have been produced as the result of drinking not less than a certain quantity of alcoholic beverage.

2. The Relation of Alcohol in the Blood to Alcohol in the Urine is Fairly Constant in many Circumstances.

Besides having the property of remaining in the blood for many hours after being drunk, alcohol has another characteristic in that, however small may be the quantity in the blood, a higher concentration appears in the urine within half an hour of ingestion. The kidneys cannot, in fact, restrain the passage of alcohol, but actually appear to concentrate it in its passage. So long, therefore, as alcohol is present in the blood after drinking this substance, alcohol can also be detected in the urine.

Nielow,⁶ Widmark,² and Ambard⁷ found that the concentration of alcohol in the blood and urine at any time was the same, but Miles³ showed that this was only so for about the first half-hour after drinking alcohol. After this time the concentration in the urine is always higher. My own figures corroborate, with larger quantities of alcohol and over a longer period, what Miles found with small quantities. In Table 'A' it will be seen that the ratio of alcohol concentration in the urine to alcohol concentration in the blood in the three subjects J. H. B., G. H. N., and W. N., after they had drunk an 8 per cent. solution of alcohol containing 96 c.cm. of this substance on an empty stomach, varied between 1.34 and 1.40 in six samples taken. Since these figures were obtained the writer has

FIG. 6.—Blood and urine alcohol concentration curves of G. H. N.

carried out further estimations at the hour and two and a half hour intervals. The mean from seventeen results at the one hour interval works out at 1.32 for the ratio,

and the mean of the ratio at the two and a half hour interval in thirty-one experiments works out at 1.37. Some of these results are shown graphically in Figs. 6 and 7.

FIG. 7.—Blood and urine alcohol concentration curves of W. N.

In Fig. 4, which shows the alcohol concentration in blood and urine of two other subjects, A. and B., after drinking 144 c.cm. of whisky containing alcohol in a dilution of 20 per cent., the mean ratio of alcohol in the urine to alcohol in the blood one hour after drinking the alcohol is 1.35. It may be accepted, therefore, that when alcohol is drunk on an empty stomach the ratio of these concentrations of alcohol after one hour is a fairly constant figure of the order of 1.35.

It is surprising how constant this figure is. In Table A it will be observed that, when the drinking of alcohol is preceded by drinking water or milk, or eating bread and milk, or bread and water, or olive oil, the ratio of the concentrations of alcohol in the urine and alcohol in the blood remains the same, the average being about 1.40. It would appear, in fact, that food makes no difference to this ratio.

It would be expected that diuresis would influence the ratio, but here again this does not seem to be the case. The following table gives the results of exactly similar experiments carried out on the same subject, but separated by an interval of seven months. In each case the man (J. H. B.) drank 1,200 c.cm. of 8 per cent. alcohol on an empty stomach. The resulting blood and urine concentration curves were practically the same in each case, but on the first occasion, for some unknown reason, he passed 500 c.cm. more urine in the experimental period. The following figures were obtained:

Ratio of Urine Alcohol to Blood Alcohol.			Total Volume of Urine passed in 6½ hours.	Mean Concentration in Urine.
1 hour.	2½ hours.	6½ hours.		
1.32	1.37	1.37	1,700 c.c.m.	148
1.34	1.35	1.39	1,203 "	146

The important point is that the increased flow of urine in the first experiment has not altered the ratio of the urinary and blood concentration of alcohol—a fact which Miles also noted. If, as seems to be the case, there is this fairly constant ratio between urinary and blood alcohol concentration under widely different conditions, all the circumstances described above, as influencing alcohol in the blood can probably be regarded as having an equal and similar effect on the urinary alcohol. Thus slower rate of drinking, the dilute alcoholic beverage, the presence of food, and especially bread and milk in the stomach and intestine, tolerance as the result of constant drinking—all these conditions will tend to depress the alcohol concentration of the urine. On the other hand, a concentrated solution of alcohol drunk rapidly on an empty stomach will give the maximum concentration of urinary

alcohol for a given quantity of alcohol imbibed. Thus, in this case also, it ought to be possible to say, on the basis of control experiments, that a certain concentration of alcohol in the urine can only be produced as the result of drinking not less than x c.cm. of alcohol.

3. The Concentration of Alcohol in the Blood is related to Symptoms of Intoxication of the Central Nervous System.

Increasing the amount of alcohol drunk increases both the alcoholic concentration in the blood and the symptoms of intoxication. Gréhant showed that with increasing quantities of alcohol drunk not only did the point of maximum concentration of alcohol in blood rise, but this remained for a longer time at a high level, thus forming a plateau—the so-called Gréhant plateau. At this stage the animal or man remained for long periods in the "dead drunk" condition.

In Fig. 5, which represents the result obtained by Schweisheimer on abstainers, and moderate and heavy drinkers, it is seen that the concentration of alcohol in the blood of heavy drinkers is much lower than that of abstainers when similar quantities of alcohol are drunk. Schweisheimer considered that this is the reason why the "topers" are less affected than the novices. The symptoms in each case are related chiefly to the amount of alcohol in the blood. One of his conclusions—for which, however, there is no actual evidence in his paper—is that symptoms of intoxication are exactly parallel to the increase and decrease of the alcohol in the blood. To illustrate this from an actual curve he maintained, for example, that the toxic effect of an alcohol concentration in the blood at A (Case IV), a point where the concentration is rising to a maximum, was the same as that at B, a point equal in concentration where the curve is falling. Mellanby pointed out as a result of his experiments that the intoxication at A is greater than at the same level B. Later Miles found a similar result with smaller amounts and weaker concentration of alcohol. This difference between the intensity of intoxication at points of equal alcohol concentration of the blood on the upward and downward curve is probably relatively small with higher concentrations of alcohol in the blood and urine, and does not prevent the blood alcohol being recognized as a fair measure of a man's condition of intoxication. How closely intoxication runs to the blood alcohol was shown by the amounts of alcohol in the blood of a subject of Mellanby who drank the same amount of alcohol under three different conditions: (A) in the form of 20 per cent. solution of whisky on an empty stomach; (B) in stout of strength 5.5 per cent. on an empty stomach; and (C) in stout of 5.5 per cent. strength, but taken two hours after the subject had eaten a basin of bread and milk. As might be expected from the earlier remarks, the concentration of alcohol in the blood was highest in (A), lower in (B), and more depressed in (C) by the bread and milk. Corresponding with these alterations in blood alcohol was the power of the subject to draw a simple diagram. After drinking whisky the rapid rise of alcohol in the blood was accompanied by great inco-ordination in the power to draw, and the descent in the curve by a corresponding recovery.

Referring back to Fig. 2, we see the difference in the maximum concentrations produced by different concentrations of alcohol, and the subject showed corresponding intoxication in the region of maximum concentration. After whisky he showed definite symptoms of gross intoxication. In the case of the 8 per cent. alcohol there were no symptoms of gross intoxication; but his powers of co-ordinating, as tested by Mellanby's method of getting the subject to reproduce a given diagram, were impaired for a considerable period. This same test, applied to the subject after he had drunk the beer, showed such small differences that they are not worth recording.

Method of Applying the Test.

From the experimental evidence given above it is concluded that a knowledge of the concentration of alcohol in the blood is the best guide to alcoholic intoxication. There are obvious objections to the direct method of obtaining the blood concentrations by taking blood

samples, but the above evidence shows that the indirect method of deducing the blood concentration from a knowledge of the urine alcohol concentration gives a close approximation. The problem is to estimate the blood alcohol concentration at the time of arrest. The time of arrest is always noted by the officer. On arrival at the police station the defendant is requested to empty his bladder completely. This specimen of urine should be kept and analysed, even though the resulting figure will give only the mean alcohol concentration over a previous period of unknown duration, but even this figure is of value. The important sample is the next one, which is obtained at the end of, for example, another fifteen minutes. Since only 5 c.cm. of urine are required for doing a duplicate test and for testing for sugar and albumin, the time interval required for this further secretion of urine is not a long one. Let us suppose it is fifteen minutes. Analysis of this sample will give the mean concentration for this interval, or the actual concentration at seven minutes from the time (which will have been noted) when the bladder was evacuated. If the figure 1.35 be taken as the ratio of urine alcohol to blood alcohol, the blood alcohol concentration at this seven-minute interval can be calculated. Knowing this figure and the time interval between the arrest and emptying the bladder, the blood alcohol concentration at the time of arrest is calculated from the fact that alcohol concentration in the blood falls at the rate of about 12 mg. per hour per 100 grams of blood.

There remains for discussion the question whether a blood alcohol concentration figure could be experimentally determined which could be considered as an upper limit as regards the fitness of a person to be in charge of a car. In the opinion of the present writer this is possible if suitable tests, especially those involving judgement, are carried out under actual driving conditions. It is suggested that a number of subjects, used to driving a car, be selected, among these being abstainers, moderate drinkers, and heavy drinkers. These could be put through a series of driving tests (to be decided upon) in such a school as, for example, that in which the drivers of the London General Omnibus Company are tested. If the efficiency of these individuals was determined by these tests before alcohol was given and then afterwards when alcohol had been given to each subject in sufficient quantity to produce approximately the same concentration in the blood and urine of each man, it is maintained that from the results obtained a maximum safety level could be fixed upon for the blood and urine alcohol concentration. It is suggested that this figure be used for comparison with that obtained at the time of arrest of the person accused of being drunk in charge of a car. The writer maintains that this is the only scientific method of estimating intoxication at the time of arrest. The experimental evidence given above shows that there is a basis for the method, which it is hoped may be tried out more fully and under actual driving conditions.

The method of estimating alcohol in the urine is that of Cannan and Sulzer.⁹ It is admirably adapted for such a test, as it can be carried out within half an hour and with as much accuracy as the fat in milk can be estimated. No bodies present in normal urine interfere with the estimation. The effect of the so-called acetone bodies is shown by Table C. It is obviously small, and a routine test with Fehling's solution at once puts one on guard.

TABLE C.

To Test the Effect of Substituting Acetone for Alcohol under the usual Conditions of Estimation.

26.5 mg. of acetone dissolved in 5 c.cm. of water were passed through the apparatus under the same conditions as when estimating alcohol. The result, calculated as alcohol, equals 3.1 mg. of alcohol.

Thus 8 mg. of acetone are equivalent to 1 mg. of alcohol under the experimental conditions.

Tests on Diabetic Urines, from Subjects who had had no Alcohol.

Case 1.—Symptoms severe—air hunger, etc. Urine contained 24 mg. (reckoned as alcohol) per 100 c.cm.

Case 2.—Symptoms not so severe. Urine contained 9 mg. (reckoned as alcohol) per 100 c.cm.

The result with pure acetone makes one doubt whether the 2 to 4 mg. of reducing substance present in normal blood is an acetone body, as has been suggested.

TABLE D.—Summary of Police Court Cases.

No.	Interval.	Urine Alcohol.	Police Remarks.
1	mins. 95	mg. 328	When arrested smelt of drink, was unsteady in his gait, and very talkative.
2	5	383.	This man was unsteady in gait, incoherent in speech, and appeared dazed. Stated he had been drinking spirits. Completely drunk.
3	72	380.5	This man was not able to walk without assistance, and was inclined to his left of drink, and he speak fairly clearly, and stated he had had at least eight pints of beer to drink.
4	15	257	This man had had a considerable amount of intoxicants. His breath smelled of drink. He was very talkative and inclined to be merry and boisterous. His speech was intelligent, and altogether I was of the opinion that he was a person used to taking quantities of alcohol. Certified to be fit to drive a car by police surgeon 45 minutes after arrest.
5	5	323	This man was unsteady in gait, particularly incoherent in speech, and very noisy. His breath smelled of alcohol, and he appeared a typical case of drunkenness. Said he had had six pints of beer.
6	5	232	Unsteady gait, breath smelled strongly of alcohol, quarrelsome.
7	30	356.5	Very talkative. Unable to walk without assistance and smelled strongly of drink.
8	10	316	Unsteady in gait, breath smelled strongly of drink. Inclined to be quarrelsome. Appeared a typical case of drunkenness.
9	10	349	Very unsteady in gait. Breath smelled of alcohol. Was quarrelsome and used obscene expressions.
10	4	315	Very unsteady in gait. Breath smelled very strongly of alcohol. Persisted in the use of obscene language in the cells. Also sang the "Red Flag" when not using foul language.
11	154	223.7	Face flushed, eyes bloodshot. Talked very excitedly, and refused to be seated when asked. Would persist in walking about the office. Smelled strongly of drink, and in order to try to keep a steady gait had to make forced movements of the muscles of his body.
12	23	321.6	Smelled strongly of drink, and stated he had been drinking bitter beer. Had almost lost control of his legs and could not walk without assistance. Did not show any stupidity, but talked all the time in a jocular manner.
13	7	361	Smelled strongly of drink, unsteady in gait. Had fallen and injured nose previous to arrest. Incoherent in speech; inclined to be merry and nasty alternately. Appeared generally to have had plenty of drink. Stated next morning he had had beer and then rum.
14	134	363.5	Unsteady in gait, smelled strongly of drink; said to have consumed several kinds of liquor. Was very drunk.
15	2	270	Unsteady in gait, smelled strongly of drink, sullen and rather quarrelsome. Was rather intelligent when spoken to, and able to give all particulars of himself.
16	13	326	Very unsteady in gait; incoherent in speech; breath smelled of alcohol (should say spirit). Eyes were not alert, but required effort to move. Used obscene expressions, alternating with snatches of song.
17	7	191	Very unsteady in gait; incoherent in speech. Appeared dazed and not able to speak intelligently; was not able to give any particulars of himself. Breath smelled strongly of drink.
18	10	331.6	Unsteady in gait, particularly incoherent in speech.
19	128	329	Incoherent in speech; unsteady in gait; eyes not alert. Breath smelled of alcohol. Inclined to be quarrelsome. Said he had had beer and spirits.
20	169	220.4	Flushed face; very excited; unsteady gait. Breath smelled of alcohol. When placed in the cell started singing, then slept for two and a half hours.
21	10	436.8	Incoherent in speech; very unsteady in gait; eyes very dull; seemed very stupid. Too drunk to give any account of himself. Could not stand without support.

TABLE D (continued).

No.	Interval.	Urine Alcohol.	Police Remarks.
22	mins. 14	mg. 164	Had been found on tramcar two and a half hours before and taken to hospital, where stomach pump had been used, the doctor stating he was drunk. Pale face, unsteady in gait. Breath smelled of alcohol. Gave particulars of himself intelligently.
23	195	326	The prisoner was in a helpless condition. Her breath smelled strongly of alcohol. Speech was incoherent.
24	15	172	Very unstable; unable to stand without assistance. Flushed face, incoherent speech. Must have had a considerable amount of alcohol.
25	65	278	Face very pale; eyes very wild. Excited when she first entered the police office. Calmed down when questioned. Smelled of drink. Unsteady in gait; had to be assisted to walk. Stupid at times, but showed no violence.
26	50	360	
27	55	367	

The above table (D) is a summary of the twenty-seven police court cases examined.

Most of these are cases of pedestrians suffering from gross alcoholic intoxication. The alcohol concentration figure given is, with the exception of Case 4, the mean figure for a previous period of unknown length. The motorist cases are numbers 4, 11, 26, and 27. These results illustrate some of the weaknesses in the present-day methods. In Case 4 the defendant had a blood alcohol concentration when arrested of at least 180 mg. The charge of having been drunk three-quarters of an hour earlier was dropped when the police surgeon examined him forty-five minutes after arrest and certified him to be fit to drive a car. In Case 11 no special sample was obtained—the figure was a mean concentration. Having ('unawares') driven his car on the pavement and knocked two people down, and on returning to the wrong side of the roadway having knocked down a cyclist, he could only confess his guilt. Case 26, one of those referred to in the Introduction, is that of the defendant said to be suffering from the effects of influenza; Case 27 is that of No. 26's passenger, who admitted his guilt.

SUMMARY.

We have given evidence to prove:

- (1) The inadequacy of present-day methods of estimating alcoholic intoxication, particularly that of the motorist, who, while showing no signs of gross intoxication, may yet be unfit through alcohol to be in charge of a car.
- (2) That the concentration of alcohol in the blood is the best measure we have of alcoholic intoxication.
- (3) That the concentration of alcohol in the urine is proportional to that of the blood under all conditions so far examined, and have shown that a fairly constant ratio holds which enables us to deduce one concentration from the other.
- (4) That it is possible by this means to obtain a close approximation of the blood alcohol concentration of a person at the time of arrest, and therefore of the degree of alcoholic intoxication.
- (5) That the work justifies tests being carried out to establish an upper limit of blood alcohol concentration for a person to be fit, after taking alcohol, to be in charge of a car.

It is with pleasure that I acknowledge my indebtedness to Professor Edward Mellanby, in whose laboratory my work has been carried out, for his help and criticisms. Also my thanks are due to the True Temperance Research Committee, who have defrayed the cost of my work.

PUERPERAL MORTALITY.*

BY

SIR EWEN MACLEAN, M.D., F.R.C.P.,

PROFESSOR OF OBSTETRICS AND GYNAECOLOGY, WELSH NATIONAL SCHOOL OF MEDICINE.

I READILY accepted the invitation of your chairman, Dr. Rocyn Jones, to be present at this meeting of the Monmouthshire Division because, as one of my colleagues on the Welsh Consultative Council, I know him to be keenly interested in the subject of puerperal mortality, and I gather the intention is that I should offer some observations, by way of preamble to the discussion, by the Division, of the interim report of the Puerperal Morbidity and Mortality Committee of the British Medical Association, of which I have the honour to be chairman.

It is admitted, as regards both mortality and morbidity, that there is much room for betterment in this important sphere of medical practice, and that we in Wales and Monmouthshire have especial reason to give the subject our closest and most earnest attention. I feel sure, Sir, that you, in the influential role of county medical officer, must feel as I do in the capacity of a teacher, and as, I believe, those more highly placed in official circles must also feel—that it is easier to fulminate against the general practitioner or the midwife, or both, from the lectern or office chair than to strive, in season and out of season, to render available those conditions of service which are essential for the elimination of many of the factors contributory to the mortality and morbidity rates.

It is undoubtedly true that, if it were possible, a zealous, unvarying application in all the phases (including antenatal) of midwifery practice, and by all persons and bodies concerned therewith, of that knowledge which we already possess would result, even in prevailing environmental conditions, in striking improvement. It is true, too, that, short of this ideal unity of effort, each of us can contribute his quota toward improvement by conscientious use of that knowledge.

Unless and until, however, further knowledge emerges to illumine some aspects of the problem, there will still always remain a mortality rate sufficiently large to engender concern. It was this consideration, I think, which led the Puerperal Morbidity and Mortality Committee of the Association to submit to the Council a recommendation urging that provision should be made for investigation into the factors which constitute and the conditions which vary resistance to disease, particularly as regards pregnancy and the puerperium. The Council readily concurred, and the recommendation has been referred to the Science Committee of the Association.

The principle underlying the oft-quoted legend which spans the portals of the New York Health Department—to the effect that public health is purchasable, and that, within limits, a community can determine its own death rate—has a very real application to the State responsibility aspect of this question.

To provide those requirements in personnel, equipment, and institutional accommodation, to name no others, which, by common consent, are essential to further lasting improvement in puerperal mortality and morbidity, means money in substantial amount; and let me add that whilst the professional services rendered must be met, in order to secure efficiency, with adequate remuneration, the expenditure under that heading would be by no means the largest item.

In health matters, as in some other concerns, it is extraordinarily difficult to arouse genuine and sufficiently sustained public interest. It took many years of propaganda work, acting on the principle of the summation of stimuli, to convince the public, and, indeed, many members of our own profession, of the need of the Midwives Act, and to bring home the fact that on the date of securing that enactment we were many years behind other civilized communities.

In its own effective, though perhaps undiscerning, way an aroused public opinion will ultimately insist on Parlia-

* Paper introductory to a discussion by the Monmouthshire Division of the British Medical Association, February 26th, 1926.

ment devising such economies in other directions as will permit of the necessary funds being provided. I confess, however, to hearing the other day that during the proceedings at a women's political conference, when the question of national expenditure was under consideration, a rhetorical appeal from the platform, "Shall we have battleships or babies?" was met by the reply from one lady, "Give me a battleship every time."

That phase of the genius of our country which is expressed in the evolution and development of our voluntary hospital system, as we know it to-day, has blinded successive Governments to their obligation to provide, as the Governments of other countries have provided, adequate moneys to cover the expenses of trained personnel, of equipment, and of premises concerned in the conduct of the costly research into matters concerning the health of the people. A few years ago a beginning was made in the establishment of the Medical Research Council, but the funds at the disposal of that very able body represent a small proportion only of the amount which could and should be expended. In this, as in so many other spheres of good service, voluntary effort has blazed the trail and is working towards the development of a highway, and I can imagine no more beneficent or hopeful project to endow than the research along the lines which are now contemplated.

There are not a few signs which go to show that good results are following the propaganda of recent years, and that as experience accumulates we ourselves, as well as those even more directly concerned—to wit, the mothers—are becoming more convinced of the value of ante-natal observation, advice, and, where necessary, treatment.

The public ultimately judges by results, and where, consciously or subconsciously, it is apprehended that, in given smaller or larger areas, ante-natal attendance is followed by a very real diminution in the incidence and gravity of the diseases and accidents of childbirth, there is no lack of patronage of the clinic or of the surgery. An essential condition, however, to a successful degree of appreciation by our patients of ante-natal attendance is their knowledge of the availability, should occasion arise, of adequate facilities for any necessary treatment, institutional or otherwise. I know of several instances where the knowledge of the provision of the contingent use of maternity beds has multiplied the ante-natal work in private practices and at the clinics of local authorities.

The absence of this principle of the "carry-through" provision constitutes, in my opinion, one of the heaviest handicaps to anything like efficiency in the notification of "puerperal fever," and an effective system of notification is essential to the success of our attack upon the largest single factor in puerperal morbidity. A later report from the committee will deal with this highly important subject, which, it is believed, is now engaging the anxious attention of the Ministry of Health.

The difficulty must be to decide whether notification shall apply to (a) cases in which diagnosis of puerperal infection may be presumed to have been established, or (b) all cases of sustained puerperal pyrexia. If the former, then the indications for early treatment and the prevention of the spread of infection may well be prejudiced; and if the choice be for the latter method, then, though the notification may be early, the many cases to be investigated and the many processes to be brought into play in their investigation may overwhelm even a large and costly addition to the administrative machinery existing at present, or even, indeed, that contemplated by the different schemes which the amazing overlapping of the various health agencies is forcing on to the screen.

It is truly difficult to comprehend, from consideration only of the bulk of the work involved, how the local authorities can be expected to comply with the recommendation that there should be an investigation in every area by a competent and experienced medical officer of all maternal deaths, and of all cases of puerperal fever, and all stillbirths and neo-natal deaths, with a view to ascertaining and preventing the causes likely to lead to maternal or infantile mortality.

I think it will be agreed, too, that the amount of the work would not be the only handicap to the satisfactory

discharge of this added range of duties. While practitioners and midwives must bear their share of the responsibility for the breakdown of notification, it must be borne in mind that, under prevailing conditions, objection is frequently raised by the lying-in woman herself or by her relatives and friends. Notification which results in nothing beyond visitation by various officials cannot be other than unpopular, but if and when it is followed by helpful service, and, where necessary, institutional treatment, the prospects of its acceptance and efficiency are assured.

Again, the existence and even the persistence of a rise of temperature in childbed is far too often regarded by the patient and her friends with the minimum of concern. I know, indeed, of some rural areas in Wales where lingers still a tradition that a mother recently confined *must* have a rise of temperature, the condition being dignified by the title "brad-gyfarfod," which, my friend Dr. Llewelyn Williams tells me, freely translated may be taken to mean "a combative meeting." The lochia and the mammary secretion are regarded as the principals in the combat. The mists of such superstitions and of many harmful practices based on ignorance are rapidly disappearing in the light of the wise propaganda conducted by many of our colleagues, by the health authorities, and by the various philanthropic bodies, and an informed public opinion not only asks why, if this mortality and morbidity are in large part preventable, they are not prevented, but is, I believe, ready as never before to support by practice and precept all reasonable measures to make that prevention an objective. Our duty as a profession is to strive, individually and collectively, to meet that aspiration so as to secure the best possible results.

The British Medical Association has taken the matter in hand, as one of profound importance, and our Committee is in touch with the overseas Branches. It has become, indeed, an international concern. It is gratifying to observe the many signs that the Interim Report has aroused the deep interest of our Divisions and Branches, for I am convinced that our Association is the only body which can mobilize the profession to make a real and effective advance, not only in matters medico-political, but also toward the solution of this problem, which intimately engages all its spheres of work, from the most technical bacteriological and biochemical research, through the ranges of hospital practice and investigation, to the clinic and the ultimate domicile.

The Divisional replies to the questionnaire will be analysed by the Committee, and before a further report, with recommendations, is submitted to the Council, the Committee hopes to have the great advantage of conferring with representatives of the Ministry of Health, the Medical Research Council, the Obstetrical and Gynaecological Section of the Royal Society of Medicine, the Society of Medical Officers of Health, and the Central Midwives Board, to which bodies the Council will issue invitations. The report and recommendations will in due course come before the Representative Body after consideration by the Divisions.

I want to see our powerful Association throwing its whole weight into this great problem, which seems to me to call for its influence in initiating research, its unrivalled capacity through the Divisions for initiating or amending clinical methods, and its experienced medico-political skill—in other words, the basis, the adjutant, and the vehicle of a life- and health-saving combination.

It is sometimes forgotten that the Association, as such, is by far the largest purveyor to the profession in this country of all that concerns the practical application of the science and art of medicine, and I have heard it suggested that a logical development of that status would find a much appreciated expression in arrangements by the Association whereby demonstrations may be given, as occasion arises, of any of the newer clinical methods of investigation or treatment. Such demonstrations could take place at convenient centres (hospitals or other buildings) in London and throughout the provinces. I can well believe that such provision would be of eminent service in connexion with the topic we are considering.

There are not a few who regard the outstanding medico-political achievements of the Association as an over-developed salient, and that the general line, including the

clinical interests, needs bringing up. I am a firm adherent of the policy of the salient, but the extent to which we bring up the line is the measure of our consolidation in the confidence of the profession and the esteem of the whole community.

MATERNAL MORTALITY AND MORBIDITY.*

BY

LOUISE McILROY, M.D., CH.B.,

PROFESSOR OF OBSTETRICS AND GYNAECOLOGY, LONDON SCHOOL
OF MEDICINE FOR WOMEN.

THE passing of the Midwives Act in 1902 was an epoch-making event. I hope that the two reports—that by Dame Janet Campbell, issued by the Ministry of Health, and that by the Scottish Committee—will lead to other reforms of almost equal importance. In 1923 living births numbered 758,131 and maternal deaths 2,892, or 3.81 per 1,000. Of these, puerperal sepsis accounted for more than one-third, and eclampsia for one-ninth, so that deaths from other causes were 1,552, or about 2 per 1,000. But, as every practitioner knows, these figures do not tell the whole story. They do not indicate the terrible amount of ill health due to pregnancy, much of which is avoidable. I cannot, however, acquiesce in the opinion that the profession is entirely to blame. Until a comparatively recent date education in midwifery was meagre, and the practitioner, when qualified, was not as well equipped as he might have been to deal with midwifery. It redounds to the credit of the general practitioner that in most cases the defective education has been effectively supplemented by observation and practical experience. If the British accoucheur be compared with those in other countries it will probably be found that he is the best; for reasons which influence Dame Janet Campbell I place small reliance on comparative international figures.

In considering the progress of midwifery and the credit due to those engaged in its practice, we must remember that the fall in the infantile mortality rate from 154 in 1900 to 77 in 1922 is due in no small measure to improved obstetrics, by means of which hundreds of thousands of mothers have been enabled to produce healthier children. This is so even in spite of the stationary mortality of the first month. It may also be pointed out that the comparison between the general death rate and the maternal mortality rate may be fallacious, as it does not follow that there was the same room for improvement in the latter. We know, for example, that there was a great wastage of infant lives which should have been preserved, and the saving of these has been chiefly responsible for reducing the general death rate. There is no evidence of any such preventable wastage in maternal lives.

As concerns morbidity, it is not possible to compare one period with another. There is, however, good reason for believing that morbidity has decreased and is steadily decreasing. Progress may not be as rapid as we desire, but if our efforts have not been successful in reducing morbidity it is obvious that our methods must be radically wrong. It must, however, be admitted that maternal mortality and morbidity are partly due to ignorance, carelessness, and undue haste on the part of doctors and midwives. The cases quoted in Dame Janet Campbell's report make sad reading, but they represent only a minute fraction of a vast total of midwifery. Other branches of the profession have their inefficient followers, but it is easier to detect obstetrical errors. We can only look to improved education and the inculcation of higher ideals to remedy these evils. In other directions also there is much to be done. Maternal mortality and morbidity are no doubt largely influenced by bad housing and economic or industrial conditions. This, however, is not the place to deal with those questions. I propose to confine myself to the medical points.

First. I look to the extension of ante- and post-natal work as the most effective means of improvement. There is no need to dilate on the advantages of ante-natal

examinations and treatment, but it may be well to urge the importance of "after-care" in the interests of both mother and child. The continuance of breast-feeding is most important, and this cannot be ensured unless the mother is kept under the observation of the obstetrician for at least a month after the child is born. The post-natal (or rather the maternal and neo-natal) clinic also affords the means of studying and rectifying injuries and other illnesses due to labour. Ante- and post-natal clinics should not be confused with child welfare, and should be staffed by practitioners experienced in obstetrics. No person can carry out ante-natal work who has not been trained. It is a very difficult branch of medicine, and requires much skill and judgement in diagnosis. An intensive campaign should be organized to teach people the advantages of ante-natal work, which can be demonstrated by simple examples. For instance, toxæmia can be controlled or avoided and eclampsia almost eliminated by early recognition and appropriate treatment. The risks of labour in cases of pelvic abnormality may also be obviated or reduced. Steps must be taken to improve and extend the teaching of ante-natal methods for the benefit of both medical students and pupil midwives.

Second. While education in midwifery has improved, much remains to be done. For instance, one great defect is the absence of any clinical test at the final examination. But above all we must have facilities for post-graduate training of young practitioners and for refresher courses for older ones. We do not want more lectures, but facilities for clinical work and the actual handling of patients under the supervision of competent teachers. For this purpose we require one or more well equipped maternity hospitals, solely devoted to the instruction of graduates and staffed by experts who would serve only for limited periods, so as to give persons attending for instruction opportunities for studying different methods. It is sad to think that, considering all the material available in this country, anyone desiring instruction of this sort should have to go to Vienna or Paris. As 60 per cent. of the deliveries in this country are made by midwives, it is most essential that their education also should be improved by increasing clinical facilities that will enable them to see and take part in practical obstetrics of the best type.

Third. The provision of more beds for abnormal cases and for women who desire institutional accommodation owing to housing difficulties. The material thus provided could be utilized for educational purposes.

Fourth. We now come to that mysterious subject sepsis, of which, though it is a notifiable disease, there is no workable definition. At the same time, generally speaking, we know only too well the class of symptoms which come under this name. We also know, partially at any rate, the cause. We know that sepsis may be contagious and exogenous, and that to a great extent it may be avoided by cleanliness. On the other hand, we are satisfied that sepsis is also endogenous, but we do not understand how it arises in these circumstances. In the time at my command I cannot discuss technical details. I may say, however, that there is every reason to believe that streptococci that may be harmless when living upon a healthy unbroken epithelium change their character and become dangerous when allowed to feed on a bruised or broken surface. There are other possible causes of sepsis demanding investigation, notably the effect of intercourse during the later months of pregnancy and the after-effects of venereal disease. We are also faced with the strange and inexplicable fact that women who live and have their children in dirty surroundings do not suffer more from sepsis than those who live and have their children under the best possible conditions. Both classes suffer from contagion, but it is questionable whether the former class is not less liable than the latter, provided no operative intervention has been carried out. When we come to the endogenous type, either there is no difference between the two classes, or if there is a difference it is in favour of the women who live and have their children under apparently unfavourable conditions. All this requires elucidation, and more facilities for research are necessary—research especially directed towards immunity and the defensive nature of the bacteria of the genital tract. The course and treatment of sepsis we understand

* A paper (slightly abridged) read in opening a discussion in the St. Pancras Division on the interim report of the British Medical Association Committee on Causation of Puerperal Morbidity and Mortality, published in the SUPPLEMENT of January 9th, 1926.

fairly well. What we want to know is the cause of the endogenous variety. If this could be discovered we might reduce maternal mortality by one-third. This is an object upon which expenditure is worth while. The saving of 1,100 women's lives is no small matter.

Fifth. The existing organization of midwifery is more or less chaotic, and there is a lack of cohesion between the local authorities on the one hand and medical practitioners and midwives on the other. The midwife can call in any doctor she thinks fit. He may be experienced or may not, and there is no adequate supervision by the medical profession of the midwifery service as a whole. Panels of medical practitioners specially experienced in midwifery should be set up, and except in cases of emergency the midwives should be restricted to the members of these panels. Each patient should be seen by a medical practitioner at least once during her pregnancy. There should also be attached to every panel one or more specialists whose opinion could be sought in cases of exceptional difficulty. Every case of death in childbirth should be reported and investigated, so as definitely to ascertain the cause and whether the treatment has been as it should. Ante- and post-natal clinics and child welfare clinics should be co-ordinated. More beds should be provided for difficult cases, and arrangements made to pass on from the ante-natal clinics those women whose confinements are likely to be difficult. Cases of sepsis should not be treated in fever hospitals, but in open-air isolation wards of maternity hospitals.

That the mortality rate is exceptionally high in sparsely populated districts proves the advantages of skilled and prompt attendance. Steps should be taken to remedy these conditions by a more comprehensive system of administration; and here again the value of ante-natal work is apparent. If every expectant mother were to present herself for ante-natal examination by a medical practitioner, arrangements could be made, even in sparsely populated areas, to provide her with the necessary assistance.

In conclusion, let me say that there is no occasion for despondence, but every reason for hope. Statistics are dangerous things. For instance, the Scottish figures are most depressing, showing as they do that deaths from puerperal causes in Scotland have increased since 1855 from 4.9 to 6.2 per 1,000 births. I do not believe that these figures accurately show the state of affairs. I cannot believe that more women die from childbirth to-day in Scotland than in 1855. These figures depend on classification and knowledge on the part of the medical attendant. Even in an obstetric hospital we find it difficult to tabulate the diseases of pregnancy, notwithstanding an elaborate system of cross-indexing. This applies particularly to venereal diseases.

These matters demand urgent practical attention. Whatever criticism there may be on either side, we all have the same object in view. We are all anxious to improve the midwifery service and to save human lives.

THE TREATMENT OF SEVERE AND PERSISTENT UTERINE HAEMORRHAGE BY RADIUM.

WITH A REPORT OF 200 CASES.

BY

SIDNEY FORSDIKE, M.D., B.S., F.R.C.S.,

SURGEON TO OUT-PATIENTS, SOHO HOSPITAL; GYNAECOLOGICAL SURGEON TO KENSINGTON GENERAL HOSPITAL.

THE type of haemorrhage under consideration is frequently described as idiopathic or essential haemorrhage, and pathologically it is referred to as chronic metritis, fibrosis uteri, or chronic subinvolution; but, however debatable the pathology, the one distinctive feature is the excessive and uncontrollable haemorrhage with absence of any pelvic lesion to account for it. This series of cases does not include the minor uterine haemorrhages which are relieved by drugs or a single curettage, but only cases which had been dealt with in the ordinary way and proved refractory. In many of the cases I have myself performed curettage in the hope that it would alleviate the condition, and

only used radium when it was subsequently found that the operation had had little or no effect. The cases were chosen for the following reasons:

- (1) The persistence of uterine haemorrhage after prolonged medical treatment.
- (2) After curettage or other operation with no relief.
- (3) Advanced degree of anaemia, with shortness of breath, headaches, oedema of the legs, etc.
- (4) Cases in which the patient had to spend some part of each month in bed on account of the severity of the haemorrhage.

Analysis of this series of 200 cases shows the following reasons for the treatment:

	Cases.
Dilatation and curettage ...	96=48.0 per cent.
Other operations ...	20=10.0 "
X rays ...	1= 0.5 "
Confined to bed for part of life ...	12= 6.0 "
Anaemia ...	38=19.0 "
Palliative treatment failed ...	33=16.5 "

A large number (48 per cent.) had already been treated by dilatation and curettage, of which 8 had been curetted twice, 4 three times, and 2 five times. Blacker's records a case where the patient had been curetted eighteen times. It seems hardly credible that this operation could be repeated four, five, and more times; nevertheless it is frequently done. It is reasonable to repeat it once where a patient has derived considerable benefit from it for months and is nearing the menopause, but there can be little reason for pursuing it beyond this point.

Twenty cases had undergone some other form of operative treatment, including excision of polypi, amputation of the cervix, resection of cystic ovaries, ventral suspension, salpingectomy, appendicectomy, and myomectomy—the best results being relief for a few months, and the poorest no relief at all. One patient (Case 5) had been curetted, and, this proving of no avail, was subsequently given five exposures of x rays, the details of which I did not learn; she improved for a few months, relapsed, and was then successfully treated by radium.

Twelve cases (6 per cent.) were almost completely bed-ridden, and spent the greater part of their time between bed and a couch.

Thirty-eight cases (19 per cent.) were in an advanced degree of anaemia through continuous loss. One (Case 17) had been treated palliatively and later by curettage; after the operation the bleeding did not stop and she was becoming seriously ill. The surgeon had had her prepared for hysterectomy, but as I was in the hospital that morning treating another case he asked me to see her. We decided to give her the chance, and radium treatment was carried out. After one exposure temporary relief occurred, and five months later a second exposure was given, which established amenorrhoea permanently.

Case 66.—This patient, aged 18, had been an in-patient and out-patient at a general hospital for sixteen months, but she continued to lose excessively 8-10 oz. This was aggravated by intermenstrual loss, and culminated in a five weeks' continuous and severe haemorrhage. She was seen at her home in consultation by one of my colleagues, and immediately sent to hospital in an ambulance. She was colourless, breathless, and looked to be in a moribund state. A blood count showed: red blood cells, 2,200,000 per c.mm.; white cells, 12,000. She was given 100 mg. of radium bromide for twenty-four hours. Amenorrhoea ensued for three months; then she had irregular periods of five-day type for five months, and then became, and remains, regular every four weeks of the five-day type. This patient had what is known as the haemorrhagic diathesis, for extraction of a tooth was followed by troublesome haemorrhage and the socket required repeated plugging; she bruised very easily, but no gross internal haemorrhage had been noted. It is also interesting that during her period of amenorrhoea she had attacks of epistaxis.

History.

This condition may occur at any period of menstrual life, but is more commonly found at and around puberty, between 30 and 40 years of age, and at the menopause. The clinical picture is that of menorrhagia and metrorrhagia, and the period may be so prolonged that the patient finds it easier to describe how many days in the month she is clear, rather than to describe how long the haemorrhage lasts. Finally, she may have to spend most of her time in bed on account of the haemorrhage and consequent anaemia.

Of 50 of these cases submitted to the Wassermann test, not one showed a positive reaction; I do not therefore believe that syphilis plays any part in the etiology. In later life a large majority of the patients are parous women, so the possibility that infection plays a part must be admitted, although histological evidence is not obtained; but when it is remembered that this condition is not so uncommon at and around puberty (I have curetted and treated 16 cases), previous infection by gonococcal and pyogenic organisms cannot be a constant factor.

Pathology.

Clinically two types of uterus are met with in this condition—the systolic and the diastolic.

(a) *The systolic uterus*, which is but slightly if any larger than the normal organ, is hard, heavy, and regular in outline, with a cavity $2\frac{1}{2}$ to 3 inches in length; it yields little or no tissue to the curette, but gives a characteristic rasp as the metal loop passes over the surface. It has commonly lost its flexion, and is perfectly straight, with a greater or less degree of retroversion. On section the wall may be as much as an inch in thickness, and the arteries are prominent, with gaping mouths and quite incapable of collapse; if a portion of one of these vessels be dissected out of the uterine wall it will be found to retain its patent condition.

(b) *The diastolic uterus* is bulky and retroverted, with a cavity varying between $3\frac{1}{2}$ and 5 inches, and yields a considerable quantity of thickened, oedematous tissue to the curette. It occurs in parous women, and most often as they are approaching the climacteric. After curettage the hyperplastic endometrium slowly re-forms and the symptoms return. These patients frequently undergo curettage two, three, or more times, in the hope that it will tide them over until the menopause sets in. It is a condition which is almost certainly cured by exposure to radium. If the patient be examined some months after the exposure to radium, when amenorrhoea is fully established, the uterus will be found to have contracted down to the size of what I have called the systolic uterus.

Of the series of 200 cases, 64 (32 per cent.) belong to the systolic group, 18 of which were nulliparous women; 120 (60 per cent.) belong to the diastolic group, of which 8 were nulliparous; and of these 184 cases 30 had small fibroids. In the remaining 16 cases an attempt was made to control the haemorrhage rather than to establish amenorrhoea.

Diagnosis.

The diagnosis must necessarily depend upon the result of an exploratory curettage, the exclusion of new growth, the absence of any other pelvic lesion which would induce haemorrhage, and upon the physical characters of the uterus as determined bimanually and by the curette.

Analysis of Cases.

In nearly all cases at or near the menopause (128 cases = 64 per cent.) one exposure, the dose of which I will discuss later, sufficed to establish amenorrhoea. Three cases were given a second treatment before amenorrhoea was established, and one case required three exposures. Late recurrence took place in some of these cases, but they will be mentioned later. Of the 200 cases, 14 (7 per cent.) in all required two exposures, and 6 (3 per cent.) required three exposures before the menopause was induced, but they occurred for the most part in the younger women. The ages were as follows:

		Cases.	
16-29 years	...	18	= 9 per cent.
30-35 "	...	20	= 10 "
36-40 "	...	52	= 26 "
41-45 "	...	46	= 23 "
46-50 "	...	42	= 21 "
51-55 "	...	22	= 11 "

It is important to notice that practically all the cases which were refractory to a single treatment occurred in young women. In two cases (Nos. 76 and 110) hysterectomy was done.

Case 76.—A single woman, aged 21, had haemorrhage of a severe type ¹⁰⁻¹¹ for some years, which had gradually got worse. Two years before she came under my care she had her appendix removed, after which the periods lasted fourteen days, and four

months before I saw her dilatation and curettage was performed. Following the last operation the haemorrhage did not cease and she lost more or less daily. On July 17th, 1923, I examined her under an anaesthetic, and found a small firm uterus, $2\frac{1}{2}$ inches in length, which yielded no scrapings and gave the characteristic rasp of fibrosis uteri. I decided to try and modify the periods rather than abolish them, and introduced 50 mg. of radium bromide into the uterus for twenty-four hours. She had a prolonged show through August and September, which became severe at the end of this month and the beginning of October. On October 8th I again introduced 50 mg. into the uterus for twenty-four hours. She remained free for a month and then had irregular losses, becoming gradually worse until January, 1925.

On January 23rd, 1925, I introduced 100 mg. of radium bromide into the uterus for twenty-four hours, but she continued having irregular losses until July; she then came determined to have hysterectomy performed, and if I would not agree she was going to another surgeon. On September 16th I performed complete hysterectomy. I now think it probable that had I given her a large dose at the outset the subsequent history would have been different.

Case 110.—A single woman, aged 51, had severe and irregular haemorrhage for nine months. Dilatation and curettage were performed. The uterus was retroverted and enlarged $3\frac{1}{2}$ inches. Scrapings were sent for microscopic section. The report was that there was no malignancy. Ten days later I introduced 100 mg. of radium bromide into the uterus for twenty-four hours. She had two shows after this, followed by amenorrhoea for ten months. She then began losing again, and consulted another surgeon, who performed subtotal hysterectomy. The uterus contained no growth and the endometrium was hard and firm. I did not see the patient again after the treatment by radium, but judging from the condition of the uterus after removal, I think the cause of the recurrent haemorrhage ten months after radium would be found under the group "causes of late recurrences," to be discussed later.

Thirty cases were complicated with fibroids, all small in size and no larger than a Tangerine orange, some of which were only diagnosed by the curette; all did equally well with the non-fibroid cases. In the ordinary way I believe that any case of fibroid tumour of the uterus which calls for treatment at all requires either myomectomy or hysterectomy, according to the age of the patient, and should not be treated by any form of radiation; for although the tumour shrinks and the haemorrhage ceases, the character and extent of degeneration in the tumour cannot be foretold, and it is much wiser to remove than to leave it. There is one exception to this view—a patient who is very anaemic through loss of blood should have the haemorrhage controlled by radium pending the restoration of her blood picture. Cases have been recorded where fibroids the size of a five months' pregnancy have been irradiated, with the result that the tumour has shrunk into a pelvic tumour; this is not entirely satisfactory, for I have operated upon one such case in which the pelvic fibroid was producing pressure symptoms.

I have treated 16 young women (18 to 26 years of age) with the object of modifying the period rather than abolishing it; 12 became normal after varying periods of amenorrhoea, 3 remain amenorrhoeic (five, seven, and nine months), and one had hysterectomy performed.

The group between the ages of 30 and 35 numbered 20 (10 per cent.): 6 of these required two exposures before amenorrhoea was established; 6 others after varying periods of amenorrhoea became normal in type; 4 were given prolonged exposures (forty and forty-eight hours) so as to ensure amenorrhoea; the remainder behaved normally, amenorrhoea being established after the initial dose. In this group again it was found that the younger the patient the larger the dose required, and it emphasizes the observation that it is difficult to induce amenorrhoea in young women by medium doses.

Technique.

Various methods have been described—namely, placing the radium in the uterus, vagina, and upon the abdominal wall. Blacker² describes application to the abdominal wall as well as to the interior of the uterus; any action produced in this way must necessarily be upon the ovary, which we desire to avoid, and, in addition, it must be very uncertain. Since his paper was published I note that the annual report from University College Hospital indicates that this method has been abandoned.

Prolonged exposures in the vagina are fraught with danger of fistula formation, and I know of two cases of vesico-vaginal and recto-vaginal fistulae produced by this method, both from the same clinic. I have no experience in these two last methods, all my cases having been

treated by the intrauterine method, and I have never seen a fistula follow it. Finally, the results from radium *in utero* are so constant and satisfactory as to place other methods which are open to criticism beyond the scope of clinical practice.

Anaesthesia.

Whatever treatment be adopted for this condition, anaesthesia is required for an imperative exploration of the uterus, and the radium in suitable cases is introduced at the same time. Where a second or third exposure is required it can be introduced into the uterus without another anaesthetic after softening the cervix with glycerin plugs.

In all cases dilatation of the cervix and an exploratory curettage is done, and any tissue removed is referred for microscopic examination. In all cases the radium is screened in brass or lead to exclude all except the gamma ray, and the tube is then surrounded with rubber tubing 2 to 3 mm. in thickness to exclude secondary rays. The radium is placed in the uterus, and the vagina is plugged with gauze soaked in liquid paraffin, with the twofold object of keeping the radium in position and maintaining the bladder and rectum as far as possible from the source of energy. A further precaution is taken to maintain the bladder in a flaccid condition by the introduction of a self-retaining catheter into the viscus and leaving it there until the radium is removed. In some cases it is necessary to stitch the vulva in order to support the vaginal plug. In cases of advanced anaemia the patients are kept in bed for three weeks, but in ordinary cases the patients are allowed up at the end of three days and sent home at the end of a week.

Dosage.

The determination of the adequate dose cannot be stated in a general way, for each case must be considered on its merits. While excessive dosage does not show itself in the same way as the narcotics do, nevertheless radium is capable of producing severe burns if administered in ill considered doses; and such burns, although *in utero*, may subsequently declare themselves as a source of infection, producing symptoms which are difficult to explain unless such a lesion is considered. Later, following such burns, pyometra may result.

In women at or near the menopause 100 mg. of radium bromide, enclosed in 0.5 mm. silver and 1 mm. brass or lead wrapped up in rubber tubing 2.3 mm. thick, is given for twenty-four hours, and is commonly successful; but when a great deal of blood has been lost and it is of urgent importance to stop the haemorrhage the radium may be left in for thirty-six or even forty-eight hours. Again, in cases of fibroids I give a minimum exposure of thirty hours; these doses invariably prove satisfactory, and a second treatment is rarely required.

In dealing with young women I was much less sure of my ground. In my early cases I was afraid of producing permanent amenorrhoea, and gave treatments of 50 mg. of radium bromide for five, six, eight, or ten hours, and was surprised to find how small an effect was produced; but with increased experience I found that it was a much more difficult problem to induce amenorrhoea in them than in the menopausal women. In certain urgent cases I gave exposures of 100 mg. for twenty-four hours, which succeeded in establishing amenorrhoea for a short time, but then the periods returned (Case 66). Several other cases behaved similarly, and now I have little fear of producing permanent amenorrhoea in them.

Symptoms during and following Exposure.

While the radium is in the uterus the patient may complain of a pain which she likens to the onset of a period, or to the pain complained of whilst a stem pessary is in position. It is tiresome but not unbearable, and is immediately relieved when the radium is removed; it is due to contraction of the uterus in an effort to expel a foreign body. In sensitive patients it may require the administration of a sedative, and there is no reason for withholding it.

Vomiting may be a pronounced symptom and take the form of a prolongation of anaesthetic vomiting; it never

becomes serious, and ceases abruptly with the removal of the radium.

Temperature.—There may be a small rise of temperature to 100°, which persists for a day or so, and is probably due to some absorption from the closed uterus.

Haemorrhage.—When the exposure is given immediately before the onset of a period, the haemorrhage consequent upon the curettage may pass directly into the monthly flow. This period is prone to be a very severe one, accompanied by flooding, and may necessitate plugging as in Case 28. The common history, however, is a prolonged show of two to three weeks' duration, followed later by a second show, and then amenorrhoea. A fair number will experience a third period, or two or three irregular losses, but where one exposure is going to succeed there is rarely more than this. Generally speaking, three months must elapse before the full result can be estimated, and where haemorrhage persists beyond this further treatment will be necessary.

Leucorrhoea invariably follows the treatment, and in some cases produces irritation of the vulva. I order all patients to douche themselves with two quarts of salt and water daily for six weeks, and at the end of this time the leucorrhoea has practically disappeared; but in cases complicated with a fibroid the discharge may last longer.

After-History.

There is not infrequently a complaint of painful micturition, which quickly passes off with the administration of barley water and a mixture of urotropine, and is probably due to the irritation produced by a catheter in the bladder. I have not met late rectal or vesical symptoms in these cases, probably on account of the moderate dose employed and careful packing of the vagina. Bonney³ frequently quotes fistula formation as an after-result; if this were a danger in the intrauterine method it is quite certain that I should not have escaped the experience in 230 cases, of which somewhat less than 1 per cent. are unaccounted for.

Contraindications.

The sole absolute contraindication to the use of radium in this condition is the presence of pelvic inflammation, and this is a very real danger, for the pelvis may become filled with an inflammatory tumour, the nucleus of which is a deeply seated abscess and the walls composed of uterus, bladder, and bowel, which renders any operation very difficult and pregnant with risk to the patient. I have experienced a case of this kind in treating a carcinoma of the cervix, when I had to risk the evil to combat the growth. Relative contraindications are patients bled white through loss of blood, where the red blood count is reduced by one-half, the leucocytes increased by one-half, and pulse and temperature warn us that the patient is at a low ebb. In these cases I always keep the patient in bed for two to three weeks on a free diet, injections of iron, sodium cacodylate, and large quantities of lemon water to drink.

Causes of Bleeding some Months after Amenorrhoea.

Chief among the causes of late recurrence are: (1) septic foci, pyorrhoea, etc.; (2) cystic ovaries; (3) pelvic inflammation; (4) high blood pressure associated with contracted kidneys.

Recurrence of symptoms at a late period (a year and more) at the menopausal age was found in 7 cases. One of these occurred two years after amenorrhoea was established, and took the form of a blood-stained discharge; examination showed the cervix to be normal and the body of usual size. Some carious stumps with pyorrhoea were found on routine examination; the former were removed, and the discharge disappeared with a simple douche. Two more cases were associated with pyorrhoea, and the haemorrhage ceased after removal of the teeth. In two other cases the recurrence was associated with chronic nephritis and increased blood pressure. Two were associated with ovaries which had become enlarged and cystic. Apart from these cases there was no recurrence. Two of this group had been treated with two exposures to radium and one with three exposures.

Recurrence in patients between 30 and 40 years of age took place in 10 cases, in 5 of which radium had to be used a second time, but they were more a continuation of the

original haemorrhage than a recurrence. One, aged 35, had a recurrence after eight months and became normal; two (aged 32 and 37) after a year and became normal; one (aged 38) recurred after four months; and one (aged 39) after seven months.

THE IMPORTANCE OF BENCE-JONES ALBUMOSURIA IN DIAGNOSIS.

BY

ERNEST S. REYNOLDS, M.D.LOND., F.R.C.P.,

EMERITUS PROFESSOR OF CLINICAL MEDICINE IN THE UNIVERSITY OF MANCHESTER; CONSULTING PHYSICIAN TO THE MANCHESTER ROYAL INFIRMARY.

THE subject of Bence-Jones albumosuria is an old one, but from recent experience I am sure that it is by no means always recognized, nor is the importance of its presence sufficiently appreciated, not only as a diagnostic or even pathognomonic sign, but also as an indication of a serious condition of affairs in what may appear to be a simple and straightforward case. These points are illustrated by the three following cases I saw in 1925.

CASE I.

A man, aged 60, consulted me on February 20th, 1925. He said that six months previously he had pains over the left shoulder and down the arm, which gradually got worse and then slowly improved, but were still present. These were apparently due to an ordinary brachial neuritis affecting the fifth and sixth cervical roots. He then said that for three weeks he had had pains across the front of the upper abdomen, which he put down to dyspepsia. I found no abnormal physical signs anywhere (the spine being freely movable) except a small gland the size of a hazel-nut, just above the left clavicle; it was painless and indeed had not been noticed by the patient. On testing the urine as a mere matter of routine, I was surprised to find large quantities of Bence-Jones albumose present. I wrote to Dr. Walter Buck, who had recently seen the patient, and warned him that it might turn out that the pains were caused by a myeloma of the vertebrae. An x-ray photograph revealed nothing abnormal.

The pains got worse; a surgeon was consulted some weeks later, who thought there was some thickening in the lower cervical region. I saw him again at his home with Dr. Buck on May 2nd. His left arm was now partially paralysed, and the pains down the spine were intense. He afterwards had constant vomiting, intense pains in the head, and died of exhaustion in July last. Unfortunately no *post-mortem* examination was made.

CASE II.

A compositor, aged 49, was sent to see me by Dr. Baker of Preston on September 24th, 1925. In the previous April he had complained of pain in the left side of the chest, which was thought to be due to diaphragmatic pleurisy, but there were no physical signs. In August the pain got worse, and extended round from back to front on both sides in the area of distribution of the fifth to the seventh dorsal roots. A specimen of urine was sent to a pathological research laboratory, and the report was that the urine contained a trace of albumin and a "substance of a balsamic nature of uncertain origin." An x-ray report stated that disease of the fourth to the seventh dorsal vertebrae was present (? growth in the vertebral bodies or in the posterior mediastinum). There was a marked prominence of the fifth and sixth dorsal vertebral spines, and the pain in the back was very intense. On examination of the urine I found that the "substance of a balsamic nature" was an immense quantity of Bence-Jones albumose.

Dr. Baker kindly wrote to me on January 26th, 1926, stating that the patient has much improved as the result of deep x-ray therapy applied by Dr. Rayner of Preston, and with the assistance of a spinal support had been able to return to work, as the pain was so much less, but x-ray photographs show a rather more marked angular curvature, and the Bence-Jones albumosuria is still present.

CASE III.

On November 29th, 1925, I was asked by Dr. T. Gregory of Manchester to see a clerk, aged 19. He had been first seen by Dr. Gregory in October, 1924, suffering from rapid heart and dyspnoea, with no obvious cause. The symptoms continued, and in January, 1925, the suprascapular glands on both sides were found to be enlarged. In July the spleen was enlarged, as well as the left axillary glands, and in August occasional rises of evening temperature up to 100° F. began, with enlargement of the right axillary glands and pains in both iliac fossae and

over the sacrum. Bence-Jones albumose was found in the urine for fourteen days.

In September the albumosuria recurred occasionally, and he got rapidly worse, with much anaemia; the evening temperature sometimes reached 102° F. During November the albumosuria was present in increased amount, and the whole spine was found to be a uniform convex (backwards) curve from end to end; any movement caused intense pain in the spine and round the abdomen and chest, and sometimes in the arms and legs. The temperature rose irregularly each evening to 102° or 103° F., and he died on December 4th.

This was obviously not a case of pure myeloma, but rather one of acute lymphosarcoma affecting many parts, including the spine, or of acute Hodgkin's disease become malignant.

The presence of this peculiar albumose was first described by Bence-Jones in the *Philosophical Transactions* of the Royal Society in 1848 as found in the urine from a case said to be of "mollities ossium" [but much more probably of myeloma—E. S. R.]. As the reactions given are somewhat different from those of other albumoses found in the urine, it is always best to refer to this substance as "Bence-Jones albumose." Its source is probably the cells of the tumour. An excellent and full paper on the subject, containing a detailed description of the reactions obtainable, was written by Bradshaw in the *Transactions* of the Royal Medical and Chirurgical Society for 1898 and 1899; and another paper by Anders and Boston (based on three cases) was published in the *Lancet* in 1903.

Chemical Characters.

The essential reactions are as follows: On applying heat to the slightly acidulated urine a white precipitate occurs at a temperature of about 55° C. (132° F.). On further heating this precipitate dissolves, and reappears on cooling. It will, of course, be remembered that serum albumin is only precipitated at about 80° C. (176° F.), and does not disappear on further heating. Cold nitric acid causes a dense precipitate of Bence-Jones albumose, and this precipitate disappears on heating and reappears on cooling. Even when the urine is diluted with twenty times its volume of water hydrochloric acid causes a sharp white ring to appear at the place of contact, and this ring disappears on heating and reappears on cooling (albumin is only precipitated by hydrochloric acid in excess).

Now in ordinary clinical work most of us do not use thermometers when testing urine by heat, nor we do as a rule use hydrochloric acid. So I wish to point out a very easy observation which will infallibly indicate Bence-Jones albumose. Take about 4 inches of urine (slightly acidulated if necessary with acetic acid) in a test tube, and apply heat gently to the top inch. If Bence-Jones albumose is present it is astonishing to note how soon a precipitate forms, and how this precipitate, which is at first of a particularly fine grain, spreads rapidly down the urine. On further heating this fine precipitate dissolves; but in my experience not by any means entirely, as much of it clings together in thick masses, sticking to the side of the test tube. If the cold nitric acid test is now tried, by pouring the acid very gently down an inclined test tube containing the urine, a dense precipitate will form at the place of contact, and this will rapidly spread up the urine as a fine-grain precipitate. These simple experiences are entirely different from those obtained with an ordinary albuminous urine, and once seen are never forgotten.

It is, of course, principally in cases of myeloma that Bence-Jones albumose is formed. The myeloma itself may not be evident, as it may occur in the vertebrae and it may not be discernible by x rays; moreover, the only symptoms may be definite root pains, such as occur in an ordinary local neuritis, or there may be vague pains relating to the vertebral column; in such cases the presence of Bence-Jones albumosuria at once indicates the seriousness of what at first sight appears to be a slight illness.

This condition is supposed to be very rare; but I can recall five other cases I have seen in hospital or in consultation within recent years, in addition to the three cases mentioned above. I am therefore inclined to think they are commoner than is usually supposed, but that they are not always recognized (even in pathological research laboratories), and for that reason I have written this note to revive some old knowledge.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

FLOATING APPENDIX.

DURING the last few years I have operated upon three cases of appendicitis, the pathology of which I have not seen described, though the symptoms are very characteristic of the condition.

The patient complains of a very acute pain in the abdomen, not specially located to the right iliac region; in two of the cases there was vomiting. Seen shortly afterwards one finds a board-like condition of the whole of the abdomen; there is perhaps more pain on palpation towards the appendix region, but the noticeable point is the extremely marked rigidity. The temperature and pulse rate are slightly raised, or may be unaffected. The patient's appearance is not that of anxiety, or of being very ill, such as is expected in a case of ruptured viscus, nor is there any sign of collapse.

Operation.—On opening the abdomen the appendix is seen to be quite free, erected and of a vividly scarlet colour, especially towards the tip; there is no sloughing. In the peritoneal cavity is some clear odourless fluid and some congestion of the surrounding peritoneum, but no adhesions of any kind, nor any plastic lymph.

Case I was in hospital; it was cleanly sewn up, and made a good recovery.

Case II was in a nursing home. As there was much clear fluid a tube was put in for drainage; general peritonitis supervened, and the patient became gravely ill. As there was no smell or faecal odour I thought the condition might be pneumococcal, and gave three injections of pneumococcus vaccine; six days later an abscess developed in the left iliac region, which I opened; it was found to be between coils of small intestine. The patient made a good recovery.

Case III occurred in hospital recently; it was cleanly sewn up, and recovery was uneventful.

The last case was diagnosed as a floating appendix, from (1) the board-like condition of the whole of the abdomen, which had been observed in the former two cases; (2) the patient did not look ill, compared with what one would expect with such rigidity; (3) there was no collapse to suggest ruptured duodenum or stomach; (4) the patient lay placid with no complaint of pain after the first sudden onset.

Unfortunately I omitted to take a swab in any of the cases, and I am anxious to know whether any surgeon with more experience can identify this condition of appendix, and give an explanation of the causation—that is, whether it is due to any specific organism (the pneumococcus, for example).

C. L. GRANVILLE CHAPMAN, F.R.C.S.Ire.,
Surgeon, Grimsby and District Hospital.

RAW PANCREAS IN DIABETES MELLITUS.

THE following case, which was under the treatment of Dr. C. Vosper in the Kashmir Mission Hospital, illustrates the value of raw pancreas in some cases of diabetes mellitus.

A Mohammedan lad, aged 16, was admitted on March 9th, 1925, with polyuria and progressive emaciation. The urine showed 12 per cent. sugar. He was put on Allen's treatment, with a weekly fast, and the sugar came down to 4 per cent. Insulin was then commenced. As we had no facilities for estimating blood sugar, the initial dose given was 5 units; this was increased on the fifth day to 10 units. During the first fortnight of April the sugar averaged 8 per cent. The insulin was increased to 15 units on April 14th. But the sugar still fluctuated between 4 and 12 per cent. We then stopped the insulin and resolved to try raw pancreas. There was no definite improvement, but I found that what was being given was not pancreas. Fresh orders were issued and minced raw pancreas administered—2 to 3 oz. daily. On April 20th the sugar was 6 per cent., on April 21st 4 per cent., on April 22nd 2 per cent.; on April 23rd there was no sugar and the urine remained free while the pancreas was being administered. The patient left hospital on May 28th much improved.

The question of the relation of insulin treatment to that by raw pancreas is interesting. Hollins considers that raw pancreas is ineffective when given after, or at the same time as, insulin. This case does not support this view. In Harrison's case a patient with a constant administration of 60 grams of carbohydrate, 70 grams of protein, and 150 grams of fat, and who took 20 units of insulin before breakfast and 14 before tea, over a period of six months,

maintained a fairly level blood sugar percentage. He was then also given 2 oz. of raw pancreas daily. There was no further reduction of blood sugar, so Harrison concluded that the pancreas was inert. He repeated the experiment in a child aged 4, with a similar negative result, and is therefore inclined to discount the value of pancreas. George Graham appears to support Harrison and considers raw pancreas inert. In the case recorded above we administered insulin in small doses, with but little effect. The introduction of pancreas was decisive.

The cases published by Drs. Constance Griffiths, W. Dunn, Robertson Young, Helena P. Kelly, and T. J. Hollins strongly support the view that raw pancreas may be of real value in the treatment of diabetes. Its failure in some cases, whether used alone or in association with insulin, calls for further investigation, but in no way negatives its use in other cases.

ERNEST F. NEVE, M.D., F.R.C.S.E.,
Senior Surgeon, Kashmir Mission Hospital.

ROUND-CELLED SARCOMA OF PANCREAS IN AN INFANT.

THE following case seems to me sufficiently uncommon and of interest from the *post-mortem* findings to be worth noting.

A female infant, one of twins, at the age of 6 months commenced to vomit occasionally and pass undigested fatty loose stools. The abdomen became distended, with slight dullness in the flanks. Later she had, from time to time, oedema of the eyelids (without relation to crying) and of the feet. She cried a good deal and appeared at times in pain. She became emaciated; her weight varied according to the oedema and abdominal distension, the circumference of the abdomen varying from 14 to 17 inches.

The urine contained no albumin or sugar. Several foods were tried, but certified cow's milk and water suited the child best.

The vomiting increased, but, on reducing the fat in the feeding, both the vomiting and the fatty character of the stools improved for a time. The child became more emaciated and less able to digest its food, even vomiting albumin water. On palpation of the abdomen no tumour could be felt. Death occurred at the age of 11 months.

At the *post-mortem* examination a growth $2\frac{1}{2}$ inches square by 1 inch in thickness, which proved to be a round-celled sarcoma, was found growing from the posterior surface of the pancreas. There was free fluid in the peritoneal cavity. The other organs were healthy.

A. DEANE, M.D., Ch.B.,
Honorary Surgeon, Princess Alice Hospital, Eastbourne.

AN UNUSUAL PRESENTATION.

THE following details of a rare case of compound presentation, resulting in the birth of a live child, seem to be worthy of record.

A woman, aged 42, who had had fourteen children after normal labours and one miscarriage, was admitted to hospital in the early morning of December 23rd, at the thirty-second week of pregnancy. The membranes had ruptured spontaneously, but there had been no labour pains. The os was the size of a florin, and two feet could be felt presenting, though rather high up. No foetal heart could be heard, and on examination there was great doubt as to the position of the head of the foetus. A diagnosis of breech presentation was made. In spite of treatment with castor oil, quinine, and an enema, no definite labour pains commenced till 3 a.m. on December 27th, when strong and regular pains began. At 6.35 a.m. the os was fully dilated, and a few minutes later the foetus was born spontaneously. The head, feet, and legs were born together, the foetus being doubled on itself and the head being in the left occipito-posterior position. The feet were in advance of the head, and the antero-medial aspect of the tibiae rested against the left frontal bone, deeply grooving the forehead; the tibiae showed marks of pressure for several days. The child weighed 5 lb. 6 oz., and was thriving when the patient was discharged from hospital. There was no perineal tear and no delay in the second stage.

D. J. MALAN, M.D.,
Obstetric Tutor, London Hospital.

PREGNANCY IN DOUBLE UTERUS.

THE following case is, I think, of sufficient interest to be placed on record.

A married woman, aged 25, British, consulted me on account of dysmenorrhoea and menorrhagia from which she had suffered since the age of 14. The periods started at that age, and had always been irregular, coming at intervals of from two to three weeks. They usually lasted for about a week, and during that time she suffered from headaches, backaches, and often faintness. She had been married for nine months. I found the vagina to be divided by a fleshy septum running antero-posteriorly and

extending for the whole length of the vagina, which was about 5 inches. The clitoris and labia were normal. A separate cervix could be felt protruding into each division of the vagina. On examination under an anaesthetic the condition was found to be that of complete double uterus (uterus didelphys). The cervixes were quite separate, but the bodies of the uteri were fused together. The length of these uteri felt to be about 1½ inches. A sound could be passed into each uterus for a distance of 1 inch. She missed the next period after the examination, and in three months it was obvious that she was pregnant in the right uterus.

The cervix of the right uterus softened, whereas that of the left remained hard. During the earlier months of pregnancy the enlargement was felt mostly on the right side of the abdomen, but during the later months it occupied a more central position. The patient suffered from slight morning sickness during the second month. Apart from that she was very well, and complained of no discomfort. The pregnancy pursued a normal course, but there was a breech presentation of the foetus. This was probably due to the fact that the left uterus had enlarged, pressing on and restricting the space in the lower pole of the right uterus. It was found impossible to change the presentation by version. The pelvic measurements were: interspinous diameter 8½ inches, intercrural diameter 9½ inches, external conjugate 6½ inches.

On account of the small pelvic measurements, the persistent malposition of the foetus, and the malformation of the vagina, I decided to perform Caesarean section a week before time. I delivered a normal female child of 6½ lb. On opening the abdomen the pregnant uterus was seen to be pear-shaped, with the largest diameter at the fundus. The left uterus, enlarged to a length of about 6 inches, was pressing on the lower uterine segment of the pregnant uterus. The ovaries and tubes were normal. The placenta was situated on the posterior wall of the uterus rather low down. The mother made an uninterrupted recovery and was able to feed her child. Three days after the extraction of the child a decidua, 5 inches in length, in the form of a perfect cast of the uterine cavity, came away from the left uterus.

This remarkable case was also seen by Drs. G. E. Aubrey and J. W. Anderson.

J. C. MacGown, M.B., Ch.B. Edin.

Hong-Kong, China.

British Medical Association.

CLINICAL AND SCIENTIFIC PROCEEDINGS.

MONMOUTHSHIRE DIVISION.

A MEETING of the Monmouthshire Division of the British Medical Association was held at the County Hall, Newport, on February 26th, with Dr. D. ROCYN-JONES, C.B.E., in the chair.

Puerperal Mortality.

The Chairman intimated that the meeting had been called to consider the questionnaire issued by the British Medical Association in relation to the contemplated report on the causation of puerperal morbidity and mortality, and they were fortunate that afternoon in securing a visit by Sir Ewen J. Maclean, professor of obstetrics and gynaecology at the Welsh National School of Medicine, Cardiff, to address them upon puerperal mortality. On behalf of the Division he extended a most hearty welcome to Sir Ewen to address the meeting.

Sir EWEN MACLEAN then delivered the address which is published in full at page 469. A discussion followed upon the address and upon the questionnaire of the Association, in which the following members took part: The Chairman, Sir Ewen Maclean, Dr. Hamilton, Dr. Sullivan, Dr. Noel Wade, Dr. Catto, Dr. Candy, Dr. Rufus Thomas, Dr. Frost, Dr. Griffiths, Dr. Donaghy, Dr. Verity, Dr. James, and Dr. Morrell Thomas.

Dr. RUFUS THOMAS gave his views upon infantile morbidity and mortality in individual practices. He had kept a record of the last 150 pregnancies, and the results as far as infantile mortality was concerned were as follows: 144 pregnancies terminated between seven months and full term. The remaining 6 cases were abortions, 5 being in the third month, and 1 in the fifth month, in which labour was induced from pernicious vomiting. Two cases had placenta retained and were running temperatures, which subsided as soon as the uterus was cleared out. The case of pernicious vomiting ran a temperature for two days after delivery, but it subsided of its own accord; 148 babies were born, there being four lots of twins. Of these 148 babies, 10 were born dead or died within forty-eight hours;

5 of these were born dead, all the mothers having albuminuria, pre-eclamptic or eclamptic. One died of convulsions forty-eight hours after birth, this mother also having albuminuria and eclampsia. In regard to Question 9, it was certainly Dr. Thomas's experience that operative intervention was very frequently asked for, either by the patient, her relatives, or the nurse, and more particularly in the case of first labours, which were those requiring much longer time for dilatation, and therefore the very ones in which intervention should be postponed to the last moment, commensurate with safety to mother and child. The difficulty of resisting these requests for too early intervention was often very great.

Dr. ROCYN-JONES drew attention to the serious discrepancy which existed in the administrative county of Monmouth between the notification of puerperal fever cases and the registration of deaths occurring from puerperal fever, and gave the following statistics:

Maternal Mortality in the County of Monmouth, 1915 to 1924.

Year.	No. of Cases of Puerperal Fever Notified by District Medical Officers.	No. of Deaths Registered.			Death Rate per 1,000 Births.			Infantile Death Rate per 1,000 Births.
		Puerperal Fever.	Other Diseases or Accidents of Pregnancy.	Total.	Puerperal Fever.	Other Diseases or Accidents of Pregnancy.	Total.	
1915	22	10	44	54	1.0	4.7	5.7	128.5
1916	14	8	33	41	0.91	3.69	4.6	83.4
1917	4	9	30	39	1.07	3.53	4.6	84.3
1918	6	6	26	32	0.65	2.84	3.5	97.6
1919	19	11	36	47	1.29	4.24	5.53	88.0
1920	24	20	42	62	1.85	3.9	5.75	87.9
1921	17	13	29	42	1.26	2.81	4.07	91.5
1922	11	14	33	47	1.6	3.73	5.33	83.4
1923	19	9	29	38	1.03	3.31	4.34	73.0
1924	15	10	23	33	1.19	2.75	5.94	75.6

It should, he said, be noted that the number of cases of puerperal fever notified was not a true record of the total cases which occurred. Many of the deaths registered as due to puerperal fever had not been notified under the Notification of Infectious Diseases Regulations.

Dr. CANDY gave his experience of x-ray work in pregnancy, and drew the attention of the meeting to a new development which he thought had some bearing on the subject under discussion—namely, the recent advance in radiological technique which rendered x-ray examination of the foetus *in utero* a successful and safe procedure. By the aid of x rays the obstetrician could now obtain information of the utmost importance concerning the course of pregnancy which he could not obtain with certainty by any other means. He could thus be forewarned against difficulties and be prepared to deal with them. Not only would it enable the practitioner to approach a case with less anxiety and help to reduce the mortality rate, but also by the routine x-ray examination of all cases in maternity hospitals and ante-natal clinics much new knowledge would be gained concerning the physiology of normal pregnancy. In this way Röntgen's discovery might eventually prove as great an influence in the advancement of the art of obstetrics as, in the past quarter of a century, it had been in the advancement of surgery. Though the possibilities of x rays in obstetrics were far-reaching, he regretted to say that, so far, they had been little explored in this country. He thought that this was due to lack of information among the profession generally upon the subject, and he felt the occasion was not inopportune to draw attention to it.

The meeting tendered a unanimous resolution of thanks to Sir Ewen Maclean for his admirable address and for his visit, the resolution being moved by the CHAIRMAN, seconded by Dr. HAMILTON, and supported by Dr. MORRELL THOMAS. Sir EWEN MACLEAN briefly responded.

Reports of Societies.

IODINE THERAPY IN EXOPHTHALMIC GOITRE.

SEVERAL Sections of the Royal Society of Medicine combined on March 3rd for a discussion on exophthalmic goitre. The subject on this occasion was considered solely from the point of view of iodine therapy, leaving for another evening a discussion of the general management and indications for operation. Dr. GEORGE GRAHAM, President of the Section of Therapeutics and Pharmacology, was in the chair.

Professor E. MELLANBY, in opening, said that it was a strange thing that a discussion on the treatment of exophthalmic goitre should be initiated by a consideration of the action of iodine in this condition, because, in the previous discussion in the Society in 1921, iodine was quite unmentioned. It was known at that time that iodine had a profound influence in exophthalmic goitre, but it was also recognized that it could do a great deal of harm, and therefore it was left out of account. But if a substance was to be completely rejected as a therapeutic agent because it did harm, then the sooner they all became homoeopaths the better. Practically every drug used—mercury, digitalis, ipecacuanha, for example—could do a great deal of harm. It was necessary in using any drug to have regard to the conditions under which it could produce baneful effects. From a laboratory point of view it might be expected that iodine would have a profound influence on exophthalmic goitre. He showed lantern views of the thyroids of dogs which had been on experimental diets. The only difference in the diet as between two series of dogs was that the one had had cod-liver oil, which contained a quantity of iodine, and the other had had butter. In the former the glands were small, in the latter greatly enlarged. A gland from one dog which had been denied iodine weighed forty-four times as much as that from a dog which received this substance in its diet. Moreover, iodine had a profound influence in regulating not only the size but also the structure of this gland. Clinically, iodine in hyperthyroidism brought about some significant changes; in the course of a few days the heart was made to beat much more slowly, sweating was greatly reduced, tremors were also reduced or disappeared, and the patient, from being restless and semi-demented, became placid and almost normal. Iodine affected not only the pulse rate but also the whole metabolism. The basal metabolism was greatly reduced after the administration of iodine, but it tended to rise again, though not to the previous level, and the symptoms might return. On cutting off the iodine, no matter how long it had been continued, the symptoms recurred with some severity, and if the iodine treatment was then resumed the relief, although notable, was not so great as at first. That was the usual effect of this treatment in exophthalmic goitre, but in some cases there was a different result. The first action of the iodine in relieving the symptoms was followed in these cases by a very sudden and acute exacerbation, although the iodine was being given all the time. There was a recovery from this exacerbation in the course of a few days, only to be followed by a second exacerbation, and so forth. The cases in which this contrary result was found were described as cases of toxic adenoma, or, to adopt Williamson's new nomenclature, secondary Graves's disease. They were people who had had large thyroids, often for a long time, without symptoms, and then developed symptoms; the glands were hard and "nobbly," as well as large. Professor Mellanby, after showing the charts of some cases, discussed the advantages and disadvantages of iodine therapy. The advantages were the very rapid disappearance of symptoms—not only, of course, a good thing in itself, but also valuable as a preparation for surgery; an improvement in the condition of the patient during the whole of the time that the iodine was administered, and in some cases a complete recovery. As to these last cases, he admitted that it was quite possible that many of these people might have recovered without iodine,

but, on the other hand, he had a very strong feeling that iodine had played a part in the recovery. The disadvantages were that in some cases, more particularly cases of secondary Graves's disease, there were certain definite dangers from the sudden exacerbation of symptoms; that in "normal" cases, whenever the treatment was stopped, there was exacerbation; and that with iodine treatment there was a possibility of getting asphyxiation—that is, if there were any pressure symptoms in the first place, these would almost certainly be made worse by this form of treatment. In addition to giving iodine in these cases, he tried to regulate the diet to some extent. The diet included all the ordinary foodstuffs, with plenty of milk, but he tried to keep the caloric value of the diet low, because he had found in animals that the more food they were given the bigger did the gland become. Altogether, while fully alive to the disadvantages and dangers of iodine treatment in certain exceptional cases, he regarded it as a valuable adjunct in dealing with exophthalmic goitre.

Dr. J. W. McNEE thought that in cases being prepared for operation iodine treatment was of great importance. *The correct time for the operation to be undertaken after the administration of iodine was begun* was now quite well recognized—somewhere about ten or twelve days—and the period could only be gauged by paying attention to the pulse rate, without even the need of basal metabolism determinations, although naturally these were of use. It had been stated that a fall in the pulse rate and a general improvement of the patient could be attained by rest in bed alone. This was not so. Frequently the pulse rate could be reduced, and a certain improvement brought about in that way, but on giving iodine the pulse rate fell considerably more, and the improvement was much greater. After ten or twelve days' iodine treatment he believed that the operative risk was much lessened, and he believed also that surgeons could remove with greater safety than before a much larger part of the thyroid gland. He had been struck with the frequency of a return of symptoms in cases in which a hemithyroidectomy had been done. During the last few months he had seen four such cases, in one of which the operation took place six years ago, and in the others three or more years ago. In all these cases there was a great exacerbation of symptoms, with much enlargement of the other lobe, and second operations were required. Although the optimum period for operation appeared to lie between the tenth and the fourteenth day after iodine had been commenced, even after this period, although the pulse rate might rise again, the symptoms were never so severe, and his surgical colleagues told him that they felt perfectly safe in operating even after the optimum period had elapsed. He desired also to say a word about the use of iodine in the control of the so-called crises in exophthalmic goitre. He had not seen in this country crises anything like the astonishing exacerbations that he had seen in America, especially during a visit to the Mayo Clinic, where there were cases from the Mississippi valley, a region in which exophthalmic goitre was notoriously severe. There he saw patients with such pronounced exophthalmos that the eyes lay right out on the cheeks, and the patients were really acutely insane. Crises less severe were seen in this country, and in these the effect of iodine in restoring tranquillity and mental alertness was quite astonishing. Another point was the treatment of cardiac failure in Graves's disease. He had had the opportunity of trying iodine in two cases of cardiac failure, and even with large doses he obtained no effect at all. The usual effect was obtained with digitalis, but with iodine not the slightest. So far he had not had a chance of treating cases with iodine medically over a very long period of time. In the bulk of his cases iodine had been given with the deliberate intention of preparing for operative intervention, but so far as his experience of medical treatment with iodine had gone he could not say that he had been impressed with the results.

Dr. GUSTAVE MOXOD described the case of a female patient, aged 45, who was admitted to a hospital in Paris with most definite symptoms of Graves's disease. The basal metabolism was greatly increased. The patient

was submitted to x-ray treatment with no result. She then developed glycosuria, and insulin was administered in large doses. As might be expected, the diabetic symptoms cleared up immediately, but there was great improvement in the exophthalmic goitre symptoms also, which went on to perfect cure. Unfortunately the patient a few months later developed pneumonia and died. Exophthalmic goitre cases were highly tolerant of insulin.

Professor F. R. FRASER said that at his hospital during the last five years fifty cases of exophthalmic goitre had been treated with iodine. At the beginning of that period he and those working with him had no idea what dosage ought to be given, so that harm was done in a certain number of the cases. Doses were tried of 30 minims of 10 per cent. solution of iodine in alcohol a day, and this was increased in some cases to 60 minims and above. The result in some cases was an immediate remission, but with the very large doses harm was done. In some cases a great enlargement and hardening of the thyroid gland was produced, with much increase of tachycardia and palpitation and a sensation of choking. They had now learned that they could get good results with much smaller doses. The preparation used mainly at present was a 10 per cent. solution in 95 per cent. alcohol. There was some danger in prescribing tincture of iodine, which contained a great deal of iodide as well as iodine, and great care was necessary when using the word "tincture" as to the proportion actually employed. The general practice of himself and his colleagues was to keep the patient in bed for some time, to commence on 5 minims of the alcoholic solution three times a day, then, when a maximum result had been attained, to reduce it to 5 minims twice a day, and before the patient left the hospital to bring it down to 5 minims once a day; the patient was never sent out on a larger dose than that. Even with this careful cutting down of the doses it was found that occasionally harm was done if a very close watch was not maintained, and the cases in which this harm was done were those which had been described as secondary Graves's disease. Cases in which there were symptoms of intoxication with a thyroid already damaged, or in which there had been a simple goitre for many years beforehand, did not tolerate iodine in the same way as the others. The dramatic results obtainable in the other cases were not forthcoming here, and, in some, definite harm might be done. In such cases the dose was brought lower still, sometimes to 2 minims a day. He believed that every case of thyroid intoxication could be benefited if only the right dose were found to suit the patient. Dr. McNea had spoken about cases with circulatory failure not responding well to iodine; that also was his experience. These cases again were almost always of the secondary Graves's disease type. He had some cases which had been on iodine for four years, not quite continuously, for every now and then the administration had been stopped for a few weeks, and in every case the patient, returning after that interval, had asked to be put back on iodine. As for results, he had no doubt that by means of iodine carefully adjusted in the way described the disease ran its course at a lower level of intoxication. If the disease was going to recover spontaneously it did so recover, having run a milder course. The effect of iodine in preparing a patient for surgery was most valuable. There were a great many derelicts in exophthalmic goitre, no matter what medical measures were used; these derelicts required surgery, and by means of iodine the operation could be made much safer. After operation iodine over a prolonged period of time had a distinct value. Many of the operated patients declared that while they were improved after the operation they began to improve much faster once iodine was recommenced. Iodine, however, would not "hold" a case against such crises as tonsillitis, or emotion and excitement due to domestic worry. In conclusion he hoped that no one would think that iodine therapy in exophthalmic goitre was a simple and easy treatment. It must be used with the patient under daily observation, the dose carefully regulated with the patient in bed, and if the patient was allowed to take iodine without supervision he must first have been carefully studied to learn exactly how much he could take and how he reacted to it.

Mr. T. P. DUNHILL said that the operation for exophthalmic goitre should never be an operation of emergency; the patient must be brought into a proper condition before it was attempted. Cases that had come to hospital for operation had been made enormously better by treatment by this method. After the patient had been in hospital for a little while the pulse dropped to some extent, but if, after the greatest drop that could be obtained by rest, iodine in the appropriate dose was administered, the patient began to look and feel better and the metabolic rate was lowered. When the operation was performed it was undoubtedly fraught with less risk and the patient lost less blood. Many of the troubles associated with operation for exophthalmic goitre were due to the amount of blood lost at the operation. After iodine treatment the gland was smaller, harder, and definitely less vascular. The gland felt almost like a piece of brick when handled, and in freeing the outer margin, if care was not taken, the trachea was rotated and the patient felt pressure; it was also easy, again, unless great care was taken, to encroach on the region of the laryngeal nerve. He thought it might be possible for surgeons to remove less of the substance of the gland than they had been in the habit of doing, and for the patient, with the help of iodine, to be restored to normal. He could not help thinking that operation in exophthalmic goitre was in any case a temporary expedient, and not an ideal to be striven after. He went on to point out a striking difference between the primary and secondary types of goitre in respect of the great amount of fibrosis in the latter. In the secondary type the channels of communication were interfered with. If the secretions from the gland were shut up in that way the effect of iodine on the gland cells and units could not be quite the same as in a thyroid in which the channels were quite freely communicating with one another. Before iodine was given the patients should be got into bed, and kept under close observation.

Dr. J. A. RYLE said that he had not enough experience of iodine therapy to speak critically, but he was an opponent of any overzealous attempt to find a specific method of therapy for a disease which was essentially non-specific. It was exceedingly difficult to draw conclusions about the effect of any line of treatment, even in the case of a disease due to some specific germ, and in the case of a non-specific disease like exophthalmic goitre much more difficult. Extraordinarily little was known about the cause and pathology of this disease; probably several factors were at work—physical, metabolic, infective, and, in almost every case, a strong emotional factor. If that emotional factor were predominant it was necessary to be very careful before seeking a chemical answer to the problem or treating it by a physical means like operation. The essential preliminary to any treatment was a familiarity with the natural history of the disease. The results of an investigation into the natural history of exophthalmic goitre were recorded in the *Archives of Internal Medicine* in 1923, and seemed to bear out the wisdom of treating these cases with "skilful neglect." The patients were placed in good surroundings, in a ward with a cheerful sister, and the only special treatment was the removal of obvious focal sepsis. Out of 50 such patients, 41 returned to their ordinary life socially and economically restored. It was necessary to be more familiar with the psychological aspects of this disease, and there was real danger in disseminating observations about such ultra-specific methods of treatment as iodine and surgery. Iodine played only a very small part in treatment; it was valuable as a preparation for surgery, and had a more limited value as an aid to medical treatment, but personally he would prefer to treat a case with optimism rather than with iodine.

Dr. H. E. B. CALVERT said that if iodine were pushed so as to make the thyroid gland stony hard the best results were not obtained. It was desirable to make the gland just firm. This disease was not primarily thyrogenic; it was a reaction to some metabolic disorder. He gave an account of two remarkable cases which had improved under iodine treatment.

The CHAIRMAN commented on the difference in dosage of iodine, and pleaded for some standard prescription. Professor MELLANBY, in replying to the discussion, spoke

of the unanimity among workers who had been using this form of treatment under as nearly scientific conditions as it was possible to obtain clinically. The only critic was Dr. Ryle, whose remarks had been academic rather than based on experience.

ANAESTHESIA AND DISORDERS OF THE CIRCULATION.

At a meeting of the Section of Anaesthetics of the Royal Society of Medicine on March 5th Dr. C. E. LAKIN read a paper entitled "Anaesthesia in relation to disorders of the circulation."

Dr. Lakin said he would not touch on the subject of Graves's disease, which had been discussed at a recent meeting, nor deal with spinal anaesthesia in cardiac cases, as his experience of this form of anaesthesia was too little to enable him to draw any conclusions. He would confine his remarks to general anaesthesia in cardiac disorders. Definite signs of myocardial degeneration were frequently found *post mortem* in patients who had had no obvious lack of cardiac compensation during life. People suffering from valvular disease rarely succumbed during anaesthesia. The important points for the anaesthetist were alterations in the character and rhythm of the heart sounds. A healthy first sound was low-pitched, dull, and booming, whereas in the diseased heart it was short and higher-pitched and resembled more the second sound of the normal heart. In advanced myocarditis the rhythm resembled that of a ticking watch. When the sounds were sharp, short, and weak, the muscular power of the heart was in abeyance owing to lack of tone, and this might be due to myocardial degeneration or merely to anaemia. In the middle-aged, if there was a tick-tack rhythm, low blood pressure, and a 1:1 ratio with the differential stethoscope, a condition unduly prone to ventricular fibrillation was present. Chloroform was often fatal in such cases. From experience in the *post-mortem* room the speaker was inclined to doubt the dictum that the healthy heart was more prone to disaster with this drug than was the diseased, and again, prolonged anaesthesia with chloroform produced a toxic condition more likely to prove fatal to the diseased than to the healthy heart. A tick-tack rhythm with shortened first sound was not always of serious import, for it was frequently found in anaemic women who reacted quite well to anaesthetics. In the acute rheumatism of childhood, especially when the first sound was almost inaudible, the administration of an anaesthetic was a serious matter. The condition of pulsus alternans, where every alternate beat was smaller than the one preceding it, was usually indicative of severe myocardial degeneration. This condition should not be confused with pulsus bigeminus, which was due to irritability of the myocardium and was not necessarily of serious import. Although pulsus bigeminus was frequently due to an extra-systole replacing each third rhythmic beat (the extra-systole being appreciable at the apex, though it did not reach the wrist), yet it was sometimes attributable to heart-block, each third ventricular contraction being lost. Such cases should be further investigated, since heart-block was an expression of myocardial degeneration. Epileptiform seizures, the so-called Stokes-Adams syndrome, might be present. Chloroform was, then, not the anaesthetic of choice. A slow pulse did not necessarily mean heart-block. Exercise had no influence on the pulse rate in heart-block. The slow pulse of the athlete might be recognized by the fact that with exercise it did not become faster by degrees as did the pulse of the normal person, but was quickly doubled in rate. Children showing sinus arrhythmia behaved to anaesthetics exactly as did normal children. Extra-systoles had no anaesthetic significance if they were the only phenomena found on examination. If, however, they occurred with other signs of myocardial disease, their significance was much more serious. Atrial fibrillation was evidence of cardiac failure. Rest in bed for ten days or more with the exhibition of digitalis might allow of an anaesthetic being given ultimately, as was also the case with pulsus alternans. In either case only operations of the utmost urgency should be undertaken

without preliminary treatment by rest. There were certain simple tests of cardio-vascular disability which should be practised by the anaesthetist. The patient should take a deep breath and hold it; if he was unable to do this for thirty seconds it was probable that he had some cardio-vascular defect. The effect of exercise on pulse rate and pulse pressure should be watched, the latter being the difference between systolic and diastolic pressure. In cardiac cases the systolic pressure, and less commonly the diastolic pressure, might fall as the result of exercise, the pulse pressure thus falling instead of rising. Blood pressure should be taken first with the patient lying down and then compared with the pressure sitting up. In myocardial disease there might be a higher blood pressure lying down than standing up. If these simple tests showed any abnormal results further tests with x rays, the electrocardiograph, and the polygraph should be made. Systolic and diastolic observations should be undertaken in cases of high blood pressure. If the diastolic pressure was only in the region of 90 mm. of mercury and no obvious arterio-sclerosis was present, it was possible to reduce the systolic pressure by 15 to 20 mm. in a week if the patient was put to bed and given daily salines with iodides; an anaesthetic might then be safely administered. If, however, the diastolic pressure was also high it was significant of increased peripheral resistance due to arterio-sclerosis, and an anaesthetic might be dangerous. Anaesthetics such as ether and nitrous oxide and oxygen, which tended to raise the blood pressure, should be avoided. If in addition to arterio-sclerosis there was renal disease, it meant that the end-products of nitrogenous metabolism were being retained, and uraemic coma might supervene upon anaesthesia. It should be remembered that people with a low blood pressure were liable to be much upset by morphine.

Dr. J. BLUMFIELD doubted the efficacy of morphine as a sedative in nervous cases; if a sedative was required, he preferred to give a fairly large dose of scopolamine. He also related the successful administration of an anaesthetic to a patient with heart-block, against the advice of the physicians.

Dr. A. L. FLEMMING also condemned morphine, and inquired if there was any danger in putting myocardial cases in the Trendelenburg position. He also wished to know whether it was justifiable to bleed patients with high blood pressure where the operation was urgent and there was no time for other treatment.

Dr. F. E. SHIPWAY deplored the fact that it was so seldom that the opinion of the physician was helpful to the anaesthetist. He also insisted on the necessity of maintaining an absolutely free airway in the case of myocardial disease. The Trendelenburg position often caused cessation of breathing in the case of old men suffering from renal and bladder diseases. In cases of high blood pressure he had found chloroform essential and morphine invaluable, especially if combined with scopolamine. In cases of aneurysm he preferred ether per rectum, together with morphine and hyoscine. Ether with oxygen was often quite suitable, especially if the induction was made with a chloroform-ether mixture.

Dr. HUGH PHILLIPS reported the case of a patient who took the anaesthetic quite well, but had since been hiccupping practically continuously; he was 67 years of age and very nervous, but his blood tension was only 140 mm., although he had a trace of albumin in the urine. The operation was for a new growth of the bowel, and Dr. Phillips asked whether the hiccupping was of cardiac origin.

Dr. H. P. CRAMPTON asked about the suitability of cases of paroxysmal tachycardia for anaesthetics, and Dr. R. E. APPERLY inquired whether preliminary doses of atropine had any effect on cardiac conditions.

Dr. LAKIN said, in reply, that the Trendelenburg position should be assumed very gradually in cardiac cases. Blood-letting was valuable in urgent cases with high blood pressure. Hiccup was not of cardiac, but probably of surgical origin. When paroxysmal tachycardia was present anaesthetics should be avoided if possible, as such cases were liable to cause trouble during anaesthesia. Atropine certainly had effects on cardiac cases.

AIRS, WATERS, AND PLACES.

At a meeting of the Section of Balneology and Climatology of the Royal Society of Medicine, held at 1, Wimpole Street, on March 4th, and presided over by Dr. C. W. BUCKLEY, Dr. F. G. CROOKSHANK read a paper on "Airs, waters, and places."

Dr. Crookshank said it would probably not be disputed by those interested in hydrology, balneology, climatology, and allied branches of medicine that two tendencies had lately become manifest at places where what was known as spa treatment was carried out. The first was the tendency to afford scientific explanations of the inexplicable, and the other the tendency to set up artificial substitutes for what was only successful when natural. In the textbooks written towards the end of the last century—in the days when it was thought the stethoscope and the *post-mortem* room, with the aid of the microscope, would teach all that it was necessary to know about life, death, and disease—spa treatment was mentioned only in terms of depreciation, with hints about a "pervading atmosphere of quackery" and gentle gibes about those who believed in the efficacy of the "water chemicals." Such scepticism was natural enough to physicians who really refused to believe what, as they said, they could not understand. It was, however, a fact that since the days to which he referred medical men, not content with observing the benefits accruing from spa treatment simply, naturally, and conscientiously carried out, had seemed to derive some kind of moral support from alleging those benefits to arise from radio-activity and what not, as if such alleged explanations made the matter any clearer! Those concerned were, indeed, no nearer the ultimate understanding of the curative processes initiated at Bath or Harrogate than they were a hundred years ago, when crude chemical analyses were first put forward as explanations.

In Dr. Crookshank's view the advantages derived from treatment or residence at any spa, in like manner to the physical or psychical conceptions of birth and life in particular regions, were not fairly to be attributed to any isolated factor, but were a function of the *milieu* in the sense of Auguste Comte: a function of a totality of exterior circumstances necessary to provoke the characteristic reaction on the part of the individual. The tyranny of the theorists who declared that only in the laboratory could experience be gained had lasted too long. Experience in the field was every whit as truly "experimental" as experience in the laboratory, and, for the physician and epidemiologist, more directly relevant. Indeed, if true progress was wished for there must be a return, sooner or later, to Hippocrates; and that a strong current of thought, avowedly based upon Hippocratic doctrines, had lately set in was illustrated by the school in France now engaged upon building up a new science of morphology which sought to observe man, not as a static thing, disjunctive to surroundings which compelled him to life or death as he was or was not fit to survive, but as constituting, with his surroundings, one definite continuity that exhibited a perpetual flux of adjustment and readjustment. The Hippocratic writer not only recognized the correlation between seasons and times and those disorders of adjustment to environment termed "being ill," but recognized a definite correlation between climates, the physical peculiarities of places, and types of mankind. Thus, in the quality of mineralization of the water and so of the food, both vegetable and animal, in special districts, was to be seen the explanation of the similar quality of mineralization, and so of physique of the inhabitants. That question was intimately linked with that of the endocrine glands and their influence on physique, for it was becoming more and more recognized that the activity of the thyroid was linked up with iodine in the food and drink, that of the parathyroid with calcium, and so on.

One of the advances of the future, Dr. Crookshank suggested, would be a recognition of the part played by minute traces of silicon, of fluorine, of arsenic, of copper, and of other minerals in food and drink in their relation with the activities of particular glands, and so forth, in the production of physical and perhaps racial types of varying kind. At any rate, it was becoming more and more

recognized that environment, while yet a unitary factor, was nevertheless of extreme complexity. But those questions were no less complicated than the epidemiological questions raised by the work *Airs, Waters, and Places*, and it would seem that in both respects it would be wiser to seek to balance the older empiricism with its synthetic judgements and simplified inductions rather than spend time and energy in a vain endeavour to isolate this or that specific factor or to secure victory for this or that theory. It might be said that Hippocrates did not in the work to which he had alluded make any express recommendations of a therapeutic order. Nevertheless, the therapeutic usage of airs, waters, and places, so far as it was rational, was a direct outcome of the Hippocratic study of the influence of *milieu* upon the health and character of the inhabitants, and it certainly involved a greater recognition of the thought of Lamarck than it was usual to accord in England. Those holding to the Lamarckian philosophy and the Hippocratic tradition might wonder whether the complexity of modern life and the luxuriant mechanisms of the present age were not co-operating to destroy what physicians would earnestly wish to conserve—the local characteristic and individuality of the environments to which they sent their patients. Local characters in respect of airs, waters, foods, habits, and so forth should be far more jealously guarded. It was idle to attempt to enlist Nature in a partnership in which the *raison d'être* was a sophistication of Nature's methods. He was not sure that even the spa physician himself was not more successful—in the right sense—when he was a native and an inhabitant, with local colour and local tradition, rather than a fashionable and fugitive visitor during the high season. At any rate, the closer the link between the physician and the locality the more valuable would be his contributions to epidemiology and to the knowledge of the play between airs, waters, and places and states of health and disease. There was more and more need for observation of such a nature as only the cultivated physician, attached to the soil and observant of Nature and Nature's methods, could give. The laboratory by itself was bound to fail. There was, however, no reason why investigations in the laboratory should not be prosecuted side by side with observation in the field of Nature—no reason except that when prosecuting observations in the field of Nature one could not be quite so confident of attaining ultimate explanations as could those who worked in the laboratory. And even if investigators were driven, like Hippocrates and Sydenham, to invoke "occult" and "hidden forces," it would not mean that there was a return to superstition and darkness. It would, on the contrary, indicate a more truly philosophic and scientific attitude than that taken by those who made glib use of the verbal "explanations" that passed current to-day, but which obscured rather than indicated the operations of Nature and man's reactions to Nature of which he formed part.

OBSCURE PYREXIA IN ADULTS.

At a meeting of the Medical Society of London on March 8th, the President, Sir HOLBURN WARING, in the chair, a discussion was held on obscure pyrexia in adults.

Sir THOMAS HORDER, opening the discussion, dealt with the subject from the point of view of a series of inquiries made by anyone faced with a case of obscure pyrexia. These inquiries or considerations came under the main headings of general and special. The first general consideration included the main causes of obscure pyrexia with few signs or symptoms. The essential cause in most cases was microbic, but there were certain other metabolic or nervous causes operating—for example, in Graves's disease, following severe muscular exercise, or in the curious "serum sickness" occurring seven days or so after the injection of horse serum. Certain exogenous foreign proteins also caused pyrexia, and there was no reason why endogenous protein bodies should not do the same. After a severe haemorrhage fever commonly followed and led to difficulties if infection were suspected. After a bout of haemorrhagic purpura, for example, fever frequently occurred, and also after post-partum haemorrhage pyrexia often led to difficulty. The nervous origin of pyrexia was important, there

probably being in certain cases an unstable thermotaxic centre. In these cases the underlying neurosis should receive careful treatment, and it was important to avoid too many pathological investigations. Alcoholism, the morphine habit, pregnancy, and a continued state of fever were all also causes of instability of the heat-regulating mechanism: a sort of pyrexial habit seemed to remain in certain cases after actual infection had passed off. The prevalence of an epidemic provided diagnostic indications sometimes, but sporadic cases of all infections were apt to be difficult, and the possibility of "imported" cases often rendered valueless a negative conclusion as regards an epidemic etiology. Certain chronic diseases in the patient were important: chronic nephritis, for example, seemed to render patients more likely to run a temperature for trivial causes. After surgical procedures in septic conditions—for example, a gangrenous appendix—pyrexia often presented a difficult problem, and the conditions to be considered were septicaemia, subphrenic abscess, empyema, or septic pyelophlebitis. A second consideration was whether the infection was exogenous or endogenous. In most acute pyrexial conditions exogenous infection was the cause, the majority of subacute infections being endogenous in origin, but acute endogenous pyrexia did occur—as, for example, in coliform infection of the urinary tract. Where the infection appeared to be exogenous the next consideration should be with regard to the portal of entry, but since there was often nothing left to incriminate the mouth and throat, for example, the next consideration became important—namely, the avenue of spread. The physician should pass under review the various paths by which infection might have spread and each system should receive attention. Despite many negative findings in certain regions, a positive fact often emerged strikingly from a methodical and complete examination. The next consideration concerned the organs particularly affected. The infection was by now embedded and often "cryptic"; certain deep-seated tissues should always be carefully considered in these "cryptic" cases. Bone, for example, was notoriously "silent," while the liver, perinephric and subphrenic regions should also receive careful attention. Sir Thomas Horder had been impressed with the importance of the pleura in certain cases of obscure pyrexia, and pointed out that pleurisy over an aneurysm might cause a very puzzling pyrexia. Certain other considerations were important; for example, the nature of the organism and the type of pyrexia produced should be carefully considered. In this connexion a study of the temperature chart often gave assistance. Lastly, Sir Thomas Horder dealt with certain clinico-pathological features in diagnosis. He pleaded for a thorough clinical examination before pathological investigations were undertaken, and insisted that pathological findings should be carefully interpreted in the light of clinical facts, quoting in this respect the unfortunate result of a laboratory diagnosis of acute lymphatic leukaemia in a case of infective mononucleosis.

Dr. C. E. LAKIN dealt first of all with certain instances of common diseases in an unfamiliar form, and described a case of tuberculous caries of the spine secondarily infected with streptococci and *B. coli*, which ran a curious pyrexia for many months. Another case was that of a middle-aged man with symptoms very like those of typhoid fever, but with persistently negative Widal reactions after several weeks. *Post mortem* it was found to have been a typical case of typhoid, the organism being recovered. Dr. Lakin stated that he had had several cases of typhoid fever recently under his care with negative agglutination reactions. Another common disease sometimes found in an unfamiliar form was pyelitis, and Dr. Lakin described a case of this in which pyrexia was present over a long period, due to a small amount of pus in the pelvis of one kidney. Another group of cases were those in which one condition was superimposed on another. An abscess in connexion with malignant disease of the colon was one such case, and in another malignant disease of the lung with secondary sepsis caused a curious pyrexia. In conclusion, Dr. Lakin quoted two rare cases—one of multiple abscesses in the spleen, and the other an abscess in the psoas muscle caused by *B. pyocyaneus*.

Mr. ZACHARY COPE, speaking from the surgical aspect, stressed the importance of a central pulmonary embolism as a cause of pyrexia in some cases, and also pointed out that malignant disease, especially sarcoma, frequently gave rise to pyrexia.

Dr. DES VOEUX described a case of obscure pyrexia in a woman due to a tapeworm, and pointed out that syphilis was not an uncommon cause of fever of unknown origin. A curious case he had watched for some years consisted of pyrexia in an old woman due to a tuberculous abscess just behind her manubrium sterni.

Dr. HERBERT FRENCH asked for information as to the value of agglutinating reactions in determining which of several isolated organisms was the cause of the patient's disease; secondly, as to whether modern methods of blood culture showed any improvement in recent years; and thirdly, whether any value could be attached to the finding of organisms in the urine of patients, since in any disease the kidney was supposed to try to get rid of the offending organism via the urine.

Dr. F. PARKES WEBER emphasized that tertiary syphilis, especially when affecting the liver, was a frequent cause of pyrexia. Dr. F. G. CHANDLER dealt with the value of a leucocyte count, which enabled a diagnosis between a subphrenic or perinephric abscess on the one hand and typhoid fever and tuberculosis on the other to be made with some certainty. He described one difficult case, and asked for suggestions as to diagnosis. Dr. G. W. GOONHART agreed with Sir Thomas Horder as to the modern regrettable tendency to rush at pathological investigations in these cases. He uttered a word of warning about leucocyte counts, describing a case of paratyphoid infection with a polynuclear leucocytosis. Dr. W. J. ADIE mentioned encephalitis lethargica as a cause of pyrexia in certain cases. Mr. J. E. H. ROBERTS described a case of typhoid fever with considerable leucocytosis which had caused difficulty in diagnosis, and mentioned an abscess in the anterior mediastinum as a curious cause of pyrexia after a mastoid operation. The PRESIDENT mentioned the middle-aged patient with a chronic gall-bladder infection as a type which sometimes presented a curious pyrexia.

Sir THOMAS HORDER, in reply, dealt with various points which had been raised, and, in particular, answered Dr. French's questions. He thought that blood culture methods had not improved in the last ten years; that urine cultures from catheter specimens were of much positive value in obscure pyrexia; and with regard to the agglutination reactions he pointed out that all pathological results were either absolute or relative. Agglutination tests supplied relative data to which undue weight should not be attached.

EXCRETION OF ALCOHOL BY THE URINE IN DRUNKENNESS.

At a meeting of the Medico-Legal Society held in London on January 10th, with Sir WILLIAM WILLCOX in the chair, Dr. GODFREY CARTER and Dr. HERBERT W. SOUTHGATE made a communication, illustrated by lantern slides, on the excretion of alcohol in urine as a guide to alcoholic intoxication. A joint paper by Drs. Carter and Southgate on this subject is printed in the present issue of the JOURNAL at page 463.

The CHAIRMAN, opening the discussion, said that the tests for drunkenness used in this country at the present day were most unsatisfactory, and any scientific method by which an estimate might be made of a man's sobriety would be of the utmost value. The evidence which was produced as regards the quantity of alcohol taken was most fallacious as a rule, and one really could hardly believe a word the accused person said in many cases of drunkenness. The proposed tests of blood and urine were, so to speak, in their infancy, and it would require a large number of observations before absolutely reliable rules could be laid down.

Dr. MACKENZIE WALLIS confirmed as the result of his own investigations the figures given by Dr. Southgate, using the same methods. He had himself found a considerable quantity of alcohol in the urine in tests he had made. But

there was an enormous amount of work to be done before they could generalize, because every case differed as regards tolerance to alcohol. He considered, however, that a case had been made out as to the relation of concentration of alcohol in the blood and urine. Then there was the question of the time of day at which the investigation was made, and the question of the subject's fatigue. There was, he thought, much less tolerance for alcohol in the morning than in the night. There was, further, the question of food. One ought to investigate the effect of the same dose of alcohol on different foods. Dr. Southgate had confined his attentions to bread-and-milk dietaries, and so he suggested that the subject should be given a heavy meal, and then see what concentration there was of alcohol in the blood and in the urine.

Dr. ROCHE LYNCH asked whether any tests of blood and urine had been made in cases of diseases like nephritis. Further, he would like to know whether, if an analysis of the urine or the blood was made four hours after the original dose was taken, and when the graph curve was on the down grade, how far that curve could be made use of to predict the amount of alcohol in the urine or the blood at one hour after the dose was taken when the graph was on the upward grade. Then Dr. Southgate had shown that a lower concentration of alcohol was found in the blood and urine of a heavy drinker than in an abstemious person, and he would like to know how the maximum heights, as shown by graph curves, compared in these cases.

Dr. MORGAN FINUCANE said, as a divisional police surgeon in the metropolis, he was anxious to know how far the tests described could be applied to his own work. He drew attention to the book issued by the Board of Control during the war entitled *Alcohol: its Action on the Human Organism*. It was a scientific investigation of all known tests of the effects of alcohol, and its conclusion was that little or no alcohol was excreted in the urine. He did not see how a standard could be fixed. What they had just heard was an absolute contradiction of all contained in that book, issued by a committee composed of distinguished men like Sir George Newman and others. He could not imagine any police station in London setting up convenient urinals for the purpose of getting specimens of urine—nor could he imagine the Treasury providing the money. They must be practical people. It seemed to him that this was as far-fetched a theory as the examination of the spinal fluid suggested by a distinguished physician a few months ago on the subject of drunkenness. He thought they must rely upon experience and common sense and upon the evidence, which in most cases was trustworthy. He did not believe that there was a public demand at all for the boiling down of drunkenness to scientific tests or to one or two symptoms. It could not be done. It was not what the public wanted or what courts of law would allow. The test of drunkenness was really the conduct and the behaviour of the individual when the accused had passed through the whole gamut of arrest and observation by the police. In his experience the police were absolutely fair and just and humane men engaged in eliciting the truth. He was not a partisan of the police. Very often he had stood between the prisoner and the police. Dr. Finucane referred to the symptoms of flushed face, dilated pupils, congested eyes, rapid pulse, which, he said, were in themselves trivial. It was above everything the conduct, the loss of control, the self-criticism of the individual, the application of common sense, and the effect on the nervous and muscular systems of the prisoner—these gave a picture of which they could seldom be mistaken if experienced in these matters, and bearing in mind the whole history of the case. The lecturer had said that in cases of chronic alcoholics there was little or no concentration of alcohol in the urine. Motorists were usually people constantly drinking, and therefore he suggested that the concentration of alcohol in such cases would not exist in the same way as it would in the urine of abstainers. As a police surgeon engaged in this sort of work, he maintained that nothing would come of this private inquiry. Every case ought to be decided on its merits, and they could with confidence leave the decision to magistrates possessing wisdom and experience,

who always gave the accused the benefit of any reasonable doubt.

Dr. A. S. WOODWARD said he would like to know the result of scientific investigation into the question of how far food neutralized high concentrations of alcohol in the blood and in the urine.

Sir BERNARD SPILSBURY suggested that the concentration of alcohol in the urine might vary considerably according to the amount of urine secreted before drink was taken. A man was not at all likely to empty his bladder just a few minutes after his arrest in order that a specimen should be taken of his urine. An enormous amount of work was still to be done before a reliable test could be placed before them.

Dr. B. A. LEVINSON thought a person accused of drunkenness should be given an opportunity of standing the test. Magistrates must long for some standard whereby the police evidence could be tested.

Dr. CORBETT said it was pathetic to see two doctors ranged against each other on a question of drunkenness. If, in cases where patients entered hospitals, records were kept of urinary and blood tests, such records would be invaluable for use in High Court actions.

Sir WILLIAM WILLCOX reminded the audience that it was as a result of a test of a specimen of urine sent to the Home Office in the Armstrong murder case that he was able to say that a fatal dose was given three days before. That showed what could be done in cases of arsenic in the urine.

SOLID TUMOURS OF THE VULVA.

At a clinical meeting of the North of England Obstetrical and Gynaecological Society at Sheffield on February 19th, the President, Mr. W. GOUGH (Leeds), in the chair, Mr. A. LEYLAND ROBINSON (Liverpool) showed two solid tumours of the vulva.

Mr. Leyland Robinson said that the two patients with tumours of the vulva were operated upon within a short time of each other, and both were sent to the hospital with a diagnosis of Bartholin's cyst, but proved to be solid tumours of an uncommon type. A fibromyoma of the vulva was removed from a multipara aged 33, who complained of a lump which had been present for five or six years. On examination a hard, smooth, discrete, and freely mobile tumour was found beneath the skin of the right labium majus with the labium minus stretched over its median surface. The position of the lump closely resembled that of a Bartholin's gland. There was nothing pertinent in the past history and, in particular, no evidence of gonorrhoeal infection. The lump was excised without difficulty, and as its chief point of attachment was at the upper or inguinal pole it was probable that the tumour arose from the terminal vulval fibres of the round ligament. Microscopically it was clearly a fibromyoma, and would be called a dermoid by some pathologists. Dermoids were described as connective tissue tumours of the female abdominal wall, which displayed active growth during pregnancy, and were related pathologically to the fibrosarcomata. The probability was that dermoids were merely fibromyomata, arising in the round ligaments, or some outlying or displaced rest of myometrial tissue, which grew in unison with the uterine muscle during pregnancy, and that the cellular appearance produced by this decidua or pregnancy reaction had been mistaken for malignancy, and led to the incorrect inclusion of these tumours among the sarcomata. The second case was one of carcinoma of Bartholin's gland removed from a widow aged 55, seventeen years past the menopause. There was no history of gonorrhoea or any serious illness. There had been four abortions, the last one twenty years ago, and no full-term labours. The patient complained of some dragging pain in the vagina, and of a lump in the vulva which was first noticed four months before she had sought advice; it had been getting bigger lately. A swelling the size of a hazel nut was found in the right labium majus, in the anatomical position of Bartholin's gland. It was slightly tender and solid in consistency. The overlying skin was perfectly normal in appearance and mobility. No glands could be felt in either groin. Local excision only was performed—

partly because the patient's general condition was very poor, and partly because the diagnosis of malignancy rested on suspicion alone. There were no enlarged glands, and it was thought that, this type of malignant disease being very rare, the lump might turn out to be a simple adenoma. A small secondary haemorrhage occurred on the ninth day of convalescence, but otherwise the patient made a smooth recovery, and remained well at the present time, seven months later, during which period she had been under treatment by x-ray therapy. Herbert Spencer in 1913 had published a similar case, and included in his paper thirteen collected from the literature, of which only one had been published in English periodicals. The published records of this condition were, therefore, extremely rare, and Mr. Leyland Robinson believed that his case was the first reported to the society. Spencer had stated that these tumours were harder than an inflamed gland, nodular on the surface, and associated with bluish discoloration of the skin and oedema of the hymen, but fourteen cases were too few for dogmatism, and practically none of these points were seen in the case now reported. Of the fourteen examples collected by Spencer, in only one was there any positive history of gonorrhoea, and in only three was leucorrhoeal discharge a feature, so that previous infection had little, if any, etiological significance. Congenital abnormality was noticed in two cases, Bartholin's gland being apparently absent on the opposite side of the tumour. The pathological appearances varied greatly, and little agreement existed among the fourteen authors. In three cases the growth was described as "carcinoma" only; in two as "cylindrical carcinoma," and the remainder as follows: "melano-carcinoma," "tubular carcinoma, partly scirrhus," "carcinoma parvi cellulare," "canerose carcinoma," "adenocarcinoma," "villous carcinoma," "squamous-celled carcinoma," and "adenocarcinoma, resembling squamous." Spencer had pointed out that these pathological differences were associated with the fact that the epithelium lying around the acini and ducts varied considerably in shape and arrangement, and hence the gland might well give rise to tumours of diverse appearances. He quoted Jambon and Chaboux, who examined the glands of several young adults after death. They stated:

"The excretory ducts appear in the middle of the gland in the form of irregular cavities, reaching even to the middle of the acini. They present an epithelium either of one or several layers of cubical cells. Generally as the duct increases in calibre and importance its epithelial lining becomes thicker. The cells are only half the size of the secretory cells of the acini, and consist of a large nucleus surrounded by a thin layer of granular protoplasm; near the termination of the common duct the superficial layers of the lining epithelium tend to become squamous."

These authors said nothing about distinctly cylindrical epithelium in the duct, though this was mentioned by de Sinety, Klein, and Langerhans.

In the present case there could be no doubt that the tumour was an adenocarcinoma. These growths were said to be of great malignancy, and of the fourteen patients mentioned by Spencer, only one, Trotta's, was alive and well for so long as six years after operation. It was interesting to note that no glands were removed in this case, as in Mr. Robinson's, whose progress he hoped to report to the society at some later date.

Ovarian Cyst in a Girl of Eleven.

Mr. Leyland Robinson also showed a specimen removed from a healthy, well developed girl, 11 years of age, who had complained of abdominal discomfort for one week. A tumour formed a marked prominence in the lower abdomen, extending up to the umbilicus. It had all the physical signs of a simple serous cyst, and the diagnosis presented no difficulty. A vaginal examination, which was made under anaesthesia immediately before operation, disclosed a typical dermoid consistency of the lower pole of the swelling, and suggested the dual pathological nature of the tumour. Removal was easy, and convalescence uneventful. It was noticed at the operation that while the conformation of the external genitalia was normal, the uterus was noticeably narrow and elongated, the probable result of pressure from the tumour, and perhaps of hypofunction of the ovary. The specimen proved to be a bilocular cyst, the lower loculus showing the usual

characters of a dermoid, and the upper one those of a serous cystadenoma. The cases were not very uncommon in children under 10 years of age, for Bland-Sutton had collected 100 cases, and Howard Kelly published 126 cases in 1901, of which 55 were unilocular or multilocular cystadenomata; 47 were dermoids and 24 solid tumours of the ovary. Many tumours had been successfully removed from quite young infants. D'Arcy Power operated on a child of 4 months, and MacGillivray in 1908 described a very interesting operation at which he had successfully removed a cyst completely filling the abdomen of an infant of 11 months.

So far as Mr. Robinson was aware, the last time the subject was discussed in the society was in 1910, when Mr. Cuff showed a dermoid removed from a child of 9 years. During the discussion Mr. Lloyd Roberts had related three cases, all dermoids, Dr. Rabagliati two, also dermoids, and Professor Donald one case of a solid tumour, said to be a sarcoma, although the patient was free from recurrence for three or four years after operation. The chief points of interest in the present case were that although the tumour was of a fair size there was an almost complete absence of symptoms which were generally those of an acute abdomen, and due to torsion; there was also the association of a dermoid cyst with a serous adenoma, and the attenuated appearance of the uterus, with the possibility of persistent infantilism as a result of the loss of the left ovary. Such a condition would appear to offer an excellent opportunity for the use of glandular extracts during pubescence. Mr. Robinson thought it would be interesting to know how many cases of this type the fellows and members of the society had seen during this interval of sixteen years.

Double Placenta with Placenta Praevia.

Dr. D. DOUGAL (Manchester) showed a specimen of double placenta from a case of placenta praevia.

The patient, a primipara, 30 years of age, had a severe attack of ante-partum haemorrhage at the thirty-fourth week, and was admitted to hospital. On admission the haemorrhage had ceased, and there was no dilatation. The foetal heart sounds could be heard well; the head was presenting, but high up, and there was a distinct resistance felt in the lower uterine segment, which was thought at the time to be due to a placenta praevia, or possibly to concealed haemorrhage. There was no further bleeding, and the patient was kept at rest for three weeks. At the end of that time she had slight pains, and the membranes ruptured. Vaginal examination showed the cervix to be very little dilated. A few hours later the cord prolapsed; an anaesthetic was given, and attempts made to replace it. During these attempts, which proved unsuccessful, there was profuse haemorrhage, and the pulsations in the cord ceased. The child being dead, and no further bleeding taking place, the patient was allowed to deliver herself, and this she did about ten hours later.

The specimens shown were the placenta, membranes, and cord. The placenta was double, but the two halves approximated each other at their distal extremities, and both lobes reached the edge of the opening in the membranes. The insertion of the cord was at the inferior margin of one lobe, the vessels to the other lobe covering an intervening area of membrane. One lobe was supplied by the main trunks of the umbilical arteries and vein, but the other lobe obtained its supply from a subsidiary branch of one artery and vein. The vein to this lobe ran along the edge of the opening in the membranes, and would be very liable to pressure or actual injury during delivery or intra-uterine manipulations. Dr. Dougal thought it very possible that something of this sort happened during attempts to replace the cord. With the number of anatomical abnormalities present in this case—namely, placenta praevia, marginal and velamentous insertion of cord, and an exposed vein on the edge of the opening in the membranes—the chances for the child were evidently very poor indeed. The combination of placenta praevia and low insertion of the cord not only favoured prolapse of that structure, but also made replacement difficult, if not impossible.

Chronic Inversion of the Uterus.

Dr. DOUGAL also reported a case of chronic inversion of the uterus. A married woman, aged 24, consulted him in October, 1925. She complained of constant bleeding, which commenced six weeks after her confinement, fourteen

months previously. At the confinement the child was born without intervention, but the placenta was retained, and had to be removed manually. She stated that she was in a condition of shock at the end of the labour, and that her convalescence was slow. The patient was extremely anaemic. On vaginal examination a soft swelling was felt protruding through the cervix, and there was a fair amount of bleeding on handling this tumour. The fundus of the uterus could not be felt in its normal position, so a diagnosis was made of chronic inversion, and the patient admitted to hospital for treatment. Dr. Dougal tried to reduce the displacement with a repositor, but was unsuccessful, and therefore decided to perform Spinelli's operation, which was really an extensive anterior hysterotomy, but he found it somewhat awkward to carry out, owing to the inverted structures. He had to incise the anterior wall of the uterus as high as the fundus before it was possible to reduce the displacement. There were no adhesions present at the neck of the sac, but the peritoneal surfaces about the fundus were adherent to one another, and on separating these he found the remains of a partially atrophied fibroid, about the size of a bean. He excised this tumour, and then stitched up the uterus. There was a good deal of oozing, which he was unable to control completely, so he was compelled to leave a narrow gauze drain in contact with the anterior uterine wall. The vaginal wall was then sutured in the usual way, a small part being left open for the gauze to pass through. The patient made an uneventful recovery, and was now, three months later, menstruating regularly and losing a normal amount of blood at these times. There were one or two interesting points about the case. The inversion might have been caused by extracting a partially separated placenta, but on the other hand it might have been spontaneous, the fibroid tumour at the fundus of the uterus playing some part in the process. The failure to replace the uterus with the repositor was no doubt partly due to the fact that the anterior and posterior surfaces of the uterus were adherent in the neighbourhood of the fundus.

Ruptured Uterus.

Dr. C. P. BRENTNALL (Manchester) reported a case of ruptured uterus in a woman, aged 38, in her sixth pregnancy.

The first four labours were normal and at full term, the fifth was premature, and the child was stillborn. There was a minor degree of pelvic contraction, the transverse measurements being normal, and the conjugate slightly reduced; the external conjugate measured less than seven inches. There were no abnormalities during pregnancy, and labour began about the estimated date. Pains started at 8 a.m., and continued all day until about 5.30 p.m. They were probably not severe, as the woman did not summon the midwife until the afternoon. There was a prolonged interval between the pains at this time, and the woman was still going about the house when her husband returned from work at 5.30. The membranes ruptured shortly after this, the uterine contractions recommenced, and she went to bed. She stated that she bled a good deal during the evening, but this was doubtful, as the midwife did not send for a doctor until about midnight. The pains continued without intermission until 2.30 in the morning. She was seen by two doctors about midnight, and was immediately sent off to hospital with the diagnosis of impacted breech; there appears to have been no attempt at any operation. She arrived at hospital at 2.30 in the morning. Labour had then lasted eighteen and a half hours, and the membranes had been ruptured nine hours; she was very pale, and in a state of shock. Abdominal examination revealed the obvious fact that the uterus was ruptured. The body of the foetus could be felt to one side, and the contracted uterus to the other. The lower abdomen was very tender, and she complained of pain in the left shoulder. The foetal head was quite low down in the pelvis, lying in the transverse diameter, and there was a depressed fracture of the posterior parietal bone; the foetus was delivered by craniotomy and the placenta removed manually. Dr. Dougal had considerable doubt whether the woman would stand an abdominal section, but it appeared her only chance. On opening the abdomen he found a longitudinal tear of the uterus, extending from about the attachment of the round ligament, and involving also the upper part of the vagina. Both layers of the broad ligament were torn across, but the Fallopian tube and infundibulo-pelvic ligament were intact. The uterus was removed as rapidly as possible by panhysterectomy, and the vaginal wound closed. The pelvis was drained by a rubber tube in the lower angle of the incision.

There were one or two unusual features about the case. Ruptures of the uterus were of more frequent occurrence in the minor than in the major degrees of contracted pelvis,

and they were commoner in multiparae than in primigravidae. But in such cases there was generally a history of dystocia, and the supposition was that some undetected injury to the soft parts gives way at the subsequent labour. In this case the pelvic contraction was of a very minor degree, the pelvis being of the simple flat variety, and all the previous confinements had been completed without difficulty or undue delay. There was no early rupture of the membranes, and if it was assumed that the second stage of labour began when the waters broke its total duration was not more than nine hours. The most unusual feature of the case appeared to be that the head had passed the brim, and was well down in the pelvis.

Professor W. FLETCHER SHAW (Manchester) read a note on two cases of Wertheim's hysterectomy complicated by double ureter. The PRESIDENT showed a specimen of carcinoma of the cervix in a woman, aged 29, and described a case of adenomyoma of the uterus. Professor J. S. C. DOUGLAS and Mr. W. W. KING (Sheffield) jointly demonstrated a specimen of mucocele of the appendix.

ERRATUM.

In the report of the meeting of the North of England Obstetrical and Gynaecological Society on February 6th (p. 243) the name "Miss Brookfield" should have been "Mr. R. W. Brookfield."

UTERINE IMPLANTATION OF THE HUMAN OVUM.

At a meeting of the Edinburgh Obstetrical Society held on February 10th, with the President, Dr. R. W. JOHNSTONE, in the chair, Dr. JAMES YOUNG read a paper on the embedding changes in the uterine mucosa as studied in an early human ovum.

Dr. Young said that the ovum was situated in a completely closed implantation chamber, but extending from its outer surface through the entire thickness of the mucous membrane there was a narrow stalk of trophoblast which indicated the track of entrance. Externally it measured 1.5 by 0.77 by 0.6 mm., and the trophoblast consisted of the usual dual cellular elements. There was no evidence of the vacuolation of the syncytium present in the Bryce-Teacher ovum, which Dr. Young believed to be probably abnormal. The blastocyst measured 0.44 by 0.3 mm.; it was filled by mesoblast and there were no villi. The embryonic area was too badly damaged to allow of a satisfactory study. The ovum in its general features resembled the two earliest ova so far described—namely, those of Miller and Kleinhans. The maternal changes were similar to those which Dr. Young had described in 1910. To understand these changes it was necessary to remember that the uterine mucous membrane was unique among the tissues of the human organism in so far as its function, both during the menstrual cycle and during pregnancy, was fulfilled by a discharge of blood from its vessels. The mucosa thus bled in anticipation and it bled again with realization. Despite the unique character of this phenomenon it had often been believed that the menstrual bleeding and the bleeding of pregnancy were necessarily two different processes. In one case it was due to the ovarian "hormone," whilst in the other it was thought to be due to the active destruction of the vessel walls and the mechanical liberation of the blood. But if the bleeding that was essential to placentation could be accomplished in this mechanical way, why, it was asked, had there been built up all the physiological and structural complex, the obvious function of which was an immediate opening up of the vessels and a discharge of the blood at the very regions where the ovum could be expected to appear? In his previous work Dr. Young professed to have solved this obvious dilemma by showing that the bleeding of the menstrual cycle and the bleeding round the engrafted ovum were essentially similar and were due, in each case, to the response of a specially constructed and specially sensitized tissue to a biochemical material. He had shown that during pregnancy the vessels opened up in a way which was exactly similar to that operating in the premenstrual phase. His views published sixteen years ago regarding the essential similarity of the menstrual and placental "hormones" in so far as the uterine changes were concerned

had been supported by the recent work of Allen and Doisy and others, who had shown that pro-oestral changes in ovariectomized animals could be induced by both ovarian and placental extracts. Dr. Young had previously shown that the ease with which this "bleeding" response occurred was due to the fact that the stroma of the mucosa consisted of a soft undifferentiated tissue, in which the vessels were devoid of any supporting elements—muscle or fibrous or elastic tissue. The nature of the maternal reaction in his present very early ovum confirmed Dr. Young's previous results. In a wide zone round the implantation chamber the vessels were expanded in a sinus-like manner, and in areas distant from the trophoblast their contents were being poured freely into the stroma. The result of this bleeding response to the chorionic secretion was a virtual advance of the nourishing blood fluids towards the ovum, and, in the immediate vicinity of this, a pouring of the blood into the implantation chamber from vessels, which were thus like rivers that had overflowed their banks. Only by an understanding of these phenomena could the function of the decidua be appreciated. It was obvious that these maternal changes were temporary and had as their sole purpose the meeting of the needs incidental to embedding. After this had been accomplished and a sufficient blood supply was provided it was clear that the active displacement of tissue which they implied had to be arrested. This later and entirely different phase in placentalation could only be possible in one or other or both of two ways—by a suspension of the chorionic secretion or by a protective mechanism on the part of the maternal tissues. Dr. Young in this connexion showed sections of pregnant tubes in which the only regions where the tissues were protected against a tearing up by the oedematous and haemorrhagic escape provoked by the chorionic secretion were the regions, in the mucous membrane, where a decidual reaction had occurred. He believed that in the uterus in normal pregnancy the decidua acted in a similar way. A recognition of these facts could alone explain why the whole mucosa—the whole of the sensitive tissue—must necessarily undergo a decidual change.

SANOCRY SIN IN TUBERCULOSIS.

At a meeting of the Leeds and West Riding Medico-Chirurgical Society on February 26th, Mr. A. L. WHITEHEAD, the President, in the chair, a paper was read by Professor T. R. ELLIOTT of University College Hospital, entitled "Sanocrysin in tuberculous infections."

Professor Elliott described briefly the pioneer work by Professor Moellgaard and Dr. Secher, and narrated the progress of clinical observations with sanocrysin in Great Britain during the past fifteen months. The earlier observations had emphasized the serious dangers that might arise if a case of heavy infection were treated, or if the drug were pushed repeatedly at too close intervals, such as in 1-gram doses every three or four days. Later experience, both in Denmark and in England, had shown that the dangers could be lessened by milder treatment with 1/2 or 1 gram doses at intervals of from one to two weeks. By this method dangerous conditions of tuberculous intoxication were lessened and there was rarely need to use the special serum; there was also less probability of metallic poisoning of the kidneys, liver, or skin. Fournier and Mollaret in Paris, using a similar gold salt, on Levaditi's suggestion, in human syphilis, found that intensive dosage arrested the syphilitic infection and reversed the Wassermann reaction, but milder treatment failed to abort the lesions or to affect the Wassermann reaction; it was therefore probable that the milder method in tuberculous infections might be similarly much less effective. Professor Elliott described four consecutive cases in which great improvement followed the use of sanocrysin; the best results were seen in patients with recent and active tuberculous inflammations. It was absolutely necessary that the patient should be in bed under constant medical supervision so that any untoward development could be observed at once and the treatment modified.

Dr. DE CARLE WOODCOCK (Leeds) thought that the time was ripe for the introduction of some drug in the treatment of tuberculosis. He himself had hoped that manganese

would prove useful, and although the results were disappointing, yet he thought that one of the heavy metals might be found as effective as arsenic had been in syphilis.

Dr. RAWDON VEALE asked for information as to the value of the drug in the treatment of lupus. Dr. E. SMITH (Harrogate) inquired whether it had been tried in cases of renal and bladder tuberculosis.

Professor ELLIOTT thought it unlikely that sanocrysin would prove useful in lupus and in renal tuberculosis.

Mr. H. B. SCARCELL (Leeds) demonstrated a series of radiographs by means of lantern slides, and Dr. T. WARDNOR GRIFFITH (Leeds) gave a lantern demonstration on the action of quinidine sulphate in auricular fibrillation.

ENDOCRINOLOGY AND OLD AGE.

A MEETING of the Nottingham Medico-Chirurgical Society was held on February 18th, the President, Mr. H. BELL TAWSE, in the chair, when Dr. LEONARD WILLIAMS gave an address on endocrinology and old age.

Dr. Leonard Williams stated that the diseases and disorders of old age might be reduced to a common denominator in the word "circulatory." The circulation was complete and fully equipped at birth; it underwent no evolution and knew no respite. It was the commissariat of the bodily economy. Its only vice was its capriciousness; in one case it might give a vigorous digestion and a sluggish brain, in another a brilliant mind and chronic dyspepsia. It determined growth and muscular development, and it was by its default that man, having waxed, began prematurely to wane. The delicate highly organized structures were the last to be developed and were often the first to fail. Man grew old "in bits," and the portions of him which lasted longest were those which were most fully employed. A man's brain might thus continue active at the expense, as it were, of his muscles, joints, and other tissues. So far as existence was concerned the stomach was a key industry, which the higher centres were not. The only key industry in the brain was the medulla. When the stomach required more blood the higher centres resigned their rights. The circulatory system was in a large measure subservient to other systems, especially to the endocrine system, the oldest in the evolutionary series being the suprarenal, which presided over the circulation, muscular activity, assimilation, excretion, and reproduction. Alone among the endocrine organs, it hypertrophied with advancing years; the others atrophied. In the first half of the second month of intrauterine life the suprarenals were twice as large as the kidneys, and the disproportion in size was due entirely to an excess of cortex over medulla. The adrenal had been called the gland of fight and flight; a large cortex implied a combative disposition, a thin cortex a submissive nature. Dr. Leonard Williams instanced constipation as one of the minor penalties of advancing years, and one which occasionally so upset the patient's nerves as to send him definitely off the rails, and recalled the advice of Sir George Macleod, who used to say to his students, "Beware of the man who carries his head in his rectum, for one day he will commit suicide." He suggested three remedies, all sedatives, which were usually efficacious—petroleum and agar-agar, taxol, and belladonna. Although a convinced disciple of Arbuthnot Lane, he had not infrequently thought that Nature conferred a measure of constipation on old people for a very beneficial purpose. A man dug his grave with his teeth, and overeating hastened old age. In most mental hospitals overfeeding was rampant. Referring to the modern methods of rejuvenation, he remarked that it was extraordinary that physiologists had not been able to decide whether the testicular hormone was secreted by the interstitial glands or in the tubuli seminiferi. At the moment opinion seemed to be in favour of the tubules, and if this were correct Steinach's operation would be deprived of all physiological support. Whether the results of this operation were good or bad, there was this to be urged against it, that it was a mutilating operation. With Voronoff's grafting operation it was far otherwise. It could be repeated half a dozen times on the same patient, and often led to an increase in

strength and a prolongation of life; he had not yet come across one case which had been a failure, though he had heard of such. Some patients were more benefited than others, and some took longer than others to experience the benefit. The operation was designed to conserve mental and muscular vigour in the declining years; it was not designed to restore copulative capacity to senile impotence, and it never did so.

At a meeting of the Liverpool Medical Institution on February 18th Dr. FRANK H. BARENDT read a short paper on prurigo, and showed a male patient, aged 13, suffering from prurigo ferox s. agria. He gave a brief history of the term, first used by Hebra to describe this inveterate skin disease, frequently called Hebra's prurigo. Dr. Barendt drew attention to, and afterwards demonstrated on the patient, the salient features: the thickened skin of the shins; the scattered scratched papules, and the presence of the so-called "prurigo buboes." The differential diagnosis between urticaria, eczema, and especially scabies, was set forth, for these sufferers were frequently treated for these diseases, especially scabies. There were remissions at times, but cure *in sensu stricto* could not be effected. Dr. Barendt considered that the clothing next to the skin should be cotton or linen, not wool, bathing should be used sparingly, and the integument should be kept emollient continuously. It was his experience that such measures alleviated the intolerable itching. Internal treatment was of no avail, although bromides were sometimes useful in allaying the restlessness at night, when this condition was superadded to the pruritus.

Reviews.

THE COCAINE HABIT.

PROFESSOR HANS W. MAIER of the Psychiatric Clinic, Zürich, in his book *Der Kokainismus*, deals exhaustively with all aspects of the cocaine habit. The first chapter contains a description of the use of coca leaves by the natives of South America, and the next two give a short account of the chemistry and pharmacology of cocaine.

The main portion of the book is devoted to a detailed description of the cocaine habit. Its establishment among white races is an interesting but very sad chapter in medical history. Tschudi first brought coca leaves to the notice of European science, and their action in stimulating the central nervous system was at once recognized, and Samuel Percy observed the local anaesthetic action of the leaves on the tongue as early as 1856. In 1860 Niemann isolated the alkaloid cocaine, and also noted its local anaesthetic action, but it is a remarkable fact that no general use was made of cocaine as a local anaesthetic until 1884. Meanwhile, however, the drug had attained notoriety because, in 1878, certain doctors in the United States tried it as a cure for the morphine habit, and found that it had a marked action in relieving the desire for morphine in habitués. This discovery attracted very general attention, and the new cure for morphinism was taken up with enthusiasm in Italy and in Germany. It was not long before it became manifest that the cure was worse than the disease, because the cocaine habit was even more destructive than the morphine habit. In 1885 Erlenmeyer drew attention to these dangers, and pointed out that the spirits brought in to help were really destroying fiends. In this manner, however, the cocaine habit first became established on the Continent and in the United States. Apparently the habit died out again in Germany, for in 1899 Leudesdorf suggested the use of infusion of coca leaves as a cure for alcoholism. This is an interesting example of the shortness of the memories of medical men, because only fourteen years before the whole medical press of Germany had been filled with warnings against the use of cocaine in the treatment of drug addiction.

The cocaine habit spread steadily but slowly in the first decade of this century, and by 1914 its use was very common among the prostitutes in the large towns of Europe. The war led to a rapid spread of the habit, and after the war it extended with most alarming rapidity. In the United States official figures show that the use of cocaine is diminishing, and in England it does not appear to be increasing, but in Germany and Switzerland the habit appears to be spreading very fast.

The author describes the psychological effects produced by cocaine in considerable detail, and his general descriptions are supplemented by accounts of experiments carried out by himself on cocaine addicts and others. Cocainism is essentially a sociable vice, for the cocaineists usually form clubs and take the drug in company. In this respect cocaine resembles alcohol and differs from morphine. The general effects of cocaine administration are a feeling of euphoria and a subjective sense of activity and excitement. Psychological tests on cocaineists show that the administration of cocaine actually produces a true stimulation of the higher centres of the brain, and increases the speed with which numerous tests can be performed.

One special action for which the drug is much used by cocaineists is, however, its effect in producing sexual excitement. This action is most marked in women; in them cocaine produces an increase of sexual desire and also an increase of sexual powers; indeed, often it produces a condition resembling nymphomania. In men sexual desire also is increased, but usually the sexual powers are reduced. The author gives extensive reports of cases which illustrate the habits and morals of cocaineists. The general picture is one worthy of the pen of Swift, and, indeed, reminds us of his Yahoos. The old statement that cocaine produces more rapid moral, mental, and physical degeneration than any other habit-forming drug appears to be, if anything, an understatement. Nevertheless, the author concludes that cocaine is not as powerful a habit-forming drug as morphine, since the removal of the drug from an addict does not produce a violent physical reaction such as occurs if a morphinist is suddenly deprived of his drug. For this reason the author concludes that abrupt withdrawal of cocaine from addicts is practicable, and that no doctor should prescribe cocaine even to the most confirmed addict.

The legal aspect of cocaine addiction is discussed in the last chapters of the book. The terms of the Hague International Convention of 1912 are discussed, and an account is given of the various conferences on dangerous drugs that have been held at Geneva under the auspices of the League of Nations, a subject with which our readers are familiar. The book concludes with the following urgent warning as to the possible dangers of any extension of drug habits: "People talk much of the horrors of gas warfare, but do not realize sufficiently that the threatened spread of the abuse of such violent poisons as cocaine might develop into a much greater danger to the community. To-day it should still be possible to nip this developing pest in the bud. Let us hope that this may happen, and that this description of its origination and nature may soon be of interest only to the historian either of medicine or of the social evils of our epoch."

CHRONIC PANCREATITIS WITH JAUNDICE.

Is a monograph much on the lines of a good inaugural thesis, though it does not appear to be one. Dr. PIERRE MALLET-GUY discusses all the features—etiological, clinical, diagnostic, and surgical, for, as the cure is drainage, he considers it a surgical disease—of chronic pancreatitis accompanied by jaundice, with special reference to the value and the remote effects of the operation of cholecystogastrostomy. This study has entailed much labour, for he accepts, after critical consideration, 106 cases of this syndrome, and gives extensive references, including important English writings, which extend over more than forty pages. In addition, a large number of cases, some of them previously unpublished, are quoted in illustration of his arguments.

² *Pancréatites chroniques avec ictere (causes, diagnostic et traitement): valeur et résultats éloignés de la cholecystogastrostomie.* Par Dr. Pierre Mallet-Guy. Préface de M. le Professeur Bérard. Paris: Masson et Cie. 1925. (Roy. 8vo, pp. 307; 8 plates, 15 figures. 25 fr.)

¹ Dr. Hans W. Maier. *Pathologie, medizinische und behördliche*. Dr. Hans W. Maier. Leipzig: G. Thieme. 1925. 22 figures, 12 plates. Paper cover, R.M. 10; bound, R.M. 17.50.)

The condition may occur at any age between 8 and 74, but the average age is between 40 and 45, and the female sex provides a majority of the victims. The important causes are, in the first place, infection of the biliary tract, a view which is thoroughly accepted, and in the second place syphilis, of which examples are brought forward. This symptom-complex, which most often imitates a calculus in the common bile duct or carcinoma of the head of the pancreas, cannot, Dr. Mallet-Guy insists, be diagnosed on clinical grounds with certainty. The gall bladder may be distended or collapsed, probably corresponding respectively to its being healthy, as was recorded in 70 per cent. of the cases, or small and collapsed. The operative treatment is very exhaustively discussed. Cholecysto-gastrostomy, first systematically employed by Jaboulay, has the advantage first of simplicity, rapidity, and freedom from risk at the surgical operation, and secondly of not interfering with gastric digestion; on the other hand, an ascending infection, usually confined to the cavity of the gall bladder, is common. On the whole the operation of choice is regarded as simple cholecystostomy. The monograph is well illustrated with radiograms, showing especially the appearances in cholecysto-gastrostomy.

OPHTHALMOLOGY.

SWANZ's *Handbook of the Diseases of the Eye*, edited for some years by Mr. LOUIS WERNER, has now reached its thirteenth edition.³ The handbook is too well known and too well appreciated by English-speaking students to require more than a short note. The present edition conforms very closely with its predecessors, only a few minor alterations and additions having been made to bring it up to date since the appearance of the last edition in 1919. These have, however, entailed an increase in bulk of some twenty-five pages, which is unfortunate, perhaps, since for its purpose the book is large enough. The main changes affect the chapter on the diseases of the uveal tract and retina, diseases of the choroid having been transferred *en masse* from the former to the latter. Five new illustrations have been added, and the index has been revised and enlarged; even yet this latter would be greatly improved by further elaboration. The handbook has attracted a very large public in the past, and to-day it is one of the best and most convenient treatises of its kind in the language.

The literature on ophthalmic plastic surgery is extensive, but hitherto it has remained scattered in the periodical journals of various countries, while in the ordinary textbooks on ophthalmology, and even in those confining themselves to the operative aspect of this branch of surgery, sufficient space has not been allotted for the proper exposition of what is admittedly a very specialized and very technical branch of the subject. Dr. SPAETH's book, *Newer Methods of Ophthalmic Plastic Surgery*,⁴ is the first in English literature to gather together and systematize this scattered knowledge; at the same time he adds largely to it from his own intensive and extensive experience, gained largely in the great war, and continued since then in the modified conditions of civilian life. The first part of the book deals with the general methods of plastic surgery of the face, the formation of flaps and grafts of various kinds, the use and choice of prostheses, and the highly specialized technique which experience has shown to be necessary if results of any cosmetic value are to be obtained from these difficult procedures. The second part deals with individual types of deformity and their appropriate treatment, ranging from such small and relatively minor conditions as ectropion and trichiasis to complete restorations and reconstructions of the socket, whether after injury or after the extensive removal of tumours. The well known methods of operative ophthalmic surgery that are connected with pathological changes are not

included as a general rule, inasmuch as their treatment is already established and well understood, but in several cases where methods of grafting are advised, as in symblepharon, or where newer methods have been introduced, as in ptosis, these conditions have also been considered.

The tragedy involved in the deformed face is difficult to realize adequately, and its consequences, both from a psychological and an economical standpoint, are very serious. Moreover, in many cases an eye with all its value is sacrificed, when by bold and imaginative plastic surgery it could be saved. As a general rule the practising ophthalmic surgeon has not the experience of these cases which would enable him to put at the service of his patient all the knowledge to which this specialized department has attained. The book is planned to suit the needs of the general ophthalmologist in his everyday practice, but we think that the author is somewhat optimistic in his contention that the results attained in each case should closely approach 100 per cent. perfection. The building up of a reconstructed face is not a matter that can in any sense be done by rule of thumb; each case must be thought out and treated only after the most careful and individualistic study; to get results at all approaching perfection the operator must combine dexterity in the "carpentry of surgery" with the art of the sculptor and the imagination of the artist, and must be assisted by no small amount of patience and sympathetic co-operation on the part of the patient. As a basis whereon to build up a technique, and as a guide to the most auspicious method to employ, this book should prove valuable; it undoubtedly fills a gap in English ophthalmic literature. It is well written and well printed, profusely illustrated, and by no means its least valuable feature is the excellent bibliography it contains.

HEALTH MANUALS.

The Health of the Workers, by Sir THOMAS OLIVER, is one of the series of Modern Health Books⁵ now being produced under the editorship of Professor D. FRASER HARRIS. The author sets out to meet the growing interest taken by the public in the medical and social problems connected with industrial occupations. The result is an entertaining, if somewhat discursive, little book, wherein the worker may learn much of the diseases and injuries incidental to various occupations: the efforts made by medical inquirers to unravel their cause; and the measures that have been taken during the last hundred years, by the State or in other ways, to remedy the conditions. Sir Thomas Oliver describes what factories are, and what they might be. He tells of the diseases incidental to industry, and of industrial accidents. In the chapter on industrial poisons we have the story of the inquiry by Sir Thomas Oliver and Sir T. E. Thorpe into lead poisoning in the Potteries, and the great reduction in the prevalence of plumbism that followed the adoption of their recommendations. In the chapter on dust there is an interesting discussion of the cause of the high mortality from pulmonary phthisis amongst printers; and in the chapter on miners the public is reminded that coal miners are healthier than average males of the population, though their liability to death by accident is two and a half times greater. As is natural in the medical expert of the Home Office Special Committee on Dangerous Trades, Sir Thomas conveys to the reader an impression of the beneficent results of State action in industrial affairs; and even the individualist may admit that in many of the problems of the health of workers the universal adoption of measures of improvement is beyond the power of individual effort.

No series of health books, of course, would be complete without a volume on food. Consequently there has been added to this series a volume on *Food: Its Use and Abuse*. It is doubtful how far the healthy individual will feel inclined to read and digest such a manual, and it is arguable whether the unhealthy, and possibly neurotic,

³ *Swanz's Handbook of the Diseases of the Eye and their Treatment*. Edited by Louis Werner, M.B., F.R.C.S.I. Thirteenth edition. London: H. K. Lewis and Co., Ltd. 1925. (Demy 8vo, pp. xv + 693; 276 figures, 9 plates, 21s.)

⁴ *Newer Methods of Ophthalmic Plastic Surgery*. By Edmund B. Spaeth, M.D., F.A.C.S., Major, M.C., U.S.A. Philadelphia: P. B. Kistner's Son and Co. 1925. (Med. 8vo, pp. xxiii + 253; 170 figures.)

⁵ The Modern Health Books. Edited by Professor D. Fraser Harris, M.D. Vol. 4, *The Health of the Workers*. By Sir Thomas Oliver, M.A., M.D., D.Sc., LL.B., D.Ch., F.R.C.P. Vol. 5, *Food: Its Use and Abuse*. By Kate Platt, M.D., B.S. London: Faber and Gwyer, Ltd. (The Scientific Press). 1925. (Fcap. 8vo: Vol. 4, pp. 224; Vol. 5, pp. 232. 2s. 6d. each volume.)

person will benefit by its perusal. But if such books are, in the circumstances, necessary, it may be said that Dr. Kate Platt has produced something which is readable, reasonable, and unprejudiced. For example, although she has a chapter on vitamins, she does not allow her imagination to run away with her reason. She adopts instead the attitude of the late Professor Michael Foster on many physiological questions, that "the matter is not yet ripe for dogmatic statement." Similarly restrained is Dr. Platt's chapter on alcohol; and in the chapter on food systems and food fads, while admitting that some individual may suddenly find that a special system of diet suits him admirably at a particular time, or even permanently, she points out that when he imagines that what is good for him is good for everyone he becomes a food faddist. Possibly many people will incline to the view, within limits, of the lady patient who held that "what the stomach fancies, that the stomach can digest."

Dr. PALFREY, who is instructor in medicine at Harvard University, divides textbooks on medical treatment into those of high authority but of too great size, and those which are condensed for student use, but are of less authority and reliability. In his *Art of Medical Treatment** Dr. Palfrey tries to combine the merits of both classes of book. The chief novelty in the author's method of dealing with his subject is the introduction, at the end of each description of the treatment of a disease, of a paragraph indicating the information which may be given to a patient and his friends. To combat unreasonable excesses of sensation and emotion, says Dr. Palfrey, Christian Science and other methods of inclining the subconscious mind to optimism have arisen. Spartan courage and Christian faith also protect from mental exaggerations. Regret is expressed that in the treatment of neurasthenia visits of the clergyman, more customary in past generations, are now less in vogue. Under the title "Information" Dr. Palfrey gives hints upon which the psycho management of patients and their friends may be based. To combat the tendency of the chronic invalid to resort to quacks and to the professors of cults, it is suggested that medicine must obtain greater command over non-fatal disorders, which are vaguely classed as "myalgias" and "neuroses"; and that the public must be given a clearer insight into the general facts of medical science. In describing treatment diseases are divided into septic infections, diseases due to physical agents or poisons, diseases of nutrition and metabolism, and diseases of various tracts or systems. Synoptic studies of this kind make somewhat uninteresting reading; but the treatment suggested seems to be on sound and common-sense lines.

THE CHEMISTRY OF COLLOIDS.

Dr. EMIL HATSCHEK's *Introduction to the Physics and Chemistry of Colloids* was, when it appeared in 1913, one of the first textbooks in the English language dealing with this subject, and it is pleasant to note that his book has retained its well deserved popularity and has now reached its fifth edition.[†]

The text of the present edition is substantially that of the fourth edition, which was reviewed in these columns four years ago (March 18th, 1922, p. 442), but the book has been revised and various important recent advances in the subject have been incorporated. This work has such a well established reputation that it is unnecessary to say more than that the present edition has been brought completely up to date and that the book remains the best introduction in English to the difficult subject with which it deals.

The second of a series of monographs on colloidal problems, which are being prepared under the editorship of Professor R. Zsigmondy, deals with colloidal gold in biology and

medicine.[‡] It is by Dr. ERNST JOEL, and discusses in an exhaustive manner the properties of colloidal gold, and especially the conditions determining the precipitation of gold sols by proteins. A full account is given of all the factors influencing the gold sol reaction with the cerebro-spinal fluid. In an introduction Professor Zsigmondy states that Joel's researches provide a basis for a rational interpretation of the reactions between gold sol and gelatin globulins, and other hydrophilic colloids; hitherto these reactions have appeared to be extremely contradictory. The researches described are of considerable theoretical interest, and also should prove of direct practical value in rendering less variable the results obtained with the gold sol reaction, when this is used for clinical diagnosis. The monograph concludes with six pages of references to the literature of the subject.

THE NATURE OF TUMOUR FORMATION.

THE Erasmus Wilson lectures which Dr. G. W. NICHOLSON delivered before the Royal College of Surgeons of England last spring have been published in a little book entitled *The Nature of Tumour Formation*.[§] They will provide pleasant reading to all who are surfeited with the rich fare of cancer discoveries, for here is a pathologist who provides explanations and does not presume to offer causes, who doubts whether there is any one cause of tumours. His main theme is that tumours are essentially malformations, and that these arise in healthy tissues. Excessive growth, and therefore tumour formation, is one of the physiological potencies of every healthy cell. It finds its scientific explanation in a change of environment.

The book consists of an introduction, three chapters, and an appendix. The first chapter is on the structure and functions of tumours, and contains observations on various tumours which lead up to the opinion that the structure and behaviour of tumours indicate that they are parts of the tissues of the body, and cannot be separated from them upon anatomical or physiological grounds. The second chapter deals with tissue malformations and their relation to tumours. Dr. Nicholson considers that tumours cannot be separated from malformations; both consist of healthy cells, the growth and differentiation of which agree with those of the normal cells of the body. There are, it is true, certain differences, but these are slight, and can be satisfactorily accounted for by changes of environment. The third chapter, on sequence in tumour formation, traces certain sequences of events which appear to end in tumour formation. The appendix contains an interesting discussion of the relationship of Dr. Nicholson's theories to parasitic theories of cancer. Apparently the work of Dr. Gye and Mr. Barnard was published whilst Dr. Nicholson was engaged in writing these pages. At first sight it would seem that the parasitic theory was opposed to Dr. Nicholson's views, but the two points of view are not incompatible, provided they are not pushed to an extreme.

NOTES ON BOOKS.

VARIOUS members of the Institute of Industrial Welfare Workers have contributed to the book *Welfare Work in Industry*,^{||} edited by ELEANOR T. KELLY, which gives a good account of the activities of the welfare department in factories. In the present state of industrial unrest it is refreshing to find that the importance of welfare work is being more and more appreciated both by employers and employees, for nothing offers greater promise of removing distrust than such work. It is no longer necessary to appeal to humanitarian motives in order to stir an employer to a lively interest in the health and contentment of his staff, for he is now familiar with the fact that ill health spells wastage and discontent diminishes production. To provide for the comfort of the factory hand is as essential as oil to

|| *Welfare Work in Industry*. By members of the Institute of Industrial Welfare Workers, edited by Eleanor T. Kelly. London: Sir I. Pitman and Sons, Ltd. 1925. (Demy 8vo, pp. viii + 119. 5s. net.)

the machinery, and the neglect of either leads to friction and expense. This is a short book, easily read from cover to cover in two or three hours. It gives a very clear picture of what needs to be done and how it can be done. Technicalities such as the management of cauteans, the provision of lavatories and cloakrooms, heating, lighting, and ventilation are reserved for an appendix so as not to interrupt the development of the argument. This book will be useful to medical officers of health and all other medical men whose work brings them into contact with factory life.

Dr. J. M. LYNCH and Dr. J. ELSEN, in their book *Tumors of the Colon and Rectum*,¹¹ set out plainly what is at present known of the pathology of these new growths and give a reliable account of the best modern means of diagnosis and treatment. The fact that so many cases of cancer of the rectum are inoperable when the patients first present themselves at hospital shows the need for well expressed descriptions of the early signs of disease. The authors—one the surgical director and the other the pathologist of the St. Bartholomew's Hospital, New York—seem to have written as much for the general practitioner as for the specialist surgeon. Their book does not contain much information which could not be gathered from standard textbooks of pathology and surgery, and the descriptions of pathological lesions and surgical technique are not so clear as those contained in the special books on the diseases of the lower alimentary canal with which we are familiar in this country. The volume contains 123 illustrations. Those showing the different steps in surgical treatment are good but unnecessarily large. There are more than twenty reproductions of views of cancer seen through a microscope, but all that is represented by these could have been quite well expressed in three or four selected photographs or drawings. Quite half the photographs of gross specimens are likely to remain unsolved mysteries to most readers: they need some device for pointing to the pathological lesion because the photographs have been taken after fixation and distortion of the tissues. We think also that the arrangement adopted of interrupting the text with clinical histories and full-page photographs is not good, because it inconveniences the faithful reader.

Dr. RABAGLIATI of Bradford is a medical Don Quixote. He is possessed with an idea, and he goes forth into the highway to establish it. His pen he wields with much vigour and no little skill, as will be evident to the readers of his book *Human Life and the Body*,¹² of which a new edition has just been issued. His argument is sometimes a little hard to follow, for his enthusiasm causes him to make derivations into physical science, biology, theology, and manifestations of human activity of all sorts. He rejects equally the Miltonic presentation of creation and the theory of evolution. He states that—

"when the time arrived, when all things were now ready for the occurrence of the mutation, the force of man-life appears to have procreated the human form, whether black, yellow or red or white, at all ages and stages simultaneously, specimens of both sexes appearing or arising as old, middle aged, mature, adolescent, juvenile, infantile and unborn simultaneously. . . . Man is the incarnation of anthropino-zoo-dynamic or man-life. Man-life is distinguished from horse-life or hippo-zoo-dynamic."

and so on, for each species, he holds, has its own specific life-force; although "each of these varieties of energy is a manifestation of the one infinite pan-dynamic." He applies the idea to bodily health and to therapeutics. He rejects the common presentation of the body as an internal combustion engine converting foodstuffs into heat and energy. He believes that "the heat of the body is dependent on the force of man-life procreating and inhabiting it, and that food has little if any more use than the replacement of small losses by wastage." He rejects the microbic origins of disease, and his rule of life and of therapeutics is to eat little, for little is needed; if in disease the patient starves the clogged mechanism will be freed once more to function and health will return. We may agree that there is an element of truth in this conclusion without admitting that Dr. Rabagliati's premises are sound.

Dr. S. J. HICKSON, professor of zoology in the University of Manchester, has written a book on *Recent Corals*,¹³ which appears as No. 4 of the Biological Series of the publications of the University of Manchester. In this book, which is lavishly illustrated, Dr. Hickson has given a very interesting

account of the different varieties. Corals excite a universal interest because of their rare beauty. We notice from Dr. Hickson's book that many varieties of coral have been accredited with magical properties, and that some have been recommended as remedies in the treatment of disease.

The increase in the numbers of the medical profession is reflected in the *Medical Register*¹⁴ for 1926, which contains 52,531 names, as compared with 49,858 in the previous issue. During the year 2,569 names were added; in 1924 the additions numbered 2,795. Of the new names in the present issue 1,246 were registered in England, 736 in Scotland, and 406 in Ireland; 175 were colonial and 8 foreign. The number of names removed from the *Register* was 947, as compared with 978 last year; of these 947 the number removed on evidence of death was 794; 146 were removed because of failure to reply to the inquiries of the Registrar as to cessation of practice or change of address, and 6 were struck off the *Register* under the disciplinary powers conferred on the General Medical Council by the Medical Act of 1858.

The forty-second annual issue of *The Year-Book of the Scientific and Learned Societies of Great Britain and Ireland*¹⁵ shows very little change in the general arrangement of its contents. The official returns have been brought up to date, and the book enables all interested in scientific progress to take a bird's-eye view of advances made during the year concerned. In the case of each society a list is given of its officers, places, and dates of meetings, membership conditions, and papers read or published during the year under review. The British Medical Association section occupies four pages, and includes a list of papers communicated to the Sections of the Annual Meeting at Bath.

¹⁵The *Year-Book of the Scientific and Learned Societies of Great Britain and Ireland*. London: C. 1925. (Extra post 6ro, pp. vii + 407. 15s. net.)

PREPARATIONS AND APPLIANCES.

Cholecystography.

In our issue of December 26th, 1925 (p. 1234), we gave some account of two new preparations introduced by Mr. W. Martindale designed to render the gall bladder visible to x-ray examination. The substances are sodium tetrabromophenolphthalein ("bromoray") and sodium tetraiodophenolphthalein ("iodoray"). The method depends on the fact that phenolphthalein and its derivatives are excreted by the liver into the gall bladder, and that bromine and iodine compounds of phenolphthalein are fairly opaque to x rays. The dose of the first was stated to be 2.5 grams in 20 c.cm. of distilled water, and of the other 3 grams in 28 c.cm. of distilled water. Mr. W. Martindale now sends us the following note, which is a further warning against using too large a dose:

"As the use of these compounds is so new, I venture to draw attention to the results recently obtained in America with an average dose of 2.5 grams in 2 per cent. dilution in normal saline (*Journal of the American Medical Association*, January 23rd, 1926, p. 239). The dose and strength is less likely to produce violent reactions than the quantities hitherto employed, and will probably give adequate shadows."

An Improved Stethoscope.

Dr. A. F. G. SPINKS (Newcastle-on-Tyne) writes: The binaural stethoscope shown in the accompanying figure has been designed to give increased comfort and cleanliness when in use. The present custom of using stethoscopes with penetrating earpieces is not a clean one, nor is it free from the risk of infecting the ear passages, as the occurrence of many painful ears among members of the medical profession has proved.

Briefly, the advantages claimed for this new pattern are: (1) It is much more comfortable in use, and especially in prolonged use, than the present patterns with penetrating earpieces. (2) It cannot affect the ears, and the earpieces do not come into contact

with the ear wax, so that it remains always clean. (3) The spring, which is detachable and adjustable, rests on the head, and therefore does not intervene between the eye and the chestpiece, as is the case with most of the present patterns of binaural stethoscopes. (4) The square chestpiece is more comfortable to hold than the prevailing round pattern, and is better adapted for the intercostal spaces.

The stethoscope has been made from my specification by Messrs. Allen and Hanburys, Ltd.

British Medical Journal.

SATURDAY, MARCH 13TH, 1926.

REPORT OF THE ROYAL COMMISSION ON NATIONAL HEALTH INSURANCE.

NATIONAL Health Insurance is a gigantic business—gigantic not only in its own volume, but in the possibilities of its relationship to other national health services and of its effects on national well-being. The existing scheme was in some respects unfortunate in its beginnings. Purely political matters had a disproportionate influence, and a reckless opportunism was not without deleterious effects on its structure. Its authors deserve the credit for vision in conceiving and skill in establishing so great a scheme, and many workers in all spheres connected with it are equally praiseworthy for their success in the difficult task of preventing a breakdown in unexpected conditions, and of securing so large a measure of beneficent effect. It has, however, been manifest for years that the whole scheme was disadvantageously complicated, and that in designing its peculiar machinery and arrangements certain fundamental factors had been forgotten or not properly allowed for—time, migration, occupational change, for instance. Some of the great basic features of the scheme were evidently conceived on the assumption that everyone would do what has to be done approximately at the time it should be done, and that there is a predominant stability in the residence and occupation of insured persons. Without these conditions these features largely lose their usefulness, and have become ill adapted to progressive development. Moreover, the scheme was established without relationship to other health services then existing, and additional health services have since been established without effective relationship with it. Further, it became evident that the financial possibilities of the scheme had been greatly underestimated, and that circumstances had led to the accumulation of balances and of credits much in excess of those anticipated, so that there were vast funds which should, and probably would, have been freely available for national health purposes, if the authors of the scheme had foreseen this result from the first.

Here, then, after thirteen years' experience, was an opportunity for a comprehensive survey of the whole field, and for the exercise of an imaginative vision and constructive ability which might remould the national health services into a really effective and much more orderly and less wasteful form. It should have been possible to discover and set out what are the essential national health services, what additional services are desirable though less essential, which of such services lend themselves to provision on a basis of contributory insurance, how the other services should be best provided and financed, how the administration of all these services should be unified or co-ordinated, how far the work and help of the medical profession as a whole would be needed for these purposes, and what, broadly, are the proper conditions under which the co-operation of the profession could be asked or expected. This opportunity has been missed. Instead, in the Report of the Royal Commission on National Health Insurance there are set out a number of conclusions to indicate that, on the whole, all is well, and a few suggestions for timid amendment which no

doubt, so far as they go, are calculated to produce a certain improvement in the insurance scheme itself. This was, perhaps, to be expected.

It will be remembered that when, about two years ago, the medical profession asked for and secured the appointment of such a Commission, it was promised that the Commission should be impartial and free to report on the whole system, and that when later the names of the members were announced we expressed our disappointment and our doubts, on various grounds which we set out (July 12th, 1924), as to whether a fairly unanimous or broad-minded report could possibly be secured from a Commission so constituted. These fears have been largely justified. To begin with, there is a Minority Report which it was highly desirable to avoid, and, though we may be in agreement with many of the conclusions embodied therein, no one, not even the signatories themselves, would claim that those who sign it constitute a body of persons whose opinion is of any very outstanding weight or value. Again, the timidity so manifest throughout the Majority Report may partly be explained by the evident dominance of official or departmental influences. This is scarcely to be wondered at, seeing that three of the more prominent members of the Commission were themselves, as departmental officials, largely concerned with or responsible for the financial or some other main features of the system under review. Colonel House wrote of President Wilson: "He dodges trouble. Let me put up something to him that is disagreeable, and I have great difficulty in getting him to meet it." The general impression left by the Report is that the Commission acted somewhat like the President. It looks as though it had adopted the plan that any proposal to which any member particularly objected should be dropped. Its unanimity on certain of the proposals is, therefore, all the more satisfactory. By far the most interesting part of the Report is the so-called reservation signed by Sir Andrew Duncan and Professor Gray, but even this, it appears, is submitted merely "to prepare the way for a more fruitful discussion," whereas it might reasonably have been hoped that the Report would embody the fruits of such a discussion.

In these circumstances it is satisfactory to note the general approval expressed of the insurance medical service as such, and to note with agreement the main positive proposals of the Report so far as they affect the medical profession. (1) That financial alterations and adjustments can, and should, be made so as to provide the money necessary to continue at least the present capitation fee for a term of years, and to release additional funds which will allow of some extension of the scope of medical services; (2) that this extension should take the form of the provision of consultant and specialist services and of laboratory services on the general lines laid down by the Association in its evidence; (3) that where an additional treatment benefit is widely adopted the organization and supervision of such benefit should not be in the hands of approved societies, and that negotiations as to any terms and conditions of professional service with regard thereto should be undertaken by the Ministry of Health. The further main proposal that Insurance Committees should be abolished—a proposal on which the Commission is unanimous—has been endorsed by the medical profession only in conjunction with suggestions for substituting an acceptable alternative body or committee. This must be insisted upon, for the alternative proposed by the Report is very vague and tentative. It

is probable that in this matter, as in others, the Commission felt itself handicapped by the fact that the Royal Commission on Local Government was considering an aspect of the general situation which is really inseparable from that which was the subject of its own consideration.

It will doubtless be advisable in the early future to comment further on some of the findings of both the Majority and the Minority Reports; but it may be found on more detailed examination through the proper channels that none of the positive proposals of the Royal Commission need be objected to by the medical profession. The objections are rather to what has not been done, and to the absence of other proposals. Two things are particularly disappointing. One is the painful search for excuses to justify the postponement of any further extension of the scope of benefit, after the very useful discussion under the heads of "Maternity Services" and "Dental Benefit." The other is the unsatisfactory argument and meagre result of the consideration given to the British Medical Association's proposals as to disciplinary procedure on complaints. The statement in paragraph 446 that "the matter was not placed before us by the Association in sufficient detail to enable us to express an opinion" is specially ingenuous, since it was manifest to all the witnesses that they were being heard under a strict time limit and that their examination was both hurried and perfunctory.

The immediate business of the British Medical Association and the profession, in view of the Report, would seem to be (1) to negotiate with the Ministry of Health with regard to further modifications of disciplinary procedure and the principles which should govern it, for this matter cannot be allowed to remain as it is; (2) to negotiate with regard to the methods, terms, and conditions of the proposed specialist service; (3) to formulate carefully, in view of later developments, the proposals the Association may wish to make on those matters which the Commission suggests should be postponed or on which it makes no recommendation.

ADVICE TO MEDICAL STUDENTS.

To a student entering on his professional course and faced with the long list of subjects in which he has to satisfy the examiners it may appear that, especially at the outset, there are a number of obstructions, like bunkers, barring the way to the acquisition of the knowledge which he regards as essential to his real life-work. This failure to see the bearing of, say, physics on physic, to correlate his early studies with his eventual goal, and to realize the educational unity and continuity of the curriculum, is perhaps not unnatural when all things are new, and the immediate aim is to pass examinations and get on with the next subject. Examinations, though necessary for the disciplinary control of the weaker brother, no doubt exert an evil influence on the best students. It is highly desirable that the student should grasp the purpose of the preliminary subjects and the use that a living knowledge of their essential principles will be to him in the later stages of his course, to which he is looking forward with pardonable impatience.

To supply this need Mr. Alexander Miles, who has taught and watched many generations of Edinburgh students, has written a message in simple language, wisely explaining technical terms as he takes the student over his course. In his *Guide to the Study*

of Medicine¹ the scheme of medical education is succinctly summed up under five headings: general education, natural sciences, professional scientific subjects, clinical subjects in relation to the individual, and medicine in relation to the community.

On leaving school the student of medicine should realize that he enters on a new stage in his educational career, and should not, as often happens, continue on the same lines as before. The time has now come to think more for himself, to depend less on his teachers for his deductions, and to form his own independent judgements. It is well that the importance of chemistry, physics, and biology in preparing the way and laying a sound foundation for medical practice should be impressed on the student, who, when he understands this, will turn to these studies with more energy and goodwill than if he imagines they are nothing more than a means of training his powers of observation and reasoning. At no time has the fundamental bearing of chemistry been clearer than in the light of modern medicine, with the phenomenal rise of biochemistry and the study of metabolism, and the era of functional tests. Biology not only leads on to anatomy and physiology, but it lays the foundations of parasitology and bacteriology, and it must be remembered that no clinical problem can be solved except in terms of anatomy, physiology, and pathology. In truth, the clinical subjects have the same claim to be "scientific" as the earlier laboratory courses, and the curriculum is essentially a correlated whole; for to the wards the student should bring the same scientific spirit of inquiry that the earlier work has inculcated.

But beyond what Mr. Miles so thoroughly explains to the student, clinical work has a broader human interest, and deals with fellow men, whose personalities, habits, thoughts, and aims demand attention. In this respect the study of psychology no doubt will help; but this is not all, for in no profession is the motto "*Homo sum; humani nihil a me alienum puto*" more appropriate, and in order to qualify in this respect too it behoves the student, much tried as he is by classes, sore let and hindered by examinations, and therefore with little time to think for himself, to obtain a broad knowledge of the world. Otherwise the increasing demands on his time by the character of his work may narrow the student's horizon and isolate him from all but his fellow slaves, and there is no small risk of his vitality, mental and physical, becoming impaired. Literature, the arts, and healthy exercise must not be sacrificed entirely to work, and, indeed, some time devoted to them will not only benefit the man but improve him as a student of medicine.

PUERPERAL MORTALITY.

THE address, published elsewhere in this issue (p. 469), on puerperal mortality by Sir Ewen Maclean, chairman of the Committee on Causation of Puerperal Morbidity and Mortality, is opportune in that it heralds the completion of the preliminary phase of the Committee's arduous task. The reference to the Committee by the Council of the British Medical Association was "to consider and report on the causation of puerperal morbidity and mortality, and on the administrative action, if any, that should be taken in connexion with the matter." Truly a far-reaching reference, and one which, as the chairman said, may well demand the influence of the Association in initiating research; its unrivalled capacity, through the Divisions,

¹ *A Guide to the Study of Medicine.* By Alexander Miles, M.D., F.R.C.S., LL.D. Edinburgh and London: Oliver and Boyd. 1925. (Cr. 8vo, pp. vii + 92. 3s. net.)

in influencing clinical methods; and its experienced medico-political skill. The Committee has propounded a bacteriological problem to the Medical Research Council. It has urged the intensification of research into the resistance aspect of the problem; and on the basis of the interim report and questionnaire published in the SUPPLEMENT of January 9th last (pp. 13 et seq.) it has established close contact, through the Divisions, with the members of the Association, as is evidenced by the address of Professor Louise McIlroy to the St. Pancras Division, also published in this issue (p. 471). The next phase of the Committee's work will be the analysis of the replies and recommendations of the Divisions; the consideration of these and of the recommendations of the Government reports; and a frank discussion of the whole problem at the joint conference mentioned in the chairman's address (p. 470). The material submitted to the conference and the proceedings thereof will form the basis of a further report to the Council, whose comments and recommendations will come before the Divisions. The discussion which took place at the meeting of the Monmouthshire Division after Sir Ewen Maclean had delivered his address we also publish (p. 477); it illustrates what has been very general in the Division meetings as a whole—namely, the appreciation of the fact that notification is a prominent or even a dominant factor in the administrative side of the problem. Its many difficulties are readily apparent, and the valuable contribution of Dr. Rodyn-Jones to the discussion at the Monmouthshire Division on this point is well worth noting. The further report of the Committee will be awaited with interest, and meanwhile we would remind members that comments and suggestions directed to the Medical Secretary on any of the various aspects of the problem will be welcomed.

THE COURTAULD INSTITUTE OF BIOCHEMISTRY.

MR. SAMUEL AUGUSTINE COURTAULD, who in 1924 endowed the chair of anatomy at the Middlesex Hospital Medical School with the sum of £20,000, has now presented to the hospital £30,000 for the provision of an institute for education and research in biochemistry. It is proposed to erect a seven-story building on a site adjacent to the hospital; it will be placed under the administrative charge of Dr. E. C. Dodds, professor of biochemistry in the University of London. This Courtauld Institute of Biochemistry will be a complete department of medical chemistry, and will be closely associated with the Bland-Sutton Institute of Pathology directed by Professor James Mackintosh. It will thus be possible to co-ordinate research in physiological and pathological chemistry, and it is not easy to overestimate the benefits that may accrue to the hospital and to humanity from this generous gift, which springs from the donor's recognition of the importance in preventive medicine of systematic and co-ordinated research. Our knowledge of the chemistry of living tissues, though very imperfect, has yet been rapidly extended during recent years, thanks to systematic research, with the result that the conditions of health and disease are now much better understood, while new and potent remedies have been added to the pharmacopoeia of the clinician. New vistas of research have opened. The dream of isolating the important internal secretions which play so large a part in human life is now approaching realization, and, following the acquisition of accurate knowledge about their chemical nature and the conditions of their activity, their synthetic preparation may be expected. An even more pressing need of the moment is the creation of some system of standardization for the various organic preparations now on the market, and this is already the subject of intensive research. Chemotherapeutical investigations provide another vast field from which great practical results may be expected. With

abundance of clinical material for study, with the obligation of teaching students, combined with the duty of acquiring new knowledge, the institute will occupy a most favourable position for its own work, and should itself supply a great stimulus to research elsewhere. Since medicine now looks to biochemistry to solve some of its most difficult problems, the medical profession as a whole is deeply indebted to Mr. Courtauld for his wisely guided generosity. Congratulations are due also to the Middlesex Hospital, where previous devotion to practical research has prepared the way for the Courtauld Institute to realize to the full its possibilities.

SIR CHARLES BELL.

THE work of Sir Charles Bell in relation to modern neurology formed the subject of Dr. H. Campbell Thomson's presidential address to the Section of Neurology of the Royal Society of Medicine in October last, and the address has now been published in *Brain* (December, 1925). To Sir Charles Bell belongs the credit of discovering the difference in function between the anterior and posterior spinal nerve roots, an event the importance of which has been compared with Harvey's discovery of the circulation. When Bell started his experiments on the spinal roots about 1810, little advance in knowledge of nerve physiology had taken place since the time of Galen. Bell was primarily an anatomist, but, not satisfied with demonstrating the structure and relations of the nerve roots, he attempted to determine their functions by section and by galvanic stimulation. He established clearly the motor character of the anterior roots, and showed the probable sensory function of the posterior. The observations had an even wider significance than demonstrating the functions of the roots, as they led to further experiments on the cranial nerves and to the enunciation of the general principle of the specificity of function of nerves. Experiments similar to Bell's were carried out independently by Magendie, and their names are associated as authors of this important law, the general truth of which remains unchallenged as one of the principles of neurology. Bell recognized that the specific action of a nerve does not depend upon the structure of the nerve itself, but upon the end organs with which the nerve is connected and upon the central connections of the nerve. Thus, while the optic nerve normally conveys light impulses only from the retina, stimulation of the nerve in its course by any other means gives rise to a sensation of light because of the central connexions of the nerve. Further illustrations of the fact that it is not the nerve fibres themselves which are specific in function have been found in the results of operations of transplantation of the peripheral end of one nerve into the central end of another—for example, the successful grafting of the facial nerve into the central end of the spinal accessory for the cure of facial paralysis. Minor exceptions to the Bell-Magendie law respecting the spinal roots have been discovered in recent years—for example, the demonstration by Bayliss of vaso-dilator fibres in the posterior roots conveying impulses peripherally from the spinal cord to the skin (that is, in the opposite direction to the sensory impulses). Another apparent deviation from the law is suggested by the occasional failure of posterior root section to cure the lightning pains and gastric crises of tabes dorsalis; the suggestion from this failure is that some sensory impulses must reach the cord through the anterior roots. Dr. Campbell Thomson mentions other examples of Bell's observations on the nervous system which show the breadth of thought by which he anticipated truths which have later been confirmed. He observed the retention of certain involuntary movements on the paralysed side in cases of hemiplegia, anticipating the fact of the bilateral representation in the cortex of certain movements—for example, those associated with respiration. He recognized

the existence of sensory impulses from muscles giving a knowledge of the state of muscle contraction—in other words, the existence of muscle sense. Perhaps most remarkable of all was his recognition of the phenomenon of inhibition—namely, that the action of a nerve may be to cause a diminution or cessation of activity in the structure supplied. He thus anticipated the principle which was later exemplified by the Webers in the inhibitory action of the vagus on the heart. Bell further found that contraction of a muscle was accompanied by relaxation of opposing muscles, foreshadowing the law of reciprocal innervation of muscles which Sherrington showed to be of such importance in reflex and voluntary movements. Bell was elected surgeon to the Middlesex Hospital in 1814, and was the founder of the medical school of that hospital; in 1835 he was appointed to the chair of surgery in the University of Edinburgh. The second article in the issue of *Brain* for December, 1925, describes a careful study of the morphology of the Gasserian ganglion carried out by Dr. Edward Whitehead in the Carnegie Laboratory of Embryology, Baltimore, Maryland. In an introduction Dr. Charles H. Frazier describes the object of the investigation, which was mainly to give a scientific basis to the operation of subtotal resection of the sensory root for trigeminal neuralgia. Dr. Frazier has performed section of the sensory root 396 times, and during the past ten years in 25 selected cases has modified the operation by leaving undivided the two inner fasciculi of the sensory root; the motor root was, of course, isolated primarily in all the cases. In no instance did keratitis or recurrence of pain follow upon this operation. This successful result suggested that the Gasserian ganglion must be anatomically and physiologically not a single but several distinct units, representing respectively the ophthalmic, maxillary, and mandibular portions. Dr. Whitehead's investigations show that the ophthalmic division is early differentiated from the others by its precocious development, and the site of development of the ophthalmic nerve is widely separated from that of the maxillary and mandibular nerves, which are close together. The fibres from the ophthalmic division remain differentiated from the others in the sensory root, and there is no tendency for the fibres to intermingle.

SURVIVAL AFTER GASTRECTOMY FOR CANCER.

DR. GEORGES HAYEM has recently reported the case of a patient who lived for more than twenty-seven years after resection of the stomach for cancer.¹ The operation was performed in 1898, the patient being at that time 41 years of age. Every succeeding year the patient wrote to his surgeon with praiseworthy but unusual fidelity, till in the year 1925 no letter arrived from this punctual correspondent. Inquiries were made, and it was found that he had died of pneumonia in a provincial hospital. Here certainly, as Dr. Hayem remarks, was a definite case of surgical cure of cancer of the stomach. This interesting story appears to have directed attention to the question of survival after gastrectomy for cancer, and in the next number of the *Bulletin*² Dr. Henri Hartmann describes the results of a statistical inquiry. Out of 100 patients operated on for gastric cancer 35 survived one year or more afterwards, and of these 35, 28 passed the three-year period without recurrence. Taking a period of three years' survival as evidence of cure, it seems from this series that about 30 per cent. of the patients were cured by their operation. It is interesting to compare this series of cases with the results of surgeons in this country. James Sherren, in Choyce's *System of Surgery*, gives an account of 84 patients on whom partial gastrectomy was performed, with 6 deaths, and adds that at the present time the mortality should not

exceed 10 per cent. Of his cases, 21 remained free from recurrence for more than three years after operation; 3 after more than ten; 4 more than six; while 1 died of another disease seven years later. The average duration of life after partial gastrectomy in cases with recurrences is about eighteen months. Recurrence is rare after two years, and if life is prolonged beyond four years there is good prospect of cure. From the collected statistics of H. J. Paterson,³ it appears that 15 per cent. of the patients operated upon lived five years or more. In 140 resections of the stomach for carcinoma reported by Kocher (1910) 20 per cent. remained well for over four years. Returning to Dr. Hartmann's communication to the Académie de Médecine, he makes some observations which deserve brief mention. He found that it was exceptional for recurrence of cancer to appear after the second year. No relation was traceable between the histological characters of the tumour and the likelihood of recurrence, nor did the presence or absence of free HCl before the operation seem to have any bearing on the after-history of the case. He believes, however, that the technique of the operation is more concerned in the case mortality than was formerly realized, and in particular he refers to the danger of implanting cancer cells in neighbouring organs at the time of operation. He concludes by insisting on the importance of early diagnosis and operation if recurrence is to be still further diminished.

ARTIFICIAL LIGHT CLINICS IN GLASGOW.

TREATMENT of tuberculosis, rickets, and malnutrition in children by ultra-violet rays is now being carried out at several centres in Glasgow, and a report on the methods employed has recently been issued by the public health department. Dr. Alexander Smith, who reports on artificial sunlight therapy at Robroyston Sanatorium, gives a good description of how a clinic can be organized and of the results which can be expected. "The fitful appearance of the sun and the relatively weak actinic value of its rays" is given as a reason why in northern countries heliotherapy is difficult to carry out and resort must be made to artificial sources of ultra-violet rays. He might have added that the cloud of smoke which overhangs the city robs the citizens of a good percentage of the rays the sun intended for them. The clinic at Robroyston is an indoor one, and mercury vapour lamps of 20 to 75 amperes are employed. Eight sitting patients can be grouped round the two 75-ampere lamps, while two recumbent or from four to six sitting patients can be irradiated by the three 20-ampere lamps. The treatment given consists of general irradiation, the patients being entirely naked save for very short pants. They sit at a distance of about 1 metre on either side of the lamps, which are not covered by glass. The initial exposure is usually of twenty minutes or less, the patients being instructed to turn every five minutes, so that the back and front are alternately exposed. Every fourth day an additional exposure of five minutes is given, until a maximum of two or two and a half hours is reached. All ambulant patients, save where there are special contraindications, receive a tepid to cold spray on emerging from the light room. Bed patients are sponged down by the nurse, a procedure which, apart from its tonic effects, prevents the patients from catching cold. Up to the present 102 patients have been treated, chiefly cases of lupus and tuberculosis of the glands, joints, bones, and lungs. Dr. Smith remarks that one of the most striking features of the treatment is the rapid improvement in general health. Flabby muscles soon gain in tone, and the muscular atrophy which is such a common feature around tuberculous joints is not nearly so noticeable as in patients

¹ *Bulletin de l'Académie de Médecine*, January 11th, 1926.
² *Ibid.*, January 18th, 1926.

³ *BRITISH MEDICAL JOURNAL*, 1910, vol. ii, p. 953.

who receive the ordinary treatment without generalized light baths. In only two or three cases did they fail to show a steady gain in body weight. Turning to the effects of the treatment on different tuberculous lesions, we note that 13 cases of lupus have been treated, most of them of an extensive nature and of long duration. Carbon dioxide snow, sulphanilic picric acid, x rays, etc., had previously been used without avail. All but three patients have shown very remarkable improvement, and 6 have been dismissed as cured. Twenty-three cases of glandular tuberculosis, mostly cervical, have been treated. Of these, 18 had sinuses and surrounding scrofulous ulcers; 2 were complicated by abscess formation; and 2, though extensive, had not broken down. In all improvement has resulted. In the sinus cases healing has been rapid, the scars firm and elastic, and puckering and contraction of tissue have been less noticeable than when ordinary routine measures were adopted. Excellent results were obtained also in tuberculosis of the elbow, ankle, and wrist. In tuberculosis of the lungs light therapy must be used cautiously. The 10 cases selected for treatment are reported as gaining in weight and improving in general condition, but sufficient time has not yet elapsed to allow of a prediction of the ultimate results. The report published by the Glasgow public health department contains accounts of work done in four other centres in the city, and in these too it appears that very useful work is being done with different forms of artificial light and x-ray treatment.

INDUSTRIAL PSYCHOLOGY.

IN a recent lecture delivered by Dr. C. S. Myers, director of the National Institute of Industrial Psychology, under the auspices of the Jewish Health Organization, an interesting survey of the development of this science was given. One department of "vocational guidance" was concerned with careful physical and mental examination of young people choosing careers, and another department dealt with the selection of the right person for a vacancy. Such scientific procedure eliminated a considerable amount of discontent and loss of time and money, both as regards employers and employees. Dr. Myers pointed out the error involved in omitting tests of practical intelligence and relying only upon mental ability. In dressmaking, for instance, speed, accuracy, power of observation and of design, and ability to carry out instructions, were necessary. In Germany ingenious methods of testing imperviousness to distraction had been introduced, the candidate being required to do several things simultaneously, so that the co-ordination might be tested. France and Germany were both using tests for motor-car drivers, with valuable results as regards saving of life, time, and energy; these tests had not yet been adopted in this country. The lecturer remarked that many industries in this country, such as engineering, weaving, glass-blowing, and dressmaking, had, however, developed psychological tests, and in Manchester and Glasgow great use was made of tests for capacity in assembling mechanical parts. Again, an investigation of breakages in certain catering establishments showed that these were due to psychological causes, and reduction followed attempts to make the danger points "foolproof." Dr. Myers explained how the total output was increased by the adoption of shorter hours of work, and benefited the industry as a whole. The drop in the afternoon and evening output of a ten-hour plant was greater than in an eight-hour plant. The real output of an industry increased from Monday to Wednesday, then fell from Thursday to Saturday, when the drop was so great that many factories found it advantageous to close for the whole of Saturday and to use that day for putting the place in order. The inexperienced worker became more tired than the expert one,

and his output declined more rapidly after Wednesday than did that of an efficient employee. Curves showed that forty hours a week seemed to be the average at which the best hourly output could be obtained: fewer or more hours led to a decline. The seasons also played a large part in output, more work being done in summer than in winter. Industrial psychology was not endeavouring to speed up work; its aim was to detect the difficulties, both physical and mental, which confronted the worker; when these were removed output was automatically increased, leaving the worker less tired and more able to give his best. By improving the illumination of certain mines the output had been increased by 12 per cent., and by studying physical movements an increase of 16 per cent. had been obtained, many valuable suggestions being received from the miners themselves. The National Institute of Industrial Psychology had been enabled by the Carnegie Fund to give vocational guidance in the King's Cross area to 600 children, whose careers would be followed and compared with those of 600 children apprenticed without such care.

THE OPIUM EVIL IN INDIA.

IN a booklet of sixty-three pages issued by the Student Christian Movement, entitled *The Opium Evil in India: Britain's Responsibility*,¹ Mr. C. F. Andrews essays to show "the true extent of the opium evil for which the Government of India must be held responsible." From personal investigations in the chief cities of India, in Assam, and in Burma, Mr. Andrews is led to conclude that in industrial centres there is a growing addiction to the use of "Government monopoly opium." Assuming the League of Nations figure of 12 lb. per 10,000 of population as representing the medical and legitimate amount of the drug required, he finds the quantity consumed in Bombay to reach 88 lb., in Rangoon 216 lb., and in Calcutta 288 lb. per 10,000. The doping of children with opium pills by mothers working in cotton mills is said to be unduly prevalent. In Assam, with a population largely of Mongolian origin, the consumption of opium was also excessive until the non-co-operation campaign of Mahatma Gandhi effected, it is claimed, a marked reduction in the consumption of the drug if not in the revenue derived from it. The justification of the Assam Government's opium policy attempted by the district officer, Mr. Cosgrave, in a recent speech to the Legislative Assembly at Delhi, appears to have been discounted by the evils attributed by the civil surgeon of the same district to the opium-eating habits of its people. Unlike Assam, the consumption of opium in Burma is mainly by way of smoking, and although a system of registration of existing addicts with a view to eventual prohibition was inaugurated, this appears to have broken down owing to the open sales still allowed to others than Burmese. Lastly, the continued export of Indian Government opium to the Far East, well knowing that it is to be used for smoking, is severely criticized as being in contravention of the spirit, if not of the letter, of the Hague Convention. This policy was defended at the recent Geneva conferences by Mr. (now Sir) John Campbell and Lord Cecil. That this should have been the case is the more remarkable in the light of the new policy just announced by the Government of India, whereby exports of opium, except for strictly medical purposes, are to be annually reduced and finally extinguished. The Assam Opium Inquiry² was undertaken at the instance of the All-India Congress Committee with the assistance of Mr. C. F.

¹ *The Opium Evil in India: Britain's Responsibility*. By C. F. Andrews. London: Student Christian Movement. 1925. (Cr. 8vo, pp. 63; 1 map. 1s. net.)

² *Assam Congress Opium Inquiry Report*. September, 1925. Santiniketan, Bolpur, Bengal: C. F. Andrews; London: Student Christian Movement. 1925. (64 x 91, pp. 165; 1 map. 2s. post free.)

Andrews. It traces the opium habit to its introduction into Assam by Rajput troops in 1794. The habit became widely diffused and firmly established. There were in 1873-74 some 5,000 opium shops in the province; and in the district of Lakhimpur the consumption amounted to 378 lb. per 10,000 of the population. The report suggests that the opium habit is by no means as innocuous as it has been represented, and that opium smoking is practised in other parts of India as well as in Burma. The committee of inquiry frankly admits its political sympathy with the non-co-operation movement, and attributes the reduction in opium consumption since 1921 to the influence and teaching of Mahatma Gandhi. These two works support the view, which resolutions passed not only by the National Congress but also by the Assembly at Delhi confirm, that native opinion in India is hostile to the official opium policy as formulated by the Royal Commission of 1893-95; and it would seem that by the recent pronouncement of a change of policy the Indian Government is making a virtue of necessity.

BIOLOGY IN SHAKESPEARE.

PROFESSOR FRASER HARRIS, M.D., D.Sc., formerly lecturer on physiology at the University of Birmingham, and afterwards professor of that subject at the Dalhousie University, Halifax, Nova Scotia, delivered the last of a series of Monday evening lectures at the Midland Institute on March 8th. His subject was "Biology in Shakespeare," and he explained that he used the word "biology" as meaning all knowledge concerning life, vegetable and animal, both in health and disease. For the purposes of the lecture he would not study any references to botany, zoology, or medicine. He did, however, include one or two allusions to surgery, the most interesting of which were the lines spoken by the Archbishop of York in *Henry IV*:

"If we do now make our atonement well,
Our peace will, like a broken limb united,
Grow stronger for the breaking."

References to the physiology of the following were studied in the plays: sleep, the heart, arteries, veins, and nerves; fainting, the doctrine of the three kinds of spirits, the *halitus sanguinis*, the action of alcohol, digestion, starvation, the description of Falstaff's death, infection, first aid, the *vis medicatrix naturae*, the pia mater, and the visceral distribution of the emotions. Professor Fraser Harris discussed also the physiological psychology of visual hallucination, trophism of nerves, sense before motion, retinal fatigue, the Sanson images, giddiness, psychical blindness, and paraphasia. His most interesting lecture closed with a detailed analysis of all that is implied in the lines in *Hamlet*:

"The glow-worm shows the matin to be near,
And 'gins to pale his uneffectual fire."

THE CAPACITY OF CHILDREN TO UNDERSTAND LANGUAGES.

A SHORT article on the intuitive capacity of children to understand spoken language, from the pen of Dr. J. W. Tomb, was published last year in the *British Journal of Psychology*. It gives the writer's experience of English infants in India between the ages of 9 and 18 months, whom he found could receive instructions and directions from their mothers in English, from their ayahs in Bengali, from the house servants in Hindustani, and so on, before they are able to speak any of these languages themselves. Again, English children of 3 or 4 years of age conversed freely with their parents in English, and with servants of different types in Bengali, Santali, and Hindustani. This facility for speaking and understanding several languages

or dialects is contrasted with the labour expended and difficulty experienced by adults in acquiring them; and the author states that the facts can only be satisfactorily explained on the hypothesis that children possess the capacity of intuitively placing the correct meanings on spoken sounds, a capacity which they retain up to a certain age, but, in the majority of instances, lose altogether as they approach adult life. This is no doubt true; but would it not be equally true of adults who set themselves to acquire a limited knowledge of a language by sound only instead of by the laborious method of studying grammars and printed books? After all, the vocabulary an infant acquires is extremely limited, and in the acquisition of the meaning of words the child is greatly assisted by the gestures and repetitions of parent, nurse, or servant, all of whom conspire to be his teacher. Had an adult the same method of acquiring an equally limited vocabulary the chances are that he would learn it much more rapidly than the infant. Children learn mainly by imitation; their minds are more receptive, and more insistent in expressing themselves in words than is the case with adults, who have many other occupations and distractions and less time or desire to pay attention to the acquisition of the language of any foreign country in which they may happen to be living. Although the subject, therefore, of the difference between the capacity of children and that of adults to speak and understand languages of their environment is of considerable interest, the cause of the difference does not seem to rest on any deep or obscure psychological basis, but to depend more on imitation than on the intuition suggested by Dr. Tomb. Remove the child from the environment of the language which was learnt by imitation, and the memory of it is gradually lost, whereas the adult who has learnt a language by concentration of effort retains a memory of it over a long period of time.

OXFORD OPHTHALMOLOGICAL CONGRESS.

THE Oxford Ophthalmological Congress will be held on Thursday, July 15th, and two following days. On the first day a discussion on sympathetic ophthalmia will be opened by Mr. Malcolm Hepburn, surgeon to the Royal London Ophthalmic Hospital, followed by Mr. S. H. Browning, bacteriologist to that hospital, and Dr. T. Harrison Butler, surgeon to the Birmingham and Midland Eye Hospital. The Doane Memorial Lecture will be delivered on Friday, July 16th, by Dr. Thomson Henderson, surgeon to the Nottingham and Midland Eye Hospital. The subject of the lecture is the anatomy and physiology of accommodation in mammalia. It is proposed to devote one afternoon entirely to demonstrations in the scientific and commercial museums of the Congress, and members are invited to bring novelties of any kind—pathological specimens, operations, or apparatus. It is asked that those who desire to contribute papers or demonstrations, or to take part in the discussions, will notify the honorary secretary, Mr. Bernard Cridland, Salisbury House, Wolverhampton, as early as possible. The members will assemble at Keble College on the evening of Wednesday, July 14th, and the official dinner of the Congress will take place on the evening of Thursday, July 15th, in the hall of that college.

MAJOR-GENERAL T. H. SYMONS, C.S.I., has been appointed Director-General of the Indian Medical Service in succession to Sir Charles Macwatt, who has held the office since 1922. Major-General Symons, who received his medical education at Charing Cross Hospital, where he was house-surgeon, house-physician, and resident obstetric officer, entered the I.M.S. in 1896. He was appointed surgeon-general with the Government of Madras a little over two years ago.

Canada.

[FROM OUR SPECIAL CORRESPONDENT.]

HOSPITALS IN MONTREAL.

THE financial position of the hospitals in Montreal, and to some extent throughout the Province of Quebec, has been the subject of much public discussion. It has been maintained that the cost of caring for indigent patients is being borne in too large proportion by private charity, with the result that such a large city hospital as the Montreal General Hospital is faced each year with a large deficit. The arrangement at present is that the cost of such patients is divided equally between the Provincial Government, the city of Montreal (in the case of its own hospitals), and the hospital—that is, private charity. The daily cost, which so far has been placed at two dollars a patient, is now declared to have risen to three dollars, but the amounts paid by the Government and municipality have not been increased, with the result that private charity has been making up the difference. The Government has therefore been requested to pay for each indigent patient at the rate of two dollars, instead of 1.34 dollars. Another matter which adds to the burden of the hospitals in Montreal is the caring for indigent immigrants. This city has an especially large floating population, not only because its size attracts many, but also because it is directly in the path of the stream of immigration. Many of these people find their way into the public wards, but few can afford to pay for their treatment. The cost in such cases falls entirely on the hospitals, since the municipal allowance only covers citizens, and the definition of citizenship is quite rigidly defined. It has been suggested that this particular problem be handled by the Department of Immigration and Colonization. The position taken by the Provincial Government in the face of these demands is that of sympathetic consideration, which so far, however, has not produced anything more concrete than the statement that the Government is quite willing to listen to proposals for the raising of the necessary funds for the extra expenditure called for. There has, by the way, been a request also that an allowance be made for outdoor patients of 35 cents per treatment. It has been suggested that the money be raised in various ways, such as by increasing the price of alcoholic beverages (the sale of which is under Provincial control), or by placing a small tax on automobiles. Neither of these proposals has been received with favour, since it is felt that the excise duty on alcohol is already very high, and that there is no reason why the owner of a car should be singled out for the support of the hospital, especially as he probably pays for his own treatment therein. Still, the problem is being freely discussed, and a general petition is being circulated for signatures, requesting the Government to formulate some special small tax to meet the needs of the situation.

DR. FRANCIS J. SHEPHERD.

A portrait of Francis J. Shepherd, M.D., LL.D., F.R.C.S. Eng. and Edin., has recently been presented to McGill University, and has been placed in the assembly hall of the medical building among the portraits of other men who have helped to build up the medical faculty of McGill. The portrait was subscribed for by the medical faculty and by students and house-men who worked under Dr. Shepherd. The presentation was formally made by Dr. F. G. Finley, who recalled Dr. Shepherd's long and brilliant career. He had been not only a great surgeon, but also a great teacher of anatomy, and it was through his unceasing labours that the department of anatomy at McGill University had been built up into what it was. He had, too, the instinct of a true collector, and had brought together a splendid anatomical museum, but this, unfortunately, had been lost in the fire which destroyed the old medical building. He had seen surgery in the pre-antiseptic days, and had been the first to give up the carbolic acid spray and to do away with elaborate moist dressings. His reputation as a dermatologist was also very high, and was another instance of width of interests. The

portrait (painted by Miss G. DesClayes) was received for the university by Dr. Charles F. Martin, dean of the medical faculty, who said that it would serve as an inspiration and a symbol of what a man of wide culture and attainments might become. Dr. Shepherd, who has for some years retired from active teaching and work, spoke in appreciation of the honour done him, and of the signs of respect and affection shown him by those whom he had taught and who had worked with him.

MEDICAL LEGISLATION IN ALBERTA.

The Provincial Legislature is considering a bill which vitally concerns medical affairs. One of its provisions is the appointment of an appeal board of laymen who will deal with disciplinary questions of the medical, legal, and dental professions which have been adjudicated upon by the administrative bodies, or any of these organizations in which appeal is asked for. The decision of the board is to be final, and will do away with a Supreme Court action. Another provision is that any physician styling himself a "specialist" in any branch of medicine or surgery will have to substantiate his claims. Attempts will also be made to curtail the number of operations and to prevent fee-splitting. The radical nature of these proposals suggests that they have about them an element of political tactics, and they are being discussed with a warmth that ensures that they will meet with a good deal of opposition.

Scotland.

REGISTRAR-GENERAL'S REPORT FOR SCOTLAND.

THE vital statistics of Scotland for the fourth quarter of 1925 have just been published. An examination of the annual figures shows a low and falling birth rate, a low marriage rate, and a low death rate. The birth rate of the year was 21.3 per 1,000, the marriage rate 6.6, and the death rate 13.4. The deaths among children less than 1 year of age numbered 9,429, and as the registered number of births during the year was 104,137, these deaths equal an infantile mortality rate of 91 per 1,000. This rate is 7 less than in 1924, but 12 more than in 1923; it is 8 less than the mean of those of the preceding ten years. During the year 1925 there were registered in Scotland the deaths of 65,505 persons, a number 4,852 fewer than in all years from 1862 to 1922, with the exception of those in 1923, which they exceeded by 2,222. The death rate of 13.4 per 1,000 is 1.0 per 1,000 less than that of the previous year, but is 0.5 more than that of 1923. This is the third year in which a Scottish annual death rate of less than 14 per 1,000 has been recorded, the two previous years being 1921 and 1923. The principal epidemic diseases produced a death rate for the year of 0.84 per 1,000, being 0.17 less than that of the previous year, 0.15 less than the mean of the five preceding years, and 0.26 less than the mean of the preceding ten years. The death rate from tuberculosis of the respiratory system was 76 per 100,000 and from all forms of tuberculosis 110. The former rate is 4 less and the latter rate 6 less than in the previous year. Both these rates are the lowest yet recorded from tuberculosis. The principal epidemic diseases produced death rates varying from 1.70 in Dundee, 1.36 in Coatbridge, 1.18 in Edinburgh, and 1.14 in Glasgow, to 0.38 in Kirkcaldy and in Ayr and 0.61 in Dunfermline. Deaths from influenza numbered approximately half what they did in the previous year, deaths from cancer showed an increase of 175, the figure being 5,673 as against 5,498 in the previous year, and the number is the largest yet recorded in any one year. Deaths from tuberculosis of the respiratory system numbered 3,733, which is the smallest number yet recorded. Deaths from encephalitis lethargica numbered 154, which is 27 fewer than in the previous year, and those from cerebro-spinal meningitis numbered 83, which is 4 fewer than in the previous year. In regard to the causes of death during the last quarter of 1925 as compared with the preceding quarter, deaths from scarlet fever were 56 more, from diphtheria 76 more, and from measles 110 more. Deaths from influenza during the

quarter numbered 293 as compared with 90 in the previous quarter, and with 509 in the fourth quarter of the previous year. Deaths from pneumonia, exclusive of those associated with influenza, numbered 1,935 during the quarter, constituting 10.9 per cent. of the total deaths and equalling a death rate of 157 per 100,000.

THE MORISON LECTURES.

The first of the Morison Lectures for 1926 was delivered by Dr. R. D. Clarkson, F.R.C.P.Ed., in the Hall of the Royal College of Physicians, Edinburgh, on March 1st. Professor George M. Robertson, President of the College, occupied the chair. The lecturer took as his subject mental deficiency, and in the first lecture dealt with the definition of mental deficiency and with the classification of mental defectives. In this he followed Tredgold's system. In the second lecture Dr. Clarkson considered the causes of mental deficiency. The microcephalic type, which was not common, might be divided into cases in which an excessively small head was due to a defect of large areas of the brain, and into cases with small head and large face, sloping forehead and simple brain with unusually small cerebral hemispheres, which was supposed to be a reversion to an ancient prehistoric type of ancestor. The mongolian type was responsible for about 5 per cent. of cases in institutions, but this did not represent the true proportion, because most of this type of defectives were of an affectionate, lovable type, who were not sent to institutions; moreover, they died early. The cause of this type was not known; the prevailing idea that they generally formed the last member of a large family was not always true. Defect of various endocrine glands had been blamed, but the fact remained that no effect had been obtained from treatment by extract of any gland. The condition was certainly not syphilitic, but there were often bodily defects, such as congenital heart abnormalities. The simple primary type of amentia had been supposed from the time of Morel to be hereditary, such children being the offspring of mentally defective parents. The lecturer made a strong protest against this prevailing view; he had only been able to discover 6 out of 3,500 cases in which the parents of mentally defective children had been certified or certifiable as mental defectives. He believed there was a certain amount of confusion in regard to primary simple mental defect as to what was meant by hereditary and congenital influences respectively. Environment was just as important, and he attributed considerable influence to the effect of alcohol in regard to mothers who were soaked in it during the period of pregnancy. He also thought that there was some evidence for what might be termed the operation of incompatibility between the male and female germ plasma. The theory of heredity had been largely based upon certain well known and, in some cases, appalling family histories. The lecturer criticized these records, and quoted statements from several modern writers commenting upon them very adversely. Mental defect should not be regarded as a unit character, amenable to transmission according to Mendelian laws; he declared that there was no evidence that the neuropathic diathesis was transmitted by Mendelian law, and further, no evidence that mental defectives were unusually prolific. In the third lecture Dr. Clarkson dealt with the general treatment of the individual. The faulty memory which was so difficult an obstacle in teaching was due to lack of interest, and the child forgot at once facts told to him but with which he had no association. Pride and ownership were two primitive instincts useful in training; for example, it was bad to provide uniform institution clothing to each child. Each should have its own clothing in which, therefore, it developed a sense of ownership and pride in keeping the clothing tidy. The instinct towards constructiveness was of great importance, and the child should be taught to do things with his hands. Even destructiveness, which could be turned into useful channels, was better than apathy. The lecturer gave several instances, as, for example, one of a child who had been quite incapable of reading or writing, but who, being put in the joiner's shop, developed interest and became an excellent carpenter, thereafter teaching himself to read labels and other signs necessary for the work in which he was interested. Another example was that

of a girl who had not the mentality necessary to read and who forgot the letters from one day to another, but who became interested in crocheting. She learned to work elaborate patterns, and later taught herself to read the complicated information given in pattern journals. Play, the lecturer said, formed the character of children more than anything else, and the child learned the most important lessons from its fellows. It was impossible for a mentally defective child to play with normal children, who either teased it or ignored it, and were constantly showing up its defects. The question therefore arose whether a child should go to an institution or be brought up at home. This question must be decided in each instance. The advantages of an institution were many; thus a child found in an institution children of its own calibre with whom it could play on equal terms. At home, too, a child often had a bad effect on its mother, both by causing her to neglect the rest of the family, and also by making her nervous from the constant strain required in attention on the defective child. The mentally defective child had, however, little effect on other children, except that, seeing he was usually favoured and not held responsible for his acts, a sense of injustice was raised in normal children. The education authorities at the present time provided special schools in the cities for the instruction of mentally defective children, but the entrance to these should be restricted to children who showed a prospect of being capable of advancement to a fairly normal standard by the age of 16. Children of lower mentality should go to institutions, and there should be far more of these than existed at present. Boarding out, which was so successful in the case of mildly insane persons, was very successful also in the case of mentally defective boys, but was not so suitable for mentally defective girls. The institutions which would be built in the future should be large, because this offered advantages of cheapness in management. It also permitted of classification of mental defectives according to their grade, and gave a chance for providing occupations for the children, which was a matter of great moment in their instruction and development.

SCOTTISH NATIONAL MEMORIAL TO QUEEN ALEXANDRA.

An appeal has just been issued for £150,000 to raise a fund to secure the continued usefulness of the Queen Victoria Jubilee Institute for Nurses in Scotland, and to assist the local district nursing associations, of which there are 400 branches in Scotland. This is to be called the Scottish National Memorial to Queen Alexandra. The appeal points out that the institute was founded by Queen Victoria in 1887, and that the Scottish Council now supplies 700 Queen's nurses, who minister in every part of Scotland to those unable to afford a private nurse, as well as to the necessitous poor, and also provides special courses in district work, infant welfare, midwifery, school, and tuberculosis visiting, and other branches of public health work. The institute provides a home of rest for the nurses free of charge during any period of convalescence, and guarantees to its nurses after training regular employment and a minimum salary and keep, and provides them with small pensions on retirement. The number of nurses trained by the institute has increased from 65 in 1919 to 102 in 1925, and as the cost of board and uniform and other expenses has steadily risen, the council has for some time been faced with a yearly deficit. Many towns and districts are understocked with nurses, and there is a pressing need for extension of services. It is estimated that to cover the whole of Scotland effectively 600 additional nurses are still required.

CONFERENCE ON THE CRIPPLE PROBLEM.

A conference called by the Edinburgh Cripple and Invalid Children's Aid Society will be held in the City Chambers, Edinburgh, on Tuesday next, March 16th, at 3 p.m., at which the Lord Provost will preside. The conference will be asked to appoint a committee to consider every aspect of the question, including the number of existing cripples, the home visiting of cripples, the institution of clinics, the following up of patients after discharge from hospital, and perhaps the provision of beds for the treatment of crippled children and adults.

ANTITUBERCULOSIS MEASURES IN EDINBURGH.

The annual meeting of the Royal Victoria Hospital Tuberculosis Trust was held on March 3rd in Edinburgh. Sir Robert Philip, LL.D., vice-president of the trust, presided, and, in moving the adoption of the annual report, referred to methods of treatment at the Southfield Colony. In the laboratory of this institution they had the fullest opportunities through clinical cases for testing new remedies. Every now and then new remedies were boomed in the press unduly. A large number of authorities had taken the trouble to send them this or that new remedy in order that it might be tested, and their results had tended to corroborate or to lead them to distrust some of these remedies. He wished that that method of testing remedies could be adopted more thoroughly. At the farm of Gracemount a supply of clean milk of the highest character had been secured and a herd of tubercle-free cattle created, thus showing the dairy farmers what could be done on sound commercial lines. He referred to the grant made in aid of tuberculous patients and households as one of the most significant parts of the trust's work. If the mortality figures which prevailed in 1887, when the trust began its work, had prevailed last year, there would have been approximately 13,000 deaths in Scotland from all forms of tuberculosis, whereas the actual figure was 5,389. If the old figures had prevailed in relation to pulmonary tuberculosis, there would have been 9,300 deaths, whereas the mortality was 3,733. While the trust did not claim that all this was due to its activities, it suggested that it was a hopeful line of work in which they were engaged. Colonel P. S. Lelean, professor of public health in the University of Edinburgh, in seconding the adoption of the report, said that at Southfield there was one of the most completely equipped laboratories in Scotland, but the question arose as to who was to endow this necessary work.

The report records several interesting cases of advanced tuberculous disease which had benefited very greatly. It also describes the treatment by sunlight and open air which has been pursued since 1894. The committee has been so convinced of the beneficial effects of this treatment that it has erected a considerable building as a "sun bath," capable of accommodating some fifty patients, which will be completed early in the present year. An artificial sunlight equipment has also been installed. Attention is drawn to the fact that the committee has undertaken the production of tubercle-free milk at Gracemount Farm, Liberton, which has been established to produce clean milk of the highest grade; to raise a herd of tubercle-free cattle; to maintain a dairy farm on sound financial lines; and to serve as a propaganda station in the interests of dairy farmers and of the general public. All these purposes have been successfully accomplished and the demand for the milk has grown continuously. It is calculated that of all milking cows in the country, probably 40 per cent. are infected with tuberculosis, and the difficulty of securing non-tuberculous cows can only be realized by those who have had practical experience. The demand for tubercle-free cows is, however, steadily increasing, and the tubercle-free herd belonging to the Tuberculosis Trust already contains some seventy cows. The trust, in the course of two years, it is expected, will be in a position to sell annually a considerable number of guaranteed tubercle-free animals. Attention is also directed to the laboratory investigations carried out at the Southfield Colony at the request of the Medical Research Council. Much work was carried out with regard to treatment by sanocrysin, and the trust wishes it to be generally known that one of its functions is the investigation of new remedies and lines of treatment.

INFECTIVE JAUNDICE AMONG MINERS.

An important decision was given in a case which came before the sheriff at Dunfermline, relating to the death of a miner from infective jaundice. This is the first case brought under the Workmen's Compensation Act to establish liability of the employer for compensation. The plaintiff was the widow of a colliery foreman who died in 1925 from what was admitted to be spirochaetosis icterohaemorrhagica. Rats caught in the pit had been found on laboratory examination to show the spirochaetes of this disease. The sheriff, in giving judgement, said that the

disease in this case had been contracted by infection from a rat or rats in the pit, and the condition therefore arose out of and in the course of the employment. If the disease had been common in the coal mines of Scotland as it was, for example, in Japan, it might have been regarded as a risk which the coal-miner took as a normal incident of his employment and for which the employer was therefore not liable to pay compensation. As all coal-miners in this country were not exposed to liability to contract this disease, it was held that the death was "an unlooked for mishap or an untoward event, which was not expected or designed," and a sum of £280 was accordingly awarded to the widow of the deceased miner as compensation.

Ireland.

SMALL-POX AND VACCINATION.

The following resolution was adopted by a unanimous vote at a meeting of the Royal College of Physicians of Ireland held on March 5th:

"That the President and Fellows of the Royal College of Physicians of Ireland have had before them the most recent figures as to the prevalence of small-pox in the North of England, and they recognize the risk of the introduction of the disease into Ireland. The President and Fellows deem it to be their duty to urge upon the public health authorities and the public the necessity which exists for vaccination of infants and for revaccination of young adults. These preventive measures, in the opinion of the College, have been proved to promote—if not to secure—immunity against a dangerous infection which in times past was one of the most fatal and dreadful of pestilences."

INCORPORATED ORTHOPAEDIC HOSPITAL.

At the annual meeting of the Orthopaedic Hospital of Ireland the report read by the senior physician, Dr. T. P. Kirkpatrick, stated that this was the hospital's jubilee year. The hospital was founded in the year 1876 at Usher's Island by the efforts of the late Surgeon R. L. Swan and Messrs. B. Journeaux and T. W. Fisher. It began with six beds. In 1883 it was moved to Great Brunswick Street, Dublin, where 48 beds were available. The fame of the hospital spread all over Ireland, and a steady stream of deformed children began to flow in. In 1902 Dr. Swan moved the hospital to its present site in Upper Merrion Street, where 80 beds were available, devoted solely to the treatment of deformities. It was the only hospital in Ireland treating deformities in children exclusively. During the fifty years of the hospital's existence 30,000 crippled children had been treated. Last year 1,576 patients were treated in the hospital—1,375 in the out-patients' department and 201 were given special operative treatment as in-patients. The daily average number of patients was 69. The attendance at the dispensary was the largest on record. Very young children, if brought regularly to the dispensary, could in most cases be cured of club-foot and rickety deformities by manipulative and plaster appliances, thus saving the beds for the more serious cases. There was a gymnasium and national school attached to the hospital. The ordinary expenditure during the year exceeded the receipts by £280, and with a debt of £88 from the year before the governors had now to face 1926 with an overdraft of £368. The Linen Guild, under Mrs. Haughton and Miss Riordan, had a successful year. The governors offered their very special thanks to Sir Neville and Lady Beatrix Wilkinson for the sum of £111, being part of the proceeds of the exhibition of Titania's Palace, held during the summer. This money the governors wished to have allocated to furnishing an outdoor ward. Thanks were also offered to Miss Sweeney, her staff, and pupils of Mount Temple School, who forwarded the sum of £57, the proceeds of a sale of work. That sum was being used, at their request, to buy an Alpine sun lamp. Thanks were also accorded to other friends of the hospital for their services. The Chief Justice, Mr. Hugh Kennedy, said that the hospital had a history of great and growing usefulness. It was astonishing to find that actually 30,000 crippled children had passed through the hands of the skilled staff, and had received attention and treatment which had made many of them

capable of earning their living. The past year, as they would see from the report, was one of record achievement. The financial overdraft with which they were starting the year was an indication that the work had been expanding. The report also gave them a line as to the future growth of the hospital. Experts were all agreed that if the best results were to be achieved a country home was necessary at least as an adjunct of the work being carried on. He appealed to the public to bear in mind the nature of the work and the extent of the relief that had been afforded during the last fifty years, and in particular during the past year.

MOTHER AND CHILD WELFARE.

The report of the mother and child welfare department of the St. John Ambulance Brigade in Ireland shows that with the limited amount of money which the executive committee had at its disposal help was given to many of the poor at a time when not only nourishment was necessary, but when relief from trouble and anxiety was most essential. The daily dinners served to expectant and nursing mothers numbered 7,205; in this branch also 9,452 half-pints of soup were issued. To women attending for these daily dinners seventy-nine babies were born, and all but one of these were alive and healthy. Remembering that many of these mothers were in a state of semi-starvation brought about by the dearth of employment which unfortunately exists in the city of Dublin, it was considered that the Brigade had justified itself in deciding to reorganize the welfare department, and feed the mothers on the premises instead of issuing food tickets as heretofore. Besides the actual feeding, assistance was given in 208 maternity cases; this consisted of double sets of baby clothes, parcels of food, and milk for two weeks, and in some cases when the mothers were unable to nurse their babies patent foods were issued, and continued for nine months. Through this department 204 sick children were helped by the issue of milk, food parcels, and warm clothing. At a recent meeting Sir John Lumsden, F.R.C.P.I. (chairman), urged the committee to use its best endeavours to bring the work of the welfare department before the charitable public of Dublin; its resources were so slender that it was only able to help a very small proportion of the victims of the economic conditions prevailing in the city to-day.

England and Wales.

MR. ALBERT LUCAS OF BIRMINGHAM.

MR. ALBERT LUCAS, who until recently was senior surgeon to the Birmingham General Hospital, has retired under the age rule. On March 5th he was presented with an illuminated address and his portrait at a meeting of the governors, medical and surgical staffs, and the officials of the hospital, at which Sir Gilbert Barling, president of the hospital, took the chair. On the same occasion Mrs. Lucas, who is chairman of the Samaritan Committee, was presented with a piece of jewellery. Mr. W. S. Houghton, chairman of the House Committee, read the address, which was in the following terms:

As representatives of the Board of Management and of the medical staff of the General Hospital, we tender to you our profoundest thanks for thirty-five years' invaluable service to this institution, in the development of which you yourself have played the part of a leader. Your skill as a surgeon, your ability as a teacher, your counsel in committee, together with the happy relations which have always existed between you and your colleagues, and your wide experience of voluntary hospitals generally, and in the affairs of your own profession, have all been of considerable advantage to the hospital.

We should not do justice to your career if we failed to place on record the respect and affection which is felt for you by those who have been associated with you in the great work which gives us a common and binding interest. We wish to add our appreciation of the quiet but effective work of Mrs. Lucas as member and chairman of the Samaritan Committee. We are glad that

as consulting officer you will maintain for a time active association with the hospital, and we hope that both you and Mrs. Lucas will long be spared in health and happiness to enjoy the retirement which your long and valuable services to the city entitle you.

Mr. Houghton said that Mr. Lucas had come to the hospital as resident surgical officer in 1892, and gratitude mingled with love and admiration was due to him for all he had done; he was glad to think that the hospital was not to lose the services of Mr. and Mrs. Lucas altogether. Sir Gilbert Barling handed the address to Mr. Lucas, and expressed the hope that he would have many years yet of activity and health. Mr. L. P. Gamgee, senior surgeon, said that Mr. Lucas had always put the interests of the General Hospital at the forefront of his endeavours and had worked single-minded for its good. He had himself become connected with the hospital soon after Mr. Lucas. A more kindly and loyal colleague it would be impossible to have, for Mr. Lucas was always ready to sacrifice his own interests in assisting his colleagues.

Mr. Lucas, in returning thanks, said that he had received during the whole period of his service many kindnesses. The surgical work of the hospital had greatly increased; in his first year there were 600 operations and in the last year 8,000. He had faith in the voluntary hospital system, and he knew that Mr. Neville Chamberlain, who had at one time been chairman of the hospital, and in that way gained much knowledge useful to him in his present position as Minister of Health, would gladly make a large grant for the enlargement of hospitals if the financial position of the country permitted. The General Hospital, however, required a certain amount of enlargement, and if its needs were better known he felt sure they would be supplied. The General Hospital had always been the first thing in his thoughts; he had put the best years of his life into the service of the institution, and his work had afforded him the greatest gratification.

Mrs. Rickards then presented Mrs. Lucas with a piece of jewellery on behalf of the subscribers, who were very glad to know that the hospital was not to lose her services as chairman of the Samaritan Committee. Mrs. Lucas suitably acknowledged the gift.

"DISTRICT NURSING IN LONDON.

At the annual meeting, on February 25th, of the Central Council for District Nursing in London the executive committee reported that there had been a satisfactory increase of work during the year. New associations had been established in Norwood, Willesden, Heston, and Twickenham, and certain existing associations had extended their borders. The committee decided to distribute £1,350 during 1925, allocating part of this sum for specially necessitous areas. The trustees of the London Parochial Charities had entrusted the council with £2,600 for distribution, and provided £300 for administrative expenses. They also gave £100 for midwifery training bursaries, to be awarded to nurses in federated associations who were prepared to undertake midwifery or maternity nursing in London. Three nurses had entered for training during the year, making a total of nineteen trained in this way since the grants were first made. The Association for Promoting the Training and Supply of Midwives had again been willing to make arrangements for the booking of vacancies at suitable institutions; these bursaries had been found to be of great value. The new housing estates established by the London County Council present fresh problems as regards district nursing, since, although in some cases they are situated outside the county area, their population is almost wholly drawn from the metropolis. The executive committee, therefore, felt it necessary to secure nursing provision for the Becontree estate, and it conferred with the Essex County Nursing Association, who agreed to establish a branch home at Dagenham, and to provide district-nurse midwives for the inhabitants. The difficulties of the Tottenham area have been overcome temporarily by two neighbouring associations extending their sphere to cover the greater part of the district; it is hoped that eventually a local association will be established. The Southgate association, which, received a grant to

enable it to extend its work to a particularly poor area, has now repaid this grant, which becomes available for a needy district elsewhere. A census of district nurses in relation to population has been prepared by Sir Arthur Newsholme, from which it appears that the average for the entire metropolis is one district nurse to 18,120 persons; thirteen boroughs are above this average and fourteen below it. It is recognized that more nurses are required in London, but at present the associations are unable to extend owing to lack of funds. Grants and donations have been received from the trustees of the Peabody Donation Fund, the trustees of the Guinness Trust, the Ministry of Health in respect of midwifery and maternity nursing, from the Fishmongers' and Ironmongers' Companies, and certain private individuals. The representatives of the British Medical Association on the central council are Mr. E. B. Turner, Dr. T. W. H. Garstang, and Dr. William Paterson.

DR. JAMIESON HURRY AND READING.

Dr. Jamieson B. Hurry, on the occasion of his leaving Reading, has presented the royal borough with another historical picture dealing with Reading Abbey. The picture was painted by Mr. Stephen Reid; it was exhibited in the Royal Academy in 1924, and subsequently for a time in the House of Commons. It depicts the Parliament of King Henry VI at Reading Abbey in 1453. The King is seated on his throne, the bishops and mitred abbots are seated in rows on his right hand, and the lords temporal on the left. In the centre of the picture is an inner square of four woolsocks for the chancellor and various judges; behind them are the clerks of Parliament and the Crown. Dr. Hurry has now presented ten pictures in all to the borough, each of which has been painted by an artist after careful historical research. The series thus comprises a valuable guide to the history of Reading Abbey, and includes such incidents as the burial of Henry I, the founder of the Abbey; the consecration of the abbey church; the execution of the last abbot of Reading in 1539; and the enthronement of Elizabeth, Queen of Edward IV—Dr. Hurry's previous gift, which we mentioned on July 19th, 1924 (p. 135). Dr. Hurry has been a resident in Reading for forty years, and has made numerous gifts to the town, including books dealing with the history of the Abbey, and benefactions in connexion with the Forbury Gardens, the swimming baths, and the gymnasium. He was formerly surgeon to Reading dispensary and medical officer of University College.

CENTRAL MIDWIVES BOARD.

The Central Midwives Board for England and Wales met on March 4th for a penal session, followed by the ordinary meeting. Dr. R. A. Lyster was appointed to represent the Board at the congress of the Royal Institute of Public Health. Approval was given to the scheme of training submitted by the Tynemouth Guardians. It was agreed that the approved lecturer at Lambeth Hospital should be invited to co-operate with Dr. E. W. G. Masterman, medical superintendent of St. Giles's Hospital, Camberwell, in the delivery of lectures to pupil midwives. The suggested amendments of the Midwives Act, 1902, and the alterations in the rules of the Board were considered, and it was resolved that the Minister of Health should be asked to provide for the amendment of Section 1, Sub-section 2, of the Midwives Act, 1902, by the addition of the following clauses:

1. Any unqualified person rendering assistance to a woman in childbirth in a case of emergency shall, without delay, summon a qualified medical practitioner or a midwife to the case.
2. Any person failing to comply with the foregoing clause shall be liable on summary conviction to a fine not exceeding £5.

The Board approved the form for recording ante-natal notes, and decided that this should be printed by the Board's printers both in card and book form and be placed on sale. The following re-elections to the Board were announced: Dr. J. S. Fairbairn, Miss M. E. Pearson and Miss A. A. L. Pollard by the Midwives Institute, and Dr. J. J. Jervis by the Association of Municipal Corporations.

Correspondence.

HOSPITALS FOR THE MIDDLE CLASSES.

SIR,—I read with much interest your leader in the *BRITISH MEDICAL JOURNAL* of February 27th (p. 385). It summarizes very ably the need of the middle classes for skilled medical service at reasonable cost, and the difficulties that a satisfactory solution of the problem presents, that were the outstanding features of the recent correspondence in the *Times*, in the *Spectator* last summer, and in a recent long letter to the *Western Daily Press* by Professor Morton of Bristol.

A fundamental error in the minds of nearly everyone taking part in the discussion is the belief that the solution of the problem lies in the provision of inexpensive nursing home accommodation. The nearly twelve years' experience of St. Chad's Hospital proves that an institution equipped to fulfil the requirements of modern medicine in the investigation and treatment of disease cannot be "cheap" either in respect of initial or maintenance cost. Nor, if it were possible, would it solve the real difficulty—namely, a reduction of at least 50 per cent. in the total cost of treatment in ordinary nursing homes at ordinary fees.

A cheap nursing home or private hospital involves inadequate equipment, poor nursing, and conditions that would not be tolerated, as you rightly point out, either by the patients or the medical staff. Money sufficient to provide and maintain an institution on proper and efficient lines must be provided from some source.

In Birmingham the total cost of an ordinary major operation involving three weeks' stay in a nursing home is about seventy-five guineas. The cost of a similar operation in a voluntary hospital is about twelve guineas, provided partly either directly or indirectly by the patient, or from charitable funds. The problem is to provide as satisfactorily for the large numbers of people to whom the ordinary cost is prohibitive or excessive, and who are yet in a position to pay a moderate inclusive fee—for example, £40 to £50. Nursing home charges average eight to ten guineas a week, and no possible reduction in these would materially help to reduce total cost.

The experience of St. Chad's proves that the cost of the nursing institution cannot be reduced beyond seven guineas a week without sacrifice of efficiency. This provides for a resident medical officer and all the departments and equipment of a voluntary hospital. If relieved of capital charges, rates, taxes, etc., that a voluntary hospital has not to meet, the cost might be covered by five guineas a week, which must be regarded as the minimum cost of maintenance for paying patients even in a voluntary hospital. When the ordinary maintenance cost is about £4 a week it is ridiculous to think that a better class of patient can be received and satisfied for three or four guineas a week unless they are to involve a drain upon, instead of adding to, the general income of the hospital. If it is accepted that cheap nursing institutions are undesirable and would not solve the real difficulty, a great advance will have been made. A charge of one guinea a day allows of the provision of a modern hospital replete with the equipment necessary for satisfactory investigation and treatment of disease in an environment that provides the amenities expected by paying patients. It allows of a moderate return on capital invested and provision for gradual repayment of such capital. In other words, such an institution is economically sound and requires no help from charity nor subsidy from the State or rating authorities. If this ideal is sacrificed and an attempt made to provide for patients at an uneconomic rate, endless difficulties are encountered. The difference in cost to a patient on a three weeks' stay between the full economic charge and the bare cost of maintenance in a hospital ward is only about nine guineas, and does little to reduce the total fee.

I am convinced that the problem can only be solved satisfactorily by allowing an adequate sum for the upkeep of the nursing institution, whether this be an annexe of a voluntary hospital or a separate hospital for paying patients only. The real benefit in the way of reduction in

total cost can only be given by a modification in the professional fees agreed to by the medical staff with the assistance of an almoner.

The question of insurance that you raise in your article is an all-important one. Insurance would make it possible for a far larger number of patients to obtain the advantages of treatment in a pay hospital than is the case when necessity arises without provision having been made to meet the cost. If machinery for the treatment of insured persons were available at a fixed rate, the problem of insurance would be a very simple one and protection against illness requiring expensive treatment secured at low cost.—I am, etc.,

Edgbaston, March 4th.

WILLIAM BILLINGTON.

SIR,—Respecting your leading article, "Hospitals for the middle classes," in the *JOURNAL* of February 27th (p. 385), many West End specialists have told me of their dissatisfaction with existing homes, and the need for a home with facilities for diagnosis and treatment.

In consultation with a number of these specialists, a scheme has been worked out in detail for a high-class home having the following features:

1. A good, open position, away from traffic and dust; good bedrooms with a good outlook, and garden, lounge, and sitting-rooms for such patients as are able to use them.
2. Within fifteen minutes of the West End.
3. An up-to-date theatre, x-ray and electrical plant, and a pathological laboratory.
4. A resident medical superintendent to control the home and be available in emergency. The home would, of course, be open to any medical man to attend his patients.
5. Fees not above, and in many cases below, those of existing homes.

A house is available in an excellent position, having nothing of the "institution" style, and with unique features and amenities. There is ample room for extension beyond its present capacity, which is about twenty-five patients.

The necessary capital is still to be found, amounting to about £25,000. As a commercial proposition it would be very remunerative; if, on the other hand, some philanthropist would be satisfied with, say, 6 per cent., a reduction of fees would be possible, and a very great step forward made in the interests both of science and of the public.

I shall be glad to give full details to anyone interested.—I am, etc.,

E. C. PLUMMER, M.R.C.S., L.R.C.P.

Ealing, March 2nd.

THE DEVELOPMENT OF VAGINAL OPERATIONS FOR GENITAL PROLAPSE.

SIR,—I am very glad that the second volume of my book, *The Statics of the Female Pelvic Viscera* (Lewis, 1925), which Dr. Fothergill recently reviewed,¹ has stimulated him to give the lecture published in your issue of February 13th. I could not have been paid a greater compliment: and I thank Dr. Fothergill, sincerely and gratefully, for referring to my work. But we are as much opposed as in 1907. Dr. Fothergill believes the pelvic viscera are retained in the pelvis by their connective tissue attachments; I believe they are retained because the pelvic floor—a musculature—prevents them from being pushed out.

If in reading Dr. Fothergill's lecture I have a regret, it is that the distinguished author did not refer to my conception of "genital prolapse"—that it is an extrusion, a true hernia, comparable with any other hernia. I called the condition "pudendal hernia"; and I gave reasons for such change in name. I still have hopes that the profession in general, and Dr. Fothergill in particular, may come in time to recognize that genital prolapse is a hernia, and that it must be treated like a hernia. The matter is of importance—not simply from the point of view of curing the patient, but because it raises the conception of the intra-abdominal pressure into prominence, and thus sheds a light on the whole of internal medicine. All the world

knows that the "negative" intrathoracic pressure is essential to life—that it profoundly affects "general metabolism": not all the world knows that the "positive" intra-abdominal pressure is as important from the same point of view. The moment we see this—that the intra-abdominal (positive) pressure is as important—what changes in juxtaposition of ideas of abdominal visceral disease must we make? It is not only that the so-called "toxaemic" states in pregnant women become illuminated, it is that even in the non-pregnant light is shed on visceral aberration. My conception is based on a study of the whole of vertebrate evolution. In 1910 I showed that the pelvic floor muscles are not essentially tail-movers, but exist for the purpose of maintaining an internal pressure within the abdomino-pelvic cavity, adequate for the needs—that is for the general metabolism—of the individual.² It is supported by clinical studies in man—by the occurrence of neurasthenic states with diminished pressure, and the rise of eclamptic phenomena when the pressure is unduly raised.

While my conception leads to further issues with which professors of medicine in time will have to deal, Dr. Fothergill's conception, as far as I can see, leads nowhere. Nor is his conception whole-heartedly supported by surgery. No one, as far as I know, has cured a case of marked genital prolapse—that is, of extrusion—by operating on the visceral connective tissues alone. Even Dr. Fothergill himself performs a perineorrhaphy or colpo-perineorrhaphy—an operation in which he probably, and most other surgeons certainly, performs a myorrhaphy of the levators. Why does Fothergill do this if his conception is sound? Again, in his lecture, as in his operative work, Fothergill advocates resection of a "wide portion of the vaginal wall," so that the connective tissues lateral to the genital organs, can be reached and dealt with. But Chipman, at the Congress of Obstetrics and Gynaecology held in London in April, 1925, read a paper in which it was stated that wide resection was unnecessary. I was present, but to my regret Dr. Fothergill was not. Professor Chipman (I understand) also conforms to Dr. Fothergill's hypothesis; but he also (I believe) performs a perineorrhaphy in which a myorrhaphy of the levators is done. But how, if in genital prolapse but a narrow strip of the vagina is removed, can the parametria or the paracolpitic tissue be dealt with?

The proof of the pudding is in the eating; and I was bound to try the effect of my own ideas in prolapse. I have had few cases, but in such as have come my way I have put my ideas to the test, staking all on the result. In 1919 I exposed the levator ani in the dead; and in the same year began treating patients suffering from genital prolapse by dealing with this muscle, which is so often severed from its normal attachment anteriorly, on one side or on both, by childbirth, and found displaced laterally. My idea was to alter the position of the muscle to give it a more median position. My earlier operations all failed because I did not know how to make the muscle stick to the bone, but subsequently I have had successes. I cite three cases.

A young woman, after childbirth, in which forceps were used, found herself "all to pieces." A ring had to be inserted; it did not altogether relieve, and larger rings were used, which, however, could not be retained. I was asked to see the patient, and operated. I exposed the left levator ani, and altered its position, giving it a more median attachment. The attachment held, and the patient has since been able to do everything she wanted, to walk miles, without the use of any pessary.

A patient of my own had a precipitate labour. Subsequently she found herself "all to pieces." I operated; the operation failed. Even before leaving her bed, on vaginal examination one found that the more median attachment of the muscle had disappeared. She had a bath-chair convalescence. I advised a further attempt. In six months, in spite of invitation to go to some other centre at which orthodox gynaecological precepts would have been followed, she consented to try at my hands her luck again. This time the operation succeeded, and the patient has been so pleased with the result that she has more than once stated she would willingly submit to examination by any who may be dubious.

A patient with marked cystocele was sent to me; I operated first on the left side, and later on the right; the patient has been cured of her trouble, and when I last saw her told me she could not only do her own washing, but took in the washing of neighbours to augment her income.

² Hunterian Lectures: "The Evolution of the Pelvic Floor in the Non-mammalian Vertebrates and Pronograde Mammals," *Lancet*, May 21st and 28th, 1910.

¹ *Journ. of Obstet. and Gynaecol. British Empire*, vol. 32, No. 4, 1925, p. 744.

In none of these cases were the connective tissue attachments of the genital organs touched. Even in the interposition operation, an operation of value in many post-climacteric cases, and which cures the symptoms, the connective tissue attachments are not touched. Dr. Fothergill ought to consider the effect of the last operation on his conception of prolapse, but he does not do so. In my own operation cases, thirty-five to date, I have had sufficient successes to confirm my view.—I am, etc.,

Rugby, Feb. 13th.

R. H. PARAMORE.

CARBON DIOXIDE IN ANAESTHESIA.

SIR,—In your editorial on the carbon dioxide control of anaesthesia (BRITISH MEDICAL JOURNAL, February 27th, p. 387) there appears to be a slight misconception. The contradiction between Professor Yandell Henderson's figure of 25 per cent. of carbon dioxide and Dr. Lundy's figure of 5 per cent. is only an apparent one. Professor Henderson recommends the use of cylinders containing 25 per cent. of carbon dioxide and 75 per cent. of oxygen. In practice this is diluted with air or other gases, and when given at such a rate as to produce the optimum amplitude of respiratory movement the resultant mixture, as actually inspired by the patient, would contain approximately 5 per cent. of carbon dioxide.

During the past few months a number of Edinburgh anaesthetists have been using cylinders of pure carbon dioxide, the gas passing through a flow-meter and being delivered under an ordinary Schimmelbusch mask. It has been found that when carbon dioxide is used in this manner for adults of average size, at a rate of 2 litres a minute, the respiratory minute volume is approximately trebled and the induction or deepening of anaesthesia with ether alone is greatly facilitated.

In order to produce the desired increase of pulmonary ventilation with a mixture containing only 5 per cent. of carbon dioxide it would be necessary to exclude air almost completely. As in these circumstances the respiratory minute volume would, in ordinary adults, be approximately 15 to 20 litres a minute, this would necessitate, except in apparatus where the gas is conserved during the expiratory phase, a rate of flow of from 30 to 40 litres a minute. This would be extremely wasteful, and at this rate a large 100 cubic foot cylinder would last only about an hour and a quarter. Moreover, the oxygen percentage would be unnecessarily high. Therefore, from the point of view of economy as well as of portability and convenience, the higher percentages are to be recommended.

One can readily confirm the reports of the advantages of the use of carbon dioxide. It is a most valuable and powerful respiratory stimulant. Although in the use of gases, as in other therapeutic procedures, exact quantitative methods of administration are highly desirable, yet in the case of carbon dioxide ease and delicacy of control are the chief essentials. The immediate and easily observed respiratory response renders it possible to use carbon dioxide with the simplest appliances, the optimum amount being the minimum which will produce the required clinical result rather than any arbitrary percentage or rate of flow.—I am, etc.,

H. WHITRIDGE DAVIES.

of Edinburgh, March 2nd.

MENTAL IRRITABILITY AND BREAKDOWN IN THE TROPICS.

SIR,—I hope you will allow one who is not a member of the medical profession to ask those readers of your paper who have special knowledge to give their opinion on a subject of health which is of enormous importance to Europeans who live in the tropics. The subject is: What is the cause of the upset of mental balance which is so common in the tropics? This upset ranges from excessive irritability or loss of judgement to lunacy or suicide.

The frequency of deterioration and breakdown is all the more remarkable because countries such as British Malaya are now distinctly healthy, but "nerves" are as frequent a cause of breakdown as ever. Take the position in British Malaya, where my work has been for sixteen years. The

total number of Europeans in Government service in the superior grades is now less than 1,100. Ten years ago it was much less. For the last eleven years (the period during which I have taken special notice) there have been about two cases a year regularly among Government servants of insanity or suicide, and many others among the other white persons here. During the last six months two have been invalided out of the service for "nerves," and two others who were in positions of great honour and responsibility have shot themselves. It is sometimes supposed that irregular living is a disposing cause in such cases. Nothing could be farther from the truth than this. I have known for years each of the four persons just mentioned. I believe that each one was a scholar of his college at Oxford or Cambridge; at least three out of four had won distinction in sport; each, I believe, was beyond reproach as regards regularity of life.

Nor is it only in extreme cases of breakdown that this tendency shows itself. Everyone who is in charge of any large body of Europeans knows how carefully he has to consider any signs of those under him becoming "nervy." I find also that the difficulty is not confined to our part of the world. Dr. Norman Leys, in his book on Kenya Colony, describes exactly the same difficulty. After giving two very revolting instances of the effect of loss of self-control by Europeans in that colony, he goes on: "Few of us who have lived in Africa have no reason to be ashamed of what we have done to Africans on such occasions" (p. 165). Later (p. 167) he talks of the "excessive irritation in Europeans" caused by faults in Africans. Conversation with those who have lived in that colony or visited it on business had given me the same impression before I read Dr. Leys's book.

The tropical colonies and dependencies of the empire are of great importance to us, both in producing wealth and in providing honourable careers for our young men. I think, therefore, that it would be a benefit if doctors and others who have experience of different tropical countries would give their opinion founded on observation as to the cause of this strain on the nervous system. We should then be in a position to take such steps as would minimize the harm in the future. Dr. Leys says that "the tropical sun can scarcely be blamed, as the peculiar type of crime under discussion is unknown in many tropical countries. Altitude is perhaps a likelier factor. Living in the Kenya highlands at first produces a feeling that encourages one to expect from oneself and from others more in the way of both mental and physical exertion than is ever done." Personally, I do not believe that altitude in itself has much to do with the matter. As far as I know, dwellers in Ootacamund or the other South Indian hill stations, or in Newara Eliya in Ceylon, or in the Java hills, do not suffer in this way, though all these places are within the tropics. In Simla the difficulty did not arise at all. In British Malaya we look to a visit to the hills to abolish the feeling; and the effect, as Dr. Leys describes it, of beginning life in the Kenya highlands is exactly the same as comes during one's first few months at sea-level in British Malaya. Comparatively few in Malaya ever go to any height above sea-level. None live permanently more than 200 feet up.

In Malaya it is usual to ascribe this effect of "nerves" to the sameness of the climate all the year round, and to the perpetual moist heat. But whereas in Singapore the temperature (in the shade) only varies from a maximum of 94° to a minimum of 70°, in Kenya the temperature varies considerably and for many months there is dry weather. So that explanation will not account for a similar effect in the two countries.

A different explanation was given me by a man of ability who had studied conditions in Kenya. It was, he said, the bright light of the long period of rainless days which is a feature of the Kenya highlands. To me that seems possible, particularly as, in spite of frequent showers, we live mostly in bright light in Malaya the whole year round, and this seems to have been felt very much by some Europeans who had to be sent to the asylum, whereas most of us find cloudy days soothing. But although many considerations make me inclined to accept this explanation, I do not feel that I have enough data to put forward any theory with

confidence. It is, therefore, with the hope that others from different parts of the tropics will state the effects of their observation that I write this letter. If excessive light is the cause, would its ill effects be prevented merely by the use of dark glasses, which are common in the plains of India, but not in Malaya? Or should other precautions be taken too?

I must apologize for the length of this letter. But the subject is of such importance to those whose work lies in the tropics that I hope that you will admit it to your columns in spite of this defect.—I am, etc.,

C. J. SINGAPORE.

Bishopscourne, Singapore, December, 1925.

UNIVERSITY REFORM IN LONDON.

SIR,—In his review upon Mr. Humberstone's book on London University your reviewer makes certain misstatements of fact which I beg your leave to correct, more especially as the whole review bears the aspect of an attempt at propaganda, which I am especially concerned to controvert. I have not read Mr. Humberstone's book, and do not know whether your reviewer has obtained his information from that volume or from his own inner consciousness. I submit that it is inexcusable to repeat Mr. Fisher's statement of January, 1925 (which he quotes), because I publicly corrected that statement in a letter published in the *Times*, and my correction was not disputed by Mr. Fisher.

Your reviewer, following Mr. Fisher, says the site of "eleven and a half acres" near the British Museum was a "present" to the University. The site available for building offered by the Treasury is eight and one-third acres, not eleven and a half, and it was in no sense a "present" but, in fact, an exchange, extremely disadvantageous to the University, which was asked to give up the site and buildings at present occupied respectively by King's College and by the headquarters of the University, in exchange for the bare site at Bloomsbury. How grasping the "bargain" proposed by the Treasury really was may be gauged from the significant fact that, some four years later, the Treasury was shamed into adding to its original offer the payment of £370,000 as an equivalent for the buildings of King's College, for which it had in the original offer suggested no compensation whatever. Inasmuch as the buildings of King's College had been independently valued by the surveyor to the London County Council at the sum of £800,000, it is not surprising that even this additional offer was politely declined by King's College. Your reviewer disputes my assertion that "if King's College declines to shift the whole Bloomsbury scheme must fail." This statement was made by me before the decision of the Senate of June last year; the complete accuracy of my assertion is demonstrated by the action it took, when this resolution was passed *nomine contradicente*: "As it is certain that the expense of rebuilding King's College on the Bloomsbury site . . . would far exceed the sum of £370,000, and, as the Lords Commissioners of His Majesty's Treasury are not able to hold out any hope that Parliament could be asked to contribute a larger sum than £370,000 . . . the Senate find themselves compelled to decline the offer (contained in Mr. Fisher's letter of April 7th, 1920) conditionally accepted by the Senate on October 20th, 1920."

Your reviewer seems to view with complacency the composition of the departmental committee appointed by the Labour Government under Lord Haldane's inspiration in 1924. Your reviewer's complacency is not shared by Convocation. At one of the largest meetings of that body ever held (October 14th, 1924) it was resolved, *nomine contradicente*, "that this House protests against the appointment of a departmental committee on matters connected with London University, and, further, against the omission of any representative of Convocation from its personnel." As a result of this resolution I was invited, as member of Parliament for the University, to approach the present President of the Board of Education with a view to adding to the committee at least one person who might be regarded as being not avowedly hostile to the existing constitution of the University. In response to this request from my

constituents I did, in fact, interview the President upon this question some short time after his assumption of office. The President refused to make any additional appointment to the departmental committee upon the ground that he was in no way responsible for the formation of that committee, and wished to avoid all personal responsibility, which might attach to him if he now made any appointment.

Your reviewer analyses the personnel of that committee, which, from his point of view, is doubtless entirely satisfactory. I submit that, inasmuch as one of the terms of reference of that committee was "to indicate what are the principal changes now most needed in the existing constitution of the University of London," it is unfortunate that so many members of that committee had publicly expressed extreme discontent with the existing constitution and are notoriously prejudiced against its maintenance. In this respect they are in direct conflict with the great majority of members of the Senate, and of members of the University as well. In support of these statements I adduce the following evidence:

The Senate, at its special meeting of October 9th, 1924, passed a resolution declaring its opinion "that such changes in the organization of the University as are necessary may be more readily effected by amendments promoted by the University than by a statutory revision of the University as constituted by the Act of 1898."

This view was upheld by the joint report submitted in identical terms by the delegates from the Academic Council and the Council for External Students to the departmental committee in March, 1925. These two councils command a permanent majority of the Senate. That the large majority of the members of the University are similarly opposed to the reconstruction of the University by an outside dictation is, I think, sufficiently proved (1) by the resolution of Convocation quoted above; (2) by my own election to Parliament, for the University issue was the predominant issue in that election. All my competitors found themselves ultimately obliged (sometimes belatedly) to endorse my own views against that reconstruction; I was elected because I was regarded as the most consistent exponent of those views.

May I, in conclusion, point out that renewed discussion of the Bloomsbury site is at the present moment rendered somewhat fatuous, in view of the probability that upon the first of next month the option upon the Bloomsbury site, secured for a period by the Government in 1920, automatically lapses? This assertion may be disputed, but it has the authority of the Chancellor of the Exchequer, who plainly told us in March, 1924, that unless King's College and the University administration could agree within the time limit (April 1st, 1926) to remove to Bloomsbury the question would be decided by the cessation of the option and the return of the site to the Duke of Bedford.—I am, etc.,

London, W.1, March 5th.

E. GRAHAM LITTLE.

* * The reviewer thought that in Mr. Humberstone's book *University Reform in London* there had at length been found an impartial statement of the long and confused history of the University of London, and is inclined to adhere to that opinion. Dr. Graham Little might do well to read the book before so vehemently controverting some of the statements it contains. The point about the area of the site is dependent on whether or not roadways are provided. Dr. Graham Little, in his letter published in the *Times* of January 17th, 1925, deducting the roads, made the site to be "a fraction over eight acres." Mr. Fisher, in the next issue of the *Times*, adhered to his statement that the site measured "eleven acres and over." In another letter to the *Times* (January 28th, 1925) Dr. Graham Little quoted, from a report of the official valuer of the London County Council made in July, 1920, the statement that the figure eleven and a half acres could only have been arrived at by including the area of the public streets Torrington Square and Keppel Street, together with the open place at the rear of the British Museum, and also the gardens of Torrington Square. He estimated the building site at about eight and a half acres, the area of Torrington Square adding about one acre.

The second point made by Dr. Graham Little, in January, 1925, was that in the event of the removal of the University from the Imperial Institute, Kensington, and of King's College from the Strand, to Bloomsbury, the Government would enter into possession of these two buildings. This, so far as it went, seemed a reasonable proposal. Undoubtedly a greater difficulty exists in the third point raised by Dr. Graham Little in his letter of January 17th, 1925—namely, that neither the University nor King's College has funds to meet the erection of the new buildings which would be necessary. Mr. Fisher, in his reply to Dr. Graham Little, pointed out that the University had not yet appealed to the public for the sum required to develop the Bloomsbury site, and expressed the view that "when it does it will not find the task so difficult as Dr. Little desires to make it." So far as we are aware or can ascertain, the University at present occupies its offices at the Imperial Institute on sufferance. Surely everyone will agree that it ought to have its own site and buildings. The Senate is reported to have accepted the original offer subject to the condition that the move was not to take place until accommodation was provided equal to at least 50 per cent. more than was at present occupied, and that maintenance charges were met by the Government. From correspondence between the Treasury and the University, published in our issue of July 4th, 1925, it appears that the Treasury has accepted the refusal of King's College to move as final, but has asked the University whether it can suggest any practicable alternative for an increase, without undue cost, in the accommodation of the University's central offices. The Treasury added, however, that it might be possible to make arrangements with the vendors of the Bloomsbury site whereby at least a part of it might be occupied for other university purposes. It appears that last October the Senate asked whether any portion of the site would be granted as a gift, or, alternatively as is understood, for increased accommodation at the Imperial Institute. The matter must be put thus conditionally, because it is not referred to in the excerpts published in the *London University Gazette* from the minutes of the meeting of the Senate held on October 21st. For this proposed extension at South Kensington the Senate has, it is stated, obtained architects' plans.

THE ACTION OF CERTAIN ALLEGED INTESTINAL ANTISEPTICS.

SIR,—In the *JOURNAL* of February 27th (p. 367) you publish an article by Dr. Lawrence P. Garrod on the action of certain alleged intestinal antiseptics. As the conclusions arrived at, in so far as our own product dimol is concerned, are in direct opposition to the clinical evidence, we would ask you to give publicity to the following facts, not only in justice to ourselves, but also in the interests of thousands of medical men prescribing dimol successfully.

It is evident that the author of this paper is not familiar with the literature. We hold no brief for three of the products mentioned, but when he says "their composition is unstated" he is misleading his readers; the composition of dimol has been published for over five years. As regards the efficiency of dimol, we are prepared at all times to demonstrate the accuracy of our claim to a Rideal-Walker coefficient of 35.0: from this it follows that by the ingestion of four pulverettes or tablets the patient receives the bactericidal equivalent of 140 grains of pure phenol, which is not absorbed; after doing its work it is voided with the faeces, from which it can be recovered.

It is well known to all investigators that the methods available at the present time of enumerating the colonies of living bacteria in the faeces (including the one described by Dr. Garrod) are probably not accurate to within 100 per cent. In Table I, according to Dr. Garrod's own figures, the count increased from 40 millions per gram before administration to 100 millions during administration—that is, 150 per cent. The futility of attempting to draw any conclusions under such conditions must surely be obvious to all unbiased minds. The mass of clinical evidence which has been accumulating during the past five years in support of the claims made for dimol is perhaps the best reply to

Dr. Garrod. This shows that the dosage above referred to may be repeated four or five times a day without affecting the appetite or digestion, and without any action on the mucosa; and, moreover, that the dosage is so regulated that the *B. coli* normally present are not affected, whereas it destroys the causal agents of infection and putrefaction.

Any investigation based solely on the *B. coli* count is, therefore, to be ignored in connexion with the normal dosage of the dimol pulverette or tablet. If Dr. Garrod is really interested and would like to learn how the entire flora in the fluid portion of the intestinal tract can be destroyed by dimol when taken in the form of a lavage, without injury to the mucosa, we should be very pleased to furnish him with full particulars.

According to Dr. Garrod, dimol destroys all *B. coli* in the dilution of 1 in 200, but only a proportion of the hardy saprophytic streptococci of the normal faeces at 1 in 200. We are at a loss to understand how this result was arrived at, and can only assume that the solution of dimol used was improperly made, as would appear to be the case, as he states that he did not obtain complete solution.

In conclusion, we should like to refer Dr. Garrod to the following extract from one of the many reports received from distinguished bacteriologists who have employed dimol:

"I have been using dimol a lot in the treatment of the secondary infections. Here in Bengal when any infection occurs in the intestine, the flora is often completely altered. Instead of getting the colonies of lactose fermenters, the plate is often crowded with minute colonies of streptococci, yeasts, and late lactose fermenters. The administration of dimol in a few days' time alters this plate picture and the colonies then are more like the coliform organisms.

"Calcutta, May 30th, 1923."

London, E.C., March 4th.

DIMOL LABORATORIES LIMITED.

We have referred this letter to Dr. Lawrence Garrod, who writes:

SIR,—I find in the letter from Dimol Laboratories Limited no criticism of my article the proper reply to which cannot be found in the article itself, except their reference to the composition of dimol. I was aware that the formula of their product had been published, and to have included it in the observation that "the composition of these drugs is unstated" is an oversight which I regret. At the same time, I would again direct its manufacturers' attention to the fact that a "pulverette" described as containing 1 grain weighs, after removal of its sugar coating, about 4 grains, so that another substance is presumably mixed with the active bactericide. This affects the question of solubility to which their letter refers: I can only say that the entire contents of a dimol pulverette do not dissolve in water at 1 in 200, and if the bactericide proper was not completely dissolved in my solution it was not because that solution was "improperly made," but because the drug is not soluble in that dilution. I invite the Dimol Laboratories to state the solubility of dimol in water.

With their references to clinical evidence, and the effect of intestinal lavage, I have no concern, since these subjects are definitely outside the scope of my article. Nor does it appear necessary to dispute their criticisms of the method employed (although I do not admit that it is inaccurate), because they themselves admit that "the *B. coli* normally present are not affected." The remainder of this sentence in their letter expresses the claim which, I again submit, demands authoritative and detailed substantiation. This will not be forthcoming if the Dimol Laboratories rely solely on information of the vague and unconvincing character to be found in the letter which they quote. What organisms are meant by "the causal agents of infection and putrefaction," and what evidence is there that dimol administered by the mouth will destroy them? That *B. coli*—which, as my experiments showed, is many times more susceptible to the action of dimol *in vitro* even than streptococci—should survive in the bowel while such a resistant "putrefactive" organism as *B. welchii*, for instance, can be killed by it, I find entirely incredible.—I am, etc.,

London, W., March 6th.

LAWRENCE P. GARROD.

FINAL NURSING EXAMINATION.

SIR,—I am glad to see that some comment is being made on the examinations for nurses conducted by the General Nursing Council. The following two questions are taken from the last two examinations in fever nursing:

1. A patient has been ordered a hypodermic injection of 1/10th grain of morphia. How would you prepare and administer this from a 1/4th grain tablet?

2. A solution contains 15 grains of chloral in each fluid ounce. The doctor orders ten grains to be given. How much of the solution would you give?

It would be interesting to know the precise reason why such questions are set. They are obviously only simple illustrations of the rule of three, and are no indication of a candidate's knowledge of fever nursing. If an examination is to be held in simple arithmetic it would appear better to have one paper specially for that subject.

There is, however, a much more serious side to the matter, and that is that such questions encourage nurses to dispense dangerous drugs. It is to be remembered that the vast majority of the nurses to be examined in fever nursing have only had two years' experience in a fever hospital. From time to time one reads of disasters occurring from nurses making mistakes with drugs entrusted to them. Here, however, we have the General Nursing Council not simply expecting such partially trained nurses to know the precautions necessary in the administration of dangerous drugs, for these questions will cause the nurses to think that the actual dispensing of such drugs is a part of their duty. Surely this is not the practice in the hospitals of the examiners who have set the papers. It would appear very desirable that the questions set at these examinations should be laid before a properly constituted Board of Examiners in order to prevent such *fauz pas* being made.—I am, etc.,

Iford, Essex, March 6th.

A. H. G. BURTON,
Medical Officer of Health.

SIR,—I have just had my attention called to the two letters in the JOURNAL, from Dr. Bradley (February 13th, p. 305) and Mr. Morton (February 20th, p. 350), with criticisms of the recent nurses' examination papers. May I be allowed to add the point of view of a trained nurse?

I think both these gentlemen are inclined to forget that, when a nurse has finished her training, she does not always remain in hospital, but often works further afield as a private or district nurse. In these cases she often sees the early symptoms of a disease before the doctor is called in and can give him much more intelligent help if she can recognize them. Also she can induce her patient to seek medical help in time.

This especially applies to the third question referred to—that of recognizing the symptoms of a displaced uterus. Although this is not actually mentioned in the examination syllabus (it is mentioned in the original General Nursing Council lecture syllabus for nurses), it is nevertheless one of the conditions which a nurse meets with outside hospital far more than the more serious diseases mentioned in the syllabus.

Any experienced trained nurse will agree with me that many women will far sooner confide their symptoms to a sympathetic nurse whom they know than go straight to a doctor. In this case a nurse's training will help her to recognize the symptoms complained of and to persuade her patient to seek medical aid at once instead of delaying too long as is so often the case.

I agree with Mr. Morton that it is not necessary for a nurse to learn to treat a retroverted uterus herself, but she can be of far more help to the doctor if she knows what sort of treatment he is likely to carry out. Also, in the event of a woman consulting her, it is very necessary that she should be able to help her in the matter of attention to pessaries, etc.

I think the great trouble at present is, not that the nurses are being taught too much, but that in a great many cases, instead of the theoretical work being taught with a view to helping the nurse with her practical work as it should be, the theory and practice are kept entirely separate, which means that the nurse often simply gets a slipshod smattering of each.

I quite agree with Dr. Bradley in his plea for the difficulties of a small provincial hospital, which I fully recognize; but I suggest that, if a nurse trains in a hospital for three years without seeing either of such very common cases as a gastric ulcer or a retroverted uterus, that hospital is hardly worth being called a training school.

May I also remind your correspondents that in all the General Nursing Council examinations' alternative questions are given, so that if a nurse finds one question which she cannot answer she can leave it for another?—I am, etc.,

COMMON SENSE IN RELATION TO DOUBTFUL TUBERCULOSIS.

A Plea for Observation Sections in Sanatoriums.

SIR,—Dr. E. Weatherhead puts very fairly in his letter (February 27th, p. 401) the serious ill effects that may visit a patient who is labelled "tuberculous" but who is not so. There is, of course, the possible good effect of an open-air rest cure, even in a doubtful case, but this is obtained at an unwarranted cost if the patient is associated residentially and intimately with definite open and positive cases of pulmonary tuberculosis. I believe the cumulative and widespread evidence of personal infection by the tubercle bacillus, in constant and heavy doses, has convinced the majority of the profession that close association does play a very definite part in the spread of the disease. The point I wish to stress is that all sanatoriums should have separate sections for "suspects" who are under "observation" and are non-diagnosed and non-notifiable. Unfortunately, such separate accommodation does not generally exist. I know several sanatoriums in the West of England and elsewhere where at least 50 per cent. of the cases are open or "positive," and which have no "observation" wards at all, and where "open" cases and "suspects" live freely together. The authorities shelter themselves under the erroneous dictum that the Ministry of Health will only pay the 50 per cent. of the maintenance costs if the patients are notified as tuberculous, and thus short-sighted physicians diagnose tuberculosis in order to get patients admitted. The Ministry, on the contrary, advises the provision of such "observation" sections as definitely in tuberculosis as in other infectious fevers.

Hence my experience and decided view is that the combination of risks and evil consequences which follow the sending of doubtful cases to sanatoriums, without separate provision for observation, throws a grave responsibility on the medical officer or practitioner in diagnosis. The patient should be kept under close observation until a diagnosis is arrived at, either at the clinic or sanatorium. If the diagnosis cannot be made at the clinic by a combination of all modern methods, including radiological, then admission to an "observation" section of a sanatorium is indicated, without delay.

It is only by training in and practice of accurate diagnosis by up-to-date, thorough, and scientific methods, including radiological, that it will be possible to avoid the distressing and often tragic and discreditable instances of (1) patients dismissed by the doctor as non-tuberculous, or "to come again in six months," when the last stages of the disease render it manifest, and (2) patients who are non-tuberculous suffering the grave risks and serious after-life limitations of those who are notified, and who pass in and out of certain well known sanatoriums.—I am, etc.,

F. G. BUSHNELL, M.D.,
Medical Officer, Plymouth and District Hostel
for Children of Tuberculous Parents; Medical
Officer of Health, Torpoint U.D.C.

March 3rd.

TREATMENT OF SPLENIC ANAEMIA IN YOUNG CHILDREN.

SIR,—In your issue of March 6th (p. 411) is an article by Ashby and Southam entitled "Splenic anaemia of young children treated by splenectomy." They quote three cases of this disease from whom the spleen had been removed, and who recovered. They ignore the effects of the transfusions they also gave, and appear to ascribe the recovery from the disease solely to the operation. The

reference to a control series of cases treated on medical lines contains no statement as to whether these included transfusion.

There is probably no disease of childhood where transfusion has a more dramatic and lasting effect than in von Jaksch's anaemia. It may, indeed, be true that splenectomy is also beneficial, but by their procedure Ashby and Southam have clouded the issue. The only logical deduction that can be drawn on their evidence is that it is possible to remove the spleen with safety in this disease.

Of four cases in my personal experience, three recovered—two after transfusion and one with arsenic, fresh air, and sunlight. One patient who was admitted to hospital with a haemoglobin percentage of 12 died, in spite of several transfusions, with a secondary bronchopneumonia. A surgical operation here would not have been tolerated.

Arguing from the splenic anaemia of adults, splenectomy may theoretically be of use also in von Jaksch's anaemia, but there is as yet no evidence.—I am, etc.,

London, W.1, March 5th. GEOFFREY BOURNE, M.D.

NEPHRECTOMY IN INFANCY.

SIR,—My attention has been drawn by Professor Francis Dixon of Dublin to an error which occurred in my article "Nephrectomy in infancy," published in the JOURNAL on February 27th (p. 371).

He has kindly pointed out to me that he has observed a case of three normally developed kidneys in an adult male subject in the anatomical department of Trinity College, whereas I was unaware that any such case had been recorded. The specimens are described in the *Journal of Anatomy and Physiology*, vol. 45.

Examples of supernumerary kidneys have been reported from time to time, but the accessory organ has been either lobulated or very small.—I am, etc.,

London, W.1, March 4th. A. CLIFFORD MORSON.

LEUCIN CRYSTALS IN URINE.

SIR,—Under some such title a correspondent in your columns nine or ten years ago described what he thought to be leucin crystals occurring in patients who frequently suffered from colds. I write now to confirm this view, and to extend its scope to a great number of disorders other than just colds or catarrhal affections.

Some four or five years ago, during the routine chemical and microscopical examination of urines, I began to notice, about October and November, that patients suffering from catarrhs, colds, etc., gave evidence of the presence of intestinal toxæmia, with or without evidences of disturbed hepatic function—namely, indican +, oxalates +, bile + or —, *Bacillus coli* + or —, together with round or oval opalescent bodies, mostly homogeneous, but often with faint concentric markings and radiating striations, which I was inclined to regard as impure leucin, as it seemed identical with what is figured as such in Simon's *Clinical Diagnosis* (p. 423).

Numerous attempts to get these verified at several clinical laboratories failed, as nothing like what I described was ever found. The only conclusion I could come to was that they had disintegrated while in transmission through the post. Further specimens were sent to an eminent member of the profession, who found what he thought I was describing, and said that they were degenerate epithelial cells, whose nuclei he had been able to stain. Coming from such a source, I took the decision as final, and had to look out for some other explanation for this "degenerate epithelium." It seemed strange, however, that as the patients' symptoms cleared up these disappeared also, and returned the next year almost in as widely "epidemic" numbers as the catarrhs and other illnesses that the cold season brought with it.

During the past few months, when there have been many catarrhs, influenzal cases, rheumatic and neuritic conditions, and dyspepsias of various types, these bodies have returned. I suggest that this is the true nature of these bodies because of two specimens I have seen lately. One showed bodies of varying size in the same field of the microscope (this would not be the case if they were epithelial in origin, which would require them to be of fairly uniform size) and no other cell present. The other showed, beside the amorphous opalescent bodies, chains of tiny rounded globules, sometimes arranged like gigantic streptococci, others in clusters, like gigantic staphylococci. The cases in which these were present were of the most varied description: catarrhs, colds, so-called gastric influenza, dyspeptic cases, heart irregularities, apoplexy,

haemorrhages (epistaxis, menorrhagia, haematemesis), bronchitis, and laryngeal catarrhs, to mention only some of those seen. A recent French writer on infection *versus* anaphylaxis, who remarks how frequently these nasal catarrhs, anginas, etc., are futilely treated with douches and gargles, because they are a result of anaphylaxis caused by indican, seems to be supported by the urinary findings in this series of cases.

The presence of an increased intestinal toxæmia with hepatic disturbance was indicated by the urinary and clinical findings, but whether they were secondary to the naso-pharyngeal condition I could never be certain. The finding of other cases, however, at or about the same period, showing purely abdominal symptoms without catarrhal signs, suggested that a large factor at any rate was the abdominal source.

That certain atmospheric conditions, such as cold, damp, and high barometric readings, can alter the bacterial activity of intestinal germs I have no doubt; how otherwise can one explain "epidemics of appendicitis," using the term to mean the occurrence of many acute cases requiring operation all in a short space of time? The other side of the question—is it due to disturbance of the liver metabolism as a result of chill?—might also help to explain the appearance of these leucin crystals.—I am, etc.,

Darlington, Feb. 1st. R. CHALMERS, M.D., F.R.C.S.Ed.

Universities and Colleges.

UNIVERSITY OF OXFORD.

THE electors of the Weldon Memorial Prize have reported to the Vice-Chancellor that they have awarded the prize to Major Greenwood, F.R.C.P. The prize is awarded every three years to the person who, in the six years preceding the date of the award, has published the most noteworthy contribution to biometric science. Dr. Major Greenwood is Reader in Medical Statistics in the University of London.

UNIVERSITY OF CAMBRIDGE.

At a congregation held on March 6th the degrees of M.B. and B.Chir. were conferred on G. W. Bamber.

UNIVERSITY OF LONDON.

Hutchinson Triennial Prize.

THE subject set for the triennial Hutchinson prize, of the value of £60, open to full students of the London Hospital, is suppuration in the lungs and pleura. The dissertations for the prize must be delivered at the hospital not later than March 31st, 1929. Candidates are eligible to compete until the expiration of ten years from the date of registration as a student of the hospital. The number and importance of original facts will be considered principal points of excellence, the object of the prize being to encourage clinical and surgical work and original investigation. No award will be made if, in the opinion of the examiners, the essays have not attained a sufficiently high standard of excellence. Further information may be obtained from the secretary of the London Hospital Medical Council.

UNIVERSITY COLLEGE.

The annual report for 1926 of the committee of University College states that during the session 1924-25 the total number of students enrolled was 3,033. Of these 2,431 were taking day courses, 388 evening courses, and 214 vacation courses. The day-course students included 520 post-graduate and research workers. Of the total 2,415 came from homes in the United Kingdom, and 230, including 83 post-graduate and research workers, from various parts of the empire. From European countries there were 244 students: Germany 51, Switzerland 39, France 32, Holland 21, Russia 19, Sweden 14, Norway and Poland 11 each, Czechoslovakia 9, Italy 8, Belgium and Denmark 5 each; 52 students came from the United States of America (26 undergraduate, 24 research, 1 evening, and 1 vacation course). From other countries the largest number (41) came from Japan, and of them 11 were doing research work. There were 1,234 students in various stages of degree courses. Of these 295 passed examinations leading to degrees, 299 obtained degrees (244 bachelor degrees, 195 with honours), 55 higher degrees (24 masters, 15 Ph.D., and 16 doctors). The College has for many years provided public lectures, at which the approximate aggregate number of attendances during the session 1924-25 was 14,840.

An appeal for £500,000 in connexion with the celebration of the centenary of the College in 1927 was formally launched about six weeks ago. Of the total amount £225,000 is required for the endowment of teaching, £25,000 for the completion of the Gower Street front, and £30,000 for the provision of a great hall. At the inaugural luncheon at the Mansion House, London, on January 29th, under the chairmanship of Prince Arthur of Connaught, gifts to the amount of £39,000 were announced.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND.

At the monthly business meeting of the College, held on March 5th, the President duly admitted Joseph O'Mahony to the licences in medicine and midwifery. The following candidates have passed an examination for the Conjoint Diploma in Public Health: W. McCarthy, J. I. E. McCormack.

Medico-Legal.

LUNACY LITIGATION.

THE liability of a medical practitioner to an action for damages at the instance of any mental patient whom he has certified in pursuance of the Lunacy Acts raises the question whether the medical practitioner is at present afforded sufficient protection against litigation which is not merely vexatious but may be ruinous to his professional career. The South African Department of Justice recently issued a circular¹ to the effect that as medical practitioners who certify patients under the Mental Disorders Act of that Dominion do so in discharge of a duty which is imposed on them by statute, the Minister of Justice has agreed that they should be dealt with in the same manner as a Government official if civil proceedings are instituted against them as a result of their signing such certificates. There is this proviso, however—that the Minister of Justice retains in each case the right to decide whether there are good reasons for holding the medical practitioner concerned personally liable for any costs or losses incurred or resulting from such proceedings. In this country Section 330 of the Lunacy Act of 1890 is the medical practitioner's shield against vexatious litigation. Subsection (1) says he shall not be liable to any civil or criminal proceedings, whether on the ground of want of jurisdiction or on any other ground, if he has acted in pursuance of the Lunacy Acts in good faith and with reasonable care. Subsection (2) goes much further. Such proceedings can be stayed upon summary application if the court is satisfied that there is no reasonable ground for alleging want of good faith or reasonable care, upon such terms as to costs as the court may think fit. Consequently the medical practitioner may meet such litigation at two stages—first, when it is still interlocutory, by throwing the onus of proving a *prima-facie* case of absence of good faith or reasonable care on to the plaintiff; and secondly, if the action is not then stayed, by pleading at the trial that he has acted *bona fide* and with reasonable care. It can scarcely be doubted that discharged mental patients would be a productive source of vexatious litigation were it not for the existence of Subsection (2) of Section 330. But are the safeguards provided by that Section adequate?

Hume-Spry v. Smith and Watson.

A striking illustration of the actual working of Section 330, Subsection (2), was provided in the Court of Appeal on February 26th, when Lords Justice Bankes, Warrington, and Atkin concurred in allowing the appeal of Captain F. Hume-Spry against the decision of a Master in Chambers (Master Ball), which had been affirmed in Chambers by Mr. Justice Bateson, granting a stay of proceedings in an action against Dr. R. Percy Smith and Dr. A. H. Watson for damages for alleged negligence in certifying Captain Hume-Spry to be a lunatic in pursuance of the Lunacy Acts. It appeared that Master Ball stayed the proceedings because he considered the defendant medical practitioners had acted in good faith and with reasonable care, but the Court of Appeal construed Subsection (2) to mean this: That the duty of the Master in Chambers was, not to decide whether the defendants had or had not acted in good faith and with reasonable care in pursuance of the Lunacy Acts, but to decide whether the plaintiff had disclosed a *prima-facie* case of negligence to go to a jury. Here the plaintiff had produced affidavits supporting his contention of sanity from Dr. Risien Russell and Sir James Purves-Stewart, showing clearly a *prima-facie* case. Therefore, it might well be that in lunacy litigation doctors who have a defence *prima facie* may still be put to heavy law costs because Subsection (2) only affords protection where the plaintiff has not disclosed a *prima-facie* case of negligence. The question to which Master Ball and Mr. Justice Bateson addressed themselves in Chambers is the one which will ultimately be submitted to the jury: Did the medical men act in good faith and with reasonable care? It is the exact converse of the one to which the Court of Appeal addressed themselves: Has the plaintiff disclosed a *prima-facie* case of negligence? The affirmative answer in Chambers to the query

of *bona fides* and reasonable care shows that in the Hume-Spry case there is, *prima facie* at all events, a defence. Subsection (2), therefore, only protects doctors from frivolous and vexatious litigation. That appears to be the moral of the proceedings in the Court of Appeal on February 26th.

ALLEGED NEGLIGENCE.

Norris v. MacWilliam.

THE hearing took place in the King's Bench Division before the Lord Chief Justice and a special jury, on March 3rd and subsequent days, of an action brought by Mrs. Florence Norris, the wife of a tourist clerk living at Thornton Heath, against Dr. W. A. MacWilliam of Norbury, for damages for an alleged breach of contract and for personal injuries resulting from the alleged negligence of the defendant in treating her during childbirth. There was a claim of £430 for special damages. The defendant denied negligence, and counter-claimed for £8 8s., his fees for attending the plaintiff.

The jury returned a verdict for the defendant both on the claim and counter-claim, and judgement was entered accordingly.

Mr. Charles, K.C., and Mr. Humphrey Edmunds appeared for the plaintiff; Mr. Neilson, K.C., and Mr. H. C. Dickens (instructed by Messrs. Hempsons on behalf of the Medical Defence Union) for the defendant.

Mr. Charles, in his opening, said that on May 10th, 1924, Mrs. Norris, a young married woman, gave birth to her second child, and that Dr. MacWilliam, who was engaged to attend her, arrived at the house shortly afterwards. The confinement was not an easy one, and on May 12th the plaintiff's temperature rose to 101° F., and she was seized with a fit of shivering. The defendant did not call as he should have done. When he did come, on May 13th, he was informed by the nurse of the plaintiff's symptoms, but apparently he did very little. On May 21st the plaintiff's temperature rose to nearly 105°, and the nurse was so alarmed that she administered a douche. The doctor did nothing except give the plaintiff two bottles of medicine during all this time. On May 27th Mrs. Norris had an extreme pain in her right groin and the doctor prescribed medicine which seemed to do less than good, and he caused the plaintiff to walk from room to room, although she really needed complete rest, she was in such agony. On June 18th the plaintiff, with the nurse, went to Clacton, where two local doctors diagnosed that she was suffering from puerperal sepsis, requiring an immediate operation. She returned to London and a serious operation was performed, resulting in the plaintiff being unable again to bear a child, and this, she alleged, was due to the negligence of Dr. MacWilliam in his treatment of her.

The plaintiff gave evidence in support of her counsel's opening statement. Cross-examined by Mr. Neilson, she said Dr. MacWilliam attended her at the birth of her first child. She admitted she had a bad time the night before she went to Clacton, and that it might have been prudent to have asked Dr. MacWilliam's permission to undertake the journey. A day or two before she went to Clacton she had been out for a two hours' motor ride.

Mr. H. C. Norris, the plaintiff's husband, said Dr. MacWilliam said a temperature of 104° was nothing to be alarmed over if the pulse was not very fast.

Mrs. Brock, certified midwife, said Dr. MacWilliam examined the plaintiff internally and externally two or three times before her journey to Clacton. She agreed that Mrs. Norris was unwise to undertake a four hours' journey to Clacton in the condition she was then in.

Dr. Percy Coleman and Dr. J. Coxhead Cook, who examined the plaintiff at Clacton, said they found an abscess in the region of the ovary and advised an immediate operation. Dr. F. G. Pailthorpe of Norbury said that the patient's condition precluded the possibility of her having another child.

Mr. Neilson, opening for the defence, said there were two schools of thought among doctors on the method of treatment of cases of childbirth, and the defendant was with those who believed that after a childbirth the subsequent healing processes should be left to Nature unless it became apparent that the professional attendant should interfere. This was a normal birth, and he contended that there was no evidence to justify a charge of negligence.

Dr. MacWilliam said he had been in practice thirty years, and had spent eleven years at Norbury. He had attended over 4,000 maternity cases. The plaintiff's pulse was steady all the way through, and that was a very important point. Had he known she had passed a sleepless night and suffered great pain before starting for Clacton he would not have allowed her to go. Cross-examined by Mr. Charles, the defendant denied that he treated the case too lightly.

Dr. John S. Fairbairn, obstetric physician and lecturer on midwifery at St. Thomas's Hospital, said, from the evidence he had heard and the documents he had seen relating to the case, he thought Dr. MacWilliam had done everything necessary. Both temperature and pulse were important indications; but a high pulse rate was the more important. He would not have dissented from the plaintiff taking an ordinary drive, but when she drove to Clacton a "bumpy" road might have aggravated her condition. There was nothing, in his opinion, to lead Dr. MacWilliam to discover the presence of an abscess in the ovary.

Mr. Ross Wyatt, assistant obstetric physician at St. Thomas's Hospital, also gave evidence on behalf of the defendant.

The jury returned a verdict as stated.

¹ South African Medical Record, January 23rd, 1926, p. 45.

RECORDS OF DANGEROUS DRUGS.

At the Mansion House, before the Lord Mayor last week, Dr. J. C. Kingsbury, who is both a registered medical practitioner and a barrister-at-law, was summoned at the instance of the Director of Public Prosecutions for declining to disclose either in the record that, under the schedule of the Dangerous Drugs Act, 1920, has to be kept, or in the day-book, the name and address of a patient to whom he was supplying morphine. Dr. Kingsbury, who appeared in person, contended that any physician who was supplying the drug under his direct personal control and supervision could not be deemed to be supplying it within the terms of the regulations. After hearing the arguments and Dr. Kingsbury's evidence the Lord Mayor said that he had come to the conclusion that there had been a breach of the regulations, and as he regarded the matter in the nature of a test case he would impose only a nominal penalty of 25 guineas with 10 guineas costs. Dr. Kingsbury informed the Lord Mayor that he would ask him to state a case, and this being so we refrain from commenting on the matter.

Obituary.

GEORGE BOOTH, M.D., M.R.C.S., L.R.C.P., J.P.,
Honorary Consulting Physician, Chesterfield and North
Derbyshire Royal Hospital.

THE death of Dr. George Booth has deprived Chesterfield of one of its principal citizens, and the medical profession in North Derbyshire of a most distinguished member. Dr. Booth passed away on February 18th, after a short illness, in his 86th year, having remained in active practice until a few weeks previously. The son of a minister of the Primitive Methodist Church, he received his early education at Chesterfield Grammar School. Through lack of means, his father having died, he was obliged to begin work as an apprentice in the shop of a Chesterfield pharmacist, where he quickly obtained promotion and became a partner in the business. He had now developed a keen interest in the practice of medicine, and entered as a medical student at the Sheffield School of Medicine and Charing Cross Hospital. He obtained the diplomas M.R.C.S. in 1881 and L.R.C.P. in 1887, graduating, finally, M.D. (Durh.) in 1897. After completing his hospital studentship he began general practice in Chesterfield, and took at once a prominent position in the public, professional, and artistic life of the town owing to his remarkable energy and versatility. He built up a large and important practice in Chesterfield and the neighbourhood, winning the esteem and affection of his professional colleagues. He was the first honorary physician appointed to the Chesterfield Royal Hospital, a position he retained until a few years ago, when he became honorary consulting physician. He freely devoted his time and energy to the interests of the hospital, and much of its successful development and progress is due to his activities. He was a loyal and valued member of the British Medical Association, and a member of the executive committee of the Chesterfield Division from its formation in 1912 until last year, when he retired under the new rule as to periodical retirements. He was invited on more than one occasion to become chairman, but felt that age prevented his accepting the post.

Dr. Booth was elected a town councillor in 1882, subsequently an alderman, and became mayor in 1887, relinquishing his municipal activity only in 1920. He was a member of the Chesterfield School Board in 1871, and chairman from 1880 to 1901. He retained the office of chairman of the managers of the Girls' High School until last year, when on his retirement he was appointed president of the school. He was also vice-chairman of the governors of the Boys' Grammar School for many years, where he helped to start the science and art classes, and was a justice of the peace for the borough and county. The Chesterfield Primitive Methodist Church received his active support and sympathy, and for fifty years he was superintendent of its Sunday school. A musician of wide knowledge, and a no mean performer on the violin and 'cello, he was twice appointed by the Primitive Methodist Church to edit their national hymnal; his own setting of the hymn "Rock of Ages" was sung at his funeral service. He

had also strong sympathies with the Church of England, with which he remained in close association. A most courteous gentleman, a loyal colleague, a gracious and charming personality, a valued counsellor, he will be greatly missed by his professional colleagues in the Chesterfield Division. He was married three times, but leaves no children.

H. W. P.

SUTHERLAND SIMPSON, M.D., D.Sc.,

Professor of Physiology, Cornell University, Ithaca, U.S.A.

WE regret to report the death, on March 2nd, of Professor Sutherland Simpson at Ithaca, New York, U.S.A. Rather more than a year ago he was incapacitated from work by a serious illness from which he never fully recovered.

Sutherland Simpson was an Orcadian by birth, and spent his early years on the small island of Flotta, helping his father on the croft, and, like the other island lads, spending much of his time at sea. During a visit to Leith in 1884 he saw an advertisement in an Edinburgh newspaper which had been inserted by the late Professor Rutherford, who required the services of a laboratory assistant in the department of physiology. Simpson was successful in his application, and so a career which was to end in a famous American university began in the department of medical science, to which he was destined to devote his life. He spent about fifteen strenuous years assisting Professor Rutherford in the work of the department. Edinburgh students of the eighties must have vivid recollections of the part played by Simpson in the lecture demonstrations. The work of the department then centred largely in the elaborately prepared lecture, and the arrangement and successful issue of the demonstrations depended mainly upon the laboratory assistant. The duties of such a post would have overtaxed the strength and strained the good nature of anyone less robust and genial than the young Orcadian. Naturally dissatisfied with his prospects in such a post, he made up his mind to take a regular science course, and, by hard work during any spare time, he was able to take the B.Sc. degree in 1894. Shortly after this he determined to take the medical course, and in 1899 he graduated M.B., Ch.B. (Edin.).

In that year Sir Edward Sharpey-Schafer went to Edinburgh, and on Simpson's appointment as a demonstrator in the department his true life-work commenced under conditions which were most congenial to him. From this time onwards until he was appointed to the chair of physiology in the Cornell Medical School, Ithaca, he was actively engaged in teaching and research in the Edinburgh department. Under the stimulating leadership of the newly appointed head of the department he carried on a large number of important investigations on pyramidal tract degenerations, diurnal variations in the body temperature of different animals, secretion pressure of bile and pancreatic juice (in collaboration with P. T. Herring), and the functions of the thyroid gland, the last mentioned being the subject which was afterwards to occupy so much of his attention in America. He proceeded M.D. (gold medal) in 1901, and D.Sc. in 1903. From 1909 to 1924, as professor in the Cornell Medical School, he devoted himself whole-heartedly to the development of his subject, organizing and equipping excellent laboratories, and always gathering around him a band of keen research workers. During this period his work mainly dealt with the effects of thyroidectomy on growth, but many other problems connected with the thyroid, parathyroids, and pituitary also engaged his attention. A very elaborate piece of research by Boring, on cutaneous sensation after nerve section, was achieved in the physiological and psychological laboratories of Cornell during 1915. Many ingenious forms of apparatus of value both for practical class-work and for research were also devised by his departmental staff. The life, although strenuous, was greatly to Simpson's liking, the open spaces around the college not only being more attractive to him than life in a city laboratory, but the local conditions also enabled him to carry out on a large scale his experiments on thyroidectomy and thyro-parathyroidectomy on sheep and goats.

Professor Simpson's last visit to this country was in 1923,

when he attended the International Congress of Physiology, which met in his old department in Edinburgh. He gave then a most interesting cinematograph demonstration on the thyroidectomized sheep. This visit to the home country he enjoyed immensely, as he was able to spend some happy days again on Flotta, and so to recall the days of his youth. After a short visit to certain Continental schools he returned to Ithaca, and up to the end of 1924 he still continued actively engaged on the thyroid researches which have contributed so largely to our knowledge of this subject. His loss will be deeply felt by his numerous friends, not only in America but also in this country.

He is survived by his widow, a daughter, who is on the staff of the Cornell physiology department, and a son, who is a medical graduate of Harvard.

Dr. EDWARD MOLYNEUX, who died at his residence in Little Neston, Cheshire, on February 11th, received his medical education at University College, Liverpool. He graduated M.B., Ch.B.Vet. in 1889, and in the same year obtained the diplomas of the English Conjoint Board and the L.S.A. He was medical officer of the Garston Accident Hospital for some little time, and also held the posts of house-physician and house-surgeon to the Liverpool Royal Infirmary, as well as assistant demonstrator in physiology and histology, and house-physician to the gynaeccological department of this institution. After subsequently practising in Cressington he removed to Southport over sixteen years ago. His professional duties did not prevent him from taking an active interest in local affairs in that town, and he served as a member of the board of guardians. In 1920 he was elected to the town council as a representative of the Craven ward, and was vice-chairman of the health committee. He was a conservative in politics, and had been chairman of the Southport Conservative Club. Dr. Molyneux was a member of the Southport Division of the British Medical Association.

Dr. GABRIEL MAUNOURY, a well known surgeon of Chartres and formerly president of the French Congress of Surgery, has recently died at the age of 76. He was a brother of the celebrated Marshal Maunoury.

The deaths are reported of Professor Piffle, head of the German Ophthalmological Clinic at Prague, on his 60th birthday, and of Professor Julius von Eröss, a well known Hungarian paediatrist of Budapest, at the age of 70.

THE NATIONAL INSTITUTE FOR THE BLIND.

The annual report of the National Institute for the Blind (224, Great Portland Street, W.1) for the year ended March, 1925, shows a steady progress in the work of that admirable institution. It is the largest institution of the kind working for the blind in any part of the world. Its balance sheet is some indication of its activity, for the grand total of its financial commitments for the year exceeds £300,000.

The institute strives to meet all the needs of the blind not covered by statutory provision, both in the educational and practical fields. It is both a university for the blind and a maid-of-all-work. It includes the publication of Braille embossed books, magazines, and newspapers, and of Moon embossed books and periodicals—Moon type being easily learnt by the aged blind; the preparation by hand of textbooks in Braille for blind students, and the maintenance of a students' library; the publication of embossed music, and of the works of British blind composers; the general welfare of blind musicians; the provision of apparatus for the blind, such as writing machines, mathematical boards, games, Braille watches, models, etc.; the maintenance of three homes for blind babies at Chorley Wood, Southport, and Leamington Spa, a college for blind girls at Chorley Wood, a massage school in London, homes for blind women at Clifton and Brighton, a guest house for the aged blind at Chester, a blind women's hostel in London, and a convalescent and holiday home at

St. Leonards-on-Sea; the relief of the blind poor; training and after-care of the adult blind and of blind ex-service men who are ineligible for pensions, and their blind dependants; the visitation and training of the blind in their own homes; the support of home industries for the blind, including supply of materials at cost price, sale of goods, augmentation of wages, etc.; technical and research work which may tend to lessen the burden of blindness; the employment of the blind; and assistance to local institutions and societies for the blind throughout the country in the form of financial assignments and allocations.

We regret to note that since the publication of this report the institute has lost by death its indefatigable secretary-general, Mr. Henry Stainsby. His memorial is in the institute, which was largely his personal work. It is to be hoped that his successor will be a man of like calibre and devotedness.

ROYAL MEDICAL BENEVOLENT FUND GUILD.

The annual meeting of the Royal Medical Benevolent Fund Guild was held on February 27th at 47, Brook Street, Lady BLAND-SUTTON presiding over a very large assembly of subscribers and their friends. Lady FRIPP, chairman of the council, reported a great increase in activity, necessitating the appointment of a general secretary-accountant to replace Miss Thomson, whose resignation after fifteen years' zealous work was deeply regretted. Reports were given of the development of the various provincial branches of the Guild, some of which, notably Edinburgh, Glasgow, Bath, Cardiff, Reigate and Redhill, and Preston, had made good progress in obtaining new subscribers or in raising funds by means of entertainments or sales. A new branch had been formed at Great Yarmouth. Among the London districts Hampstead and St. Pancras were prominent, and five new districts had been formed—North London, Harrow, Pinner, Barnes, and Mortlake. In the unavoidable absence of Mrs. Scharlieb, M.D., the report of the honorary treasurer was read by Lady BRADFORD. She said that though donations this year had amounted to the record total of £3,753 the amount (£1,288) derived from annual subscriptions, which formed the only really reliable source of income, did not meet the often inadequate help given to older beneficiaries, quite apart from the money required for educational grants. The Care Committee had appealed for a 50 per cent. increase in the monthly maintenance grants to the older beneficiaries, and new subscribers were urgently needed to this end.

Mrs. A. ORMOND, chairman of the Care Committee, in a moving report of cases relieved, gave examples of the benefits conferred on the younger persons, from a grant to enable a girl left fatherless to complete her medical course, to the provision of one square meal a day to a lad apprenticed to a firm of engineers. During 1925 24 girls and 16 boys had been educated entirely or partially at the cost of the Guild. Observation of children living in homes where money is pitifully short has convinced the committee that, where possible, boarding-schools are to be preferred. The depressing atmosphere of such homes, a too limited and monotonous diet, and the absence of any money, even for trivial amusements such as bus rides, are bad for children, and the care-free atmosphere of school life is much more desirable.

Mr. PETT RIDGE and Miss MADGE TITHERIDGE spoke eloquently on behalf of the Guild: and cordial votes of thanks were given to Sir John and Lady Bland-Sutton and to the officers of the Guild.

At the invitation of the Medical Insurance Agency, which has this year again given a donation of £525, a representative of the Guild, in the person of Mrs. Ormond, has been appointed to serve on the subcommittee of the Agency dealing with the education of girl beneficiaries.

Legacies received during the year include £100 from the late Miss E. J. Humby, £200 from the George Macbain Trust, and £300 from the late Miss Constance Turner. The Stock Exchange male voice choir again, in 1925 and in 1926, devoted the proceeds of their annual concert to the Guild, and in 1925 the sum accruing from the third of the successful golf competitions organized by Lady Rigby, under the auspices of the Ladies' Medical Golfing Society, completed the £200 for an annuity scholarship which these competitions were started to provide. Special efforts such as these are of value, not only for the money they bring in, but for the interest they excite in those previously unfamiliar with the work of the Guild. Those who are prepared to help in propaganda work in any form, or to send parcels of old clothes, are asked to communicate with the Secretary of the Guild, 58, Great Marlborough Street, London, W.1.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

THE House of Commons this week resumed discussion of the Air Estimates, commenced that on the Navy Estimates, and took estimates for other expenditure. The report of the Coal Commission and the text of the Government's Economy Bill were published. The second reading of the Bethlehem Hospital Bill was moved on March 8th, but objection was again taken and the bill further postponed till March 29th, nothing being said concerning the purchase of the site for public use.

The text of the Midwives and Maternity Homes Bill, introduced by Dr. Fremantle, was due for issue on March 10th. A new clause has been added to the bill providing for the inspection of maternity homes by county councils or county borough councils, except in the case of public hospitals or of homes controlled by registered medical practitioners. The bill, which has been prepared in consultation with the Ministry of Health, has already been read a second time.

Mr. Tinne and Dr. Fremantle, the mover and seconder of the Births and Deaths Registration Bill, which has also been read a second time, are, in company with Sir Richard Luce, to meet representatives of the British Medical Association at the House of Commons next week to discuss the measure.

The Unionist party's Health and Housing Committee, under the chairmanship of Dr. Fremantle, will next week discuss the operation of Section 46 of the Housing Act, 1925, which deals with compensation for slum clearance.

The Government generally approves the recommendations in the Majority Report of the Royal Commission on National Health Insurance, but sees no prospect of passing any legislation based on them this session, save to provide for the remuneration of insurance medical practitioners after December 31st.

The Parliamentary Medical Committee, with Dr. Fremantle in the chair, received on March 3rd a deputation from the British Medical Association which included Sir Robert Bolam, Dr. H. B. Brackenbury, Mr. Bishop Harman, Dr. H. L. Eason (medical superintendent, Guy's Hospital), Dr. J. W. Bone, Dr. G. W. Kendall, Dr. G. C. Anderson, and Dr. C. C. Lord. The deputation came to present its views on the proposed Opticians Bill. This measure, which has not yet been introduced into the House of Commons, is drafted to establish a register of opticians and to prevent unqualified persons from practising that craft. The members of the deputation were opposed to the bill if it conveyed a right to opticians to diagnose and prescribe in eye disorders, though they did not object to a register of dispensing opticians. In dealing with the provision of ophthalmic benefit under the National Health Insurance Acts, the deputation pointed out that 700 ophthalmic surgeons were already registered as ready to examine panel patients, and that this list could be much extended, because many young medical men were now specializing in ophthalmic work. The Parliamentary Medical Committee determined that before forming an opinion on the Opticians Bill it would arrange to hear a deputation of opticians on March 17th.

Small-pox.

Answering Mr. Compton, Mr. Neville Chamberlain stated that in 1924 the deaths per 100 notified cases of small-pox were 0.35, and in 1925 0.17. For encephalitis lethargica the deaths per 100 notified cases in 1924 were 27.9, and for the first three quarters of 1925 50.6. In reply to Captain Nuttall, Mr. Chamberlain said that during the seven weeks ended February 20th, 1926, 2,200 cases of small-pox were notified in England and Wales. Of these, 1,699 were stated to have been unvaccinated prior to infection by small-pox, while in 12 cases information on the vaccinal condition was not yet available. These figures were subject to revision.

Mr. Trevelyan Thomson asked the Minister of Health whether the English doctors who attended the conference of the commission of members of the Health Committee of the League of Nations at the Hague from January 4th to 7th, to examine questions in connexion with small-pox, alastrim, and vaccinia, were present as representatives of the English Ministry of Health; and, if not, in what capacity they were there. Mr. Chamberlain replied that this conference was convened by the Health Committee of the League of Nations. Sir George Buchanan attended in his capacity of British representative on that committee. Dr. Gordon and Dr. Blaxall were invited by the committee as experts possessing special knowledge and experience of the subjects to be discussed.

On March 8th Sir Kingsley Wood, in reply to Mr. W. Thorne, gave details in regard to the number of vaccinations per cent. of births, small-pox deaths, small-pox rate per 100,000, and the number of deaths from vaccination for England and Wales for the financial years 1921, 1922, 1923, 1924, and 1925 respectively; the small-pox deaths and the rate per 100,000 in London; and the vaccination per cent. of births for Leicester and small-pox deaths in Leicester for the same years. He said that the figures were not

available for the financial years: the information contained in the following table was for the calendar years in question.

	1921.	1922.	1923.	1924.	1925.
ENGLAND AND WALES.					
Successful vaccinations per cent. of births	38.3	40.3	47.8	*	*
Number of deaths from small-pox ...	5	27	7	13	9
Small-pox rate per 100,000 population	0.01	0.07	0.02	0.03	0.02
Deaths certified as due to vaccination	3	4	8	1	3†
LONDON.					
Deaths from small-pox ...	—	20	1	—	1
Small-pox rate per 100,000 population	—	0.44	0.02	—	0.02
LEICESTER.					
Vaccination per cent. of births	2.78	3.0	4.21	3.82	*
Deaths from small-pox ...	—	—	—	—	—

* Figures not yet available.

† Provisional figures.

On March 8th Mr. Groves asked the Minister of Health for figures showing the number of children born, the number vaccinated, and the number in respect of whom certificates of conscientious objection to vaccination had been furnished by the parents from 1920 to 1925. Mr. Chamberlain replied that the following table gave the required particulars for the years 1920 to 1923. The figures for 1924 and 1925 were not yet available.

	1920.	1921.	1922.	1923.
Number of children born ...	958,568	849,060	780,277	758,404
Number of above children successfully vaccinated	378,414	324,864	314,550	362,832
Number of above children in respect of whom declarations of conscientious objection to vaccination were received	416,306	382,157	347,511	280,236

Mr. Chamberlain told General Brooke that he had received suggestions from local authorities that powers relating to vaccination should be transferred to the public health authorities. His own intentions were indicated in the provisional proposals for the reform of the Poor Law.

On March 9th Mr. Groves inquired if the Minister of Health could state whether the medical advisers of his department proposed to make any report in explanation of the higher fatality rate which occurred among vaccinated as compared with unvaccinated cases of small-pox in England and Wales. Sir Kingsley Wood replied that reference to this subject would be made in the next annual report of the chief medical officer of the Ministry of Health.

Colonial Medical Service.

The Secretary for the Colonies was asked by Mr. W. Baker, on March 8th, if he could now state his decision regarding the proposal to appoint a medical director in the Colonial Office to act as a liaison officer between the Crown Colonies and the Civil Research Committee. Lieut.-Colonel Headlam also put a similar question. Mr. Amery replied that he proposed at an early date to appoint, in the Colonial Office, a chief medical adviser, whose duty it would be to advise him on all medical and health questions; and to see that all important information bearing on these matters was collected and circulated. The chief medical adviser, whose coming appointment at the Colonial Office Mr. Amery announced, will not, it is understood, be the head of a medical department, nor conduct research, but, besides advising the Secretary of State, will see all papers of importance, will keep the Colonial Office in touch with the Ministry of Health, and will be available for consultation to medical officers returning from the Colonies.

On March 8th Mr. Snell asked the Colonial Secretary what was the amount of money devoted exclusively to research work in the Crown Colonies and Protectorates for medical, veterinary, or horticultural purposes. Mr. Amery, Secretary for the Dominions, replied that the estimates of the Colonial Governments did not, as a rule, show separately the provision made for exclusively research work under the heads indicated. If Mr. Snell wished it, it would be possible to give him a statement of the provision made in the estimates of some of the larger colonies for typical research institutions, such as the Medical Research Institute in the Federated Malay States.

Tuberculosis.—Dr. Vernon Davies asked the Minister of Health if men invalided from the Army, Navy, or Air Force, suffering from pulmonary tuberculosis, were granted benefits under the National Health Insurance Act. Mr. Chamberlain said all men serving in the forces of the Crown were insured under the National Health Insurance Act, and on discharge became entitled, subject to the ordinary conditions, to all the normal benefits of the Act—namely, medical, sickness, disablement, and maternity benefits. Any discharged man who had been for the necessary qualifying period a member of an approved society which provided additional benefits became entitled to participate in such additional benefits.

Industrial Fatigue.—Answering Mr. Neil McLean, Sir Arthur Steel-Maitland said that tests had been carried out for the Industrial Fatigue Research Board at Glasgow, South Side; Glasgow, Central, Bridgeton; Govan and Springburn. Sir Arthur added that, as was well known by Mr. William Graham, who was chairman of the organization, the tests were extraordinarily effective. The results would be published by the Board in due course.

He understood that the tests of applicants at the Glasgow Employment Exchanges had been completed. Lady Astor asked whether it were not true that these tests had led to great social reforms in other countries. Several hostile supplementary questions were asked from the Labour benches, and Mr. McLean asked the Speaker to understand the resentment felt by members who were consulted in their constituencies by women who had been sent to be medically examined without being told that it was voluntary.

Industrial Accidents.—The Home Secretary states that the number of persons reported as killed during 1925 by industrial accidents in factories, docks, and other premises under the Factory Acts, or in mines and quarries or in the railway service, was 2,471. Those reported injured in premises under the Factory Acts were 158,778. Figures of non-fatal accidents in the other industries mentioned were not yet available.

Silicosis and Fibrosis.—Mr. Cecil Wilson asked the number of men who were not affected by the Silicosis Act but who, when examined by officers of the Home Office during the last five years, had been found to be suffering from silicosis. Sir William Joynton-Hicks said no routine examinations of workers were made by the medical inspectors of factories, but during the period in question sample examinations were made in connexion with special inquiries into the grinding and other industries. Approximately 1,106 workers employed in processes which involved exposure to silica dust, but which did not come under the existing scheme of compensation for the refractory industries, were so examined. Of these, 556 were found to be affected by fibrosis of the lungs, which, he was advised, must be attributed to exposure to silica dust. The degree of fibrosis, however, varied greatly, and so far as could be judged on a clinical examination a large proportion were in the early stage; 528 of the 556 men were employed in the grinding industries, and the remaining 28 at steel works.

Convalescent Homes for Insured Persons.—Mr. Briant asked the Minister of Health if, in considering the distribution of surpluses of approved health societies, he would take into account the necessity of the provision of sufficient convalescent homes. Mr. Chamberlain said it rested with each approved society having a disposable surplus on valuation to decide what additional benefits should be provided for its members out of that surplus. Among such benefits were the provision and maintenance of premises suitable for convalescent homes, and the payment of the whole or part of the cost of maintenance and treatment of members in convalescent homes. The latter was one of the most widely adopted benefits. Societies generally were fully alive to the advantages of convalescent home treatment.

Opium Traffic.—On March 8th, in an answer to Mr. Campbell, Earl Winterton (Under Secretary for India) said that in opening the Council of State, on February 9th, the Viceroy of India made the announcement that the Government of India intended, subject to the approval of the Legislature, to reduce progressively the export of opium to all destinations, so as to extinguish the trade altogether within a definite period, except for strictly medical purposes. This policy would involve a corresponding reduction in the amount of opium produced. The period within which extinction would occur had not yet been fixed, and the position of the cultivators must be taken into account. The new policy, if approved by the Indian Legislature, would go far beyond the international obligations of India. Mr. R. S. Hudson asked if Lord Winterton would see that adequate publicity was given to this decision in those countries where we had been attacked for our opium policy, and particularly in the United States. Earl Winterton did not think that lay within his power. Dr. Fremantle asked if there was any guarantee that China would not take up at once the production of opium which was being restricted in India. No answer was given to this question.

Infectious Diseases.—On March 8th Mr. Whiteley asked the Minister of Health the provisional number of cases of diphtheria, scarlet fever, chicken-pox, pneumonia, enteric fever, small-pox, and encephalitis lethargica notified during the year 1925. Mr. Neville Chamberlain replied that the figures asked for, with the exception of those for chicken-pox, which was not universally notifiable, were, for England and Wales: Diphtheria, 47,723; scarlet fever, 91,357; pneumonia, 55,960; enteric fever, 2,779; small-pox, 5,363; encephalitis lethargica, 2,637. Mr. Whiteley also asked, on March 8th, how many deaths from influenza, measles, diphtheria, scarlet fever, and enteric fever were registered in the year 1925. Mr. Chamberlain replied that reliable figures were not yet available, but the provisional figures for England and Wales, derived from the registrars' quarterly returns, were: Influenza, 12,587; measles, 5,221; diphtheria, 2,716; scarlet fever, 981; enteric fever, 373.

Health of School Children.—Answering a number of questions regarding the establishment or maintenance of open-air schools, Lord Eustace Percy, President of the Board of Education, denied that he was endeavouring to prevent expenditure for these purposes. He also denied that his policy was to discourage the establishment of dental centres by local education authorities. He had particularly asked these authorities to take proposals for orthopaedic treatment into consideration when preparing their programmes.

Artificial Limbs for Pensioners.—Major Tryon informed Mr. Buchanan that twenty-six firms were making artificial limbs for ex-service men under contract with the Ministry of Pensions. All were British with the exception of one American firm. Twelve firms were supplying artificial metal legs.

Voluntary Hospitals Commission.—In reply to Mr. Campbell, Mr. Chamberlain said that, despite the decision of the Government not to adopt the recommendation of the Voluntary Hospitals Commission to provide out of public funds additional beds for voluntary hospitals, he had asked the Commission to continue its work. He desired it both to act as a link between the

Government and the voluntary hospitals and also to keep in touch with the local voluntary hospital committees throughout the country and facilitate communication between them. The Commission would advise him on questions relating to voluntary hospitals, and would collect and circulate information likely to be of assistance to local committees, such as the circular on hospital construction now in course of preparation.

Adoption of Children Bill.—This bill was read a second time by the House of Commons on February 26th, without a division, and was sent to a Standing Committee. During the discussion the Home Secretary said the Government was satisfied that the bill was an experiment well worth making. Mr. Palin referred to the register of adopted children, which the bill proposed should be kept by the Registrar-General, and said he thought a copy of the entry should be deposited with the medical officer of health where the foster-parents lived. These children should be subject to the same supervision on the part of the medical officer of health and his women inspectors as in the case of all working-class children or of children cared for in poor neighbourhoods. An orphan child, if adopted, should not be deprived of medical skill and assistance which the child in a poor neighbourhood had, and such supervision would be an additional safeguard to prevent children being cruelly treated by their foster-parents.

R.A.F.M.S.—During the debate on the Air Estimates, in Committee of Supply of the House of Commons, on March 8th, Mr. Basil Peto said that he had been looking into the separate medical staff of the Air Ministry. He found that the total of the medical staff was 1,377, and the gross cost was £347,500, or, deducting all that was allowed for the part of the medical staff that was paid under other Ministry votes, it was £209,000 net. The real figure was £347,500, and the 1,377 members of the medical staff worked out at 1 for every 26 of the whole personnel of the Air Service. Sir Samuel Hoare, Minister for Air, said that they were trying, even with the existence of the three services—the Army, Navy, and the Air Force—to reduce overlapping. The Air Ministry did not desire to set up hospitals anywhere where Army and Navy hospitals were providing treatment for Air Force officers and men. To-day, in England, there were only three Air Force hospitals, in each case where there were no facilities for the officers and men of the Air Force in the near neighbourhood. There were two hospitals for men and one hospital for officers. In Iraq, where the command was an air command and where the main responsibility was an Air Ministry responsibility, there were no Army hospitals, and the Air Force hospital in Iraq was doing all the work for the British and Indian battalions. Sir Samuel Hoare said that in the previous debate Lieutenant-Commander Kenworthy had challenged the Air Ministry about a dental service. They had no dental service. They used the dental officers of the Royal Army Medical Corps.

Milk and Dairy Produce.—On March 9th Mr. Beckett asked leave to introduce a bill to enable local authorities to produce and supply milk and dairy produce. He explained that he was bringing the measure forward because the interim report of the Food Commission showed that undoubtedly there had been considerable false dealing in the supply of milk and dairy produce. It was of utmost importance that children should have a proper supply of pure dairy produce. Leave to bring in the bill was refused by 222 votes to 129.

Workers and Weights.—Mr. J. Hudson asked the Home Secretary whether he was aware that, though the Woollen and Worsted Textiles (Lifting of Heavy Weights) Regulations, dated July 27th, 1925, required that the maximum weight to be lifted by one man should not exceed 150 lb., beams of 360 lb. and 460 lb. weight which, by reason of the narrow space between the looms, could only be lifted into the looms by two men, were still used at certain mills in Huddersfield. The Home Secretary said he was advised that the regulations did not fix any maximum limits for weights lifted jointly by two or more workers. All they required was that no worker should, by himself, lift by hand any weight exceeding the prescribed limits, and this requirement was enforced at all mills. He had not yet received any representations from the Joint Industrial Council for an extension of the regulations to weights lifted by more than one worker. He was prepared to ask the Joint Industrial Council whether in its opinion there was a flaw in the regulations.

Notes in Brief.

So far as is known, no foreign Power has yet signed either the Opium Agreement or the Dangerous Drugs Convention concluded at Geneva in February, 1925. British ratifications were lodged on February 17th, 1926.

In the financial year 1924-25, £37,882,282 was spent in England and Wales on poor relief. The figure for 1925-26 is not yet ascertained.

In 1924 there were 30,048 convictions for drunkenness in the Metropolitan Police district, and 389 in the City of London. In 1925 the figures were 29,581 and 394 respectively.

The Home Secretary is considering the extension of the Silicosis Act to other grinding trades and to portions of the steel industry.

The committee appointed in 1924, under the auspices of the Sanitary Institute and the Society of Medical Officers of Health, to consider the methods of food handling in this country, have been submitted to the Minister of Health.

Lord Buckmaster has given notice that in the House of Lords he will ask the Government if it will withdraw all instructions given to, or conditions imposed on, welfare committees for the purpose of causing such committees to withhold from married women in their district information when sought by such women as to the best means of limiting their families.

Medical News.

At the meeting of the Metropolitan Asylums Board on March 6th Dr. J. D. Rolleston and Dr. G. A. Borthwick were appointed medical superintendents in the Board's infectious hospitals service. Dr. Rolleston, who has been senior assistant medical officer at the Grove Hospital, Tooting, since February, 1921, took over the duties of medical superintendent of the Board's Western Hospital on March 8th. Dr. Borthwick, at present port medical officer and medical inspector of aliens, Plymouth, will become medical superintendent of the Board's Northern Hospital, Winchmore Hill, in succession to Dr. C. E. Matthews, who will shortly retire on superannuation.

THE Minister of Health received on March 9th a deputation from the Central Committee of Poor Law Conferences. The deputation stated that their desire was to assist and not to obstruct proposals for the reform of the Poor Law. They agreed that the present system led to confusion and overlapping and that some reform was necessary. But they were afraid that the Government's proposals would overburden the councils of counties and county boroughs so that the poor would not get the care and attention which was secured under the present system, and they urged that before the proposals for the reform of the Poor Law, circulated by the Government, were proceeded with, further inquiry should be made into the effect of legislative and social changes which had occurred since the report of the Royal Commission and of the Maclean Committee. The Minister said that he doubted whether any useful purpose would be served by further inquiry. The materials had been thoroughly sifted by the Royal Commission and by the Maclean Committee, and the broad outline of the present scheme was not, he understood, unacceptable to the authorities to whom the control of public assistance was to be transferred. In any event, the proposals he had circulated were only provisional, and his object in circulating them was to get the criticism and help of all bodies entitled to speak on the subject. He thought some inquiry into the principles underlying the Poor Law might be desirable at a later date.

THE January number of the *Revue Franco-Russe de Médecine et de Biologie*, which is published monthly in Paris, and devoted to medical and other scientific progress in Russia, contains an article by Professor Sémachko on the general state of health in Soviet Russia. In Leningrad, whose population in June last year was 1,320,000, the tuberculosis mortality is on the down grade, after having increased by rapid strides between 1911 to 1920; there has been a closely parallel rise and fall in Moscow. Infantile mortality has diminished, not only in the large towns such as Moscow, where the death rate is much lower now than before the war, but also in the provinces, and even in some neighbourhoods, such as Vladimir and Leningrad, where the rate had been previously very high. Elsewhere in this issue of the *Revue* statistical notes are given about the Ukraine; at the beginning of 1925 there were sixty-nine tuberculosis dispensaries and fifty venereal clinics in operation. It is also reported that during the first nine months of 1924 about 23,000 cases of small-pox were notified in the Union of Soviet Republics, as compared with nearly 42,000 during the corresponding months in 1923. In 1925 the number of scarlet fever cases in Moscow had diminished by 40 per cent., as compared with 1924: good results had been obtained by prophylactic inoculation. In Siberian towns there is an average of one hospital bed for 198 inhabitants, and in the country parts one bed for 2,342.

At a meeting of the Society of Medical Officers of Health to be held at 1, Upper Montague Street, Russell Square, W.C.1, on Friday, March 19th, there will be a discussion on cancer. The point of view of public health administration will be introduced by Dr. W. D. Champneys; that of the surgeon by Professor G. E. Gask; that of the research worker by Dr. W. D. Newcomb; and that of the general practitioner by Dr. F. E. Allen. Others who have promised to take part are Mr. C. J. Bond and Lieut.-Colonel A. B. Swallow. The President, Dr. G. F. Buchan, will take the chair at 5 p.m., and the meeting is open to any member of the profession.

A THREE months' course of lectures and demonstrations in hospital administration, together with clinical instruction in infectious diseases for the D.P.H., will be given by the medical superintendent, Dr. E. W. Goodall, at the North-Western Hospital, Hampstead, N.W.3, on Mondays and Thursdays at 4.45 p.m. and alternate Saturdays at 10.30 a.m., commencing Thursday, April 8th. The fee for the course, which complies with the requirements of the revised regulations of the General Medical Council, is £4 4s., and £3 3s. for the course under the old regulations.

SIR HAROLD STILES has been elected into the Athenaeum under Rule II of the club, which empowers the annual election of persons of distinguished eminence in science, literature, the arts, or for public service.

At the annual meeting of the Society for the Study of Inebriety, to be held at 11, Chandos Street, W.1, on Tuesday, April 13th, at 4 p.m., Sir William Willcox will open a discussion on the prevention and arrest of drug addiction.

MR. H. W. CARSON will lecture on hernia for the Fellowship of Medicine on March 18th at 5 p.m., at 11, Chandos Street; the lecture is free to members of the medical profession. From March 15th to 27th the Brompton Hospital will hold an all-day course on the various forms of pulmonary diseases. At the London School of Hygiene and Tropical Medicine bi-weekly demonstrations during four consecutive weeks will be given at 2 p.m. by Dr. Low and Dr. Manson-Bahr, commencing on March 16th. The Hampstead General Hospital has organized a late afternoon course (4.30 to 6) with systematic teaching in all departments. From April 14th to May 5th Dr. Heald will give four lecture demonstrations on successive Wednesdays at 5.15 p.m., at the Royal Free Hospital; on recent advances in medical electrical treatment. St. Mark's Hospital will hold an intensive course in proctology from April 19th to 24th, with daily sessions from 10.30 a.m. to 6 p.m., including Saturdays. As the course will not be given unless ten entries are received by April 12th, early application is requested. Copies of all syllabuses and of the general course programme may be had from the Secretary of the Fellowship of Medicine, 1, Wimpole Street, W.1.

THE annual meeting of the Elizabeth Garrett Anderson Hospital, Euston Road, N.W., will be held on Monday, March 15th, at 3 p.m. The chair will be taken by the Countess of Carlisle, and Lady Barrett, M.D., M.S., will speak.

THE next meeting of the North-Western Tuberculosis Society will be held in the surgical theatre of the Medical School, Liverpool, on Thursday, March 18th, at 3 p.m., when the Vice-Chancellor (Dr. Adams) will read a paper. Medical practitioners and students interested in tuberculosis are cordially invited.

THE annual meeting of the Mental After-Care Association will be held at the Fishmongers' Hall, London Bridge, E.C., on Tuesday, March 16th. The chair will be taken by Sir Charles C. Wakefield, Bt., president of the association, at 3 p.m.

THE Secretary of the Department of Scientific and Industrial Research announces that the department has recently established a small research laboratory at Dudley House, Endell Street, in the vicinity of Covent Garden fruit and vegetable market. The laboratory will work in close connexion with the Low Temperature Research Station, Cambridge, which is the headquarters of the fruit and vegetables section of the department's organization for food investigation. The object of the laboratory is to bring the station into closer contact with the trade in fruit and vegetables, and with the practical aspects of the problems of their transport and storage.

WE are asked to state that hospitals in the County of London or within eleven miles of St. Paul's desiring to participate in the grants made by King Edward's Hospital Fund for London for the year 1926 must make application before March 31st to the honorary secretaries of the Fund, 7, Walbrook, E.C.4. Applications will also be considered from convalescent homes which are situated within the above boundaries, or which, being situated outside, take a large proportion of patients from London.

MARTIN HOPKINSON AND CO., LTD., announce for early publication *Medical Aspects of Birth Control*, edited by Sir James Marchant, and containing contributions by Dr. R. C. Buist, Dr. Letitia Fairfield, Dr. Arthur Giles, Professor Leopold Hill, Dr. H. Crichton Miller, Sir Arthur Newsholme, Sir John Robertson, and Dr. Mary Scharlieb.

THE RIGHT HON. STEPHEN RONAN, lately Lord Justice of Appeal in Ireland, has left estate valued for probate at £83,907. After making several bequests he directed that the bulk of the property should go to the Medical Research Council for assisting and promoting scientific research, and, without limiting the discretion of the Council, he expressed the wish that special attention should be given to the relief, cure, and prevention of physical pain by physical means.

DR. THOMAS LAWSON CRAIG has been appointed a member of the Executive Council of Gambia, and an official member of the Legislative Council of that colony.

THE monument to the 323 French pharmacists killed in the war was recently unveiled at the Paris Faculté de Pharmacie by M. Painlevé in the presence of M. Lapie, Rector of the Académie de Paris, and Professor Radais, Dean of the Faculté de Pharmacie.

PROFESSOR CHARLES RICHET of Paris has recently been nominated Grand Officer of the Legion of Honour.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the **BRITISH MEDICAL JOURNAL** alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the **BRITISH MEDICAL JOURNAL** must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the **JOURNAL**, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the **BRITISH MEDICAL JOURNAL** are **MUSEUM 3361, 3362, 3363, and 3364** (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are:

EDITOR of the **BRITISH MEDICAL JOURNAL**, *Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER

(Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Mediscera Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Reclillus, Dublin*; telephone: 4737 Dublin), and of the Scottish Office, 6, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 4361 Central).

QUERIES AND ANSWERS.

INCOME TAX.

"T. D. N." will find that the point raised in his previous question was further discussed in our reply to "J. A. S." and "A. M. I." in our issue of February 27th. At present we are unable to assist him further, but will keep the matter before us in the hope that we may be able to do so at a later date.

A. B. and C. are in partnership; B replaced a car in 1924 and A in 1925, claiming allowances of £390 and £212 respectively. They have since claimed depreciation allowances (in respect of the new cars, of course), presumably for 1925-26, and the Inspector, in making that allowance, has cancelled the previous *general* allowances to the extent to which they affect the 1925-26 assessment.

In an old Scottish case, *Caledonian Railway Company v. Banks* (18 Sco. L. R., 85), the judges seem to have laid down the principle that renewal expenditure and depreciation cannot be allowed simultaneously in arriving at the same assessment. The firm attracts by law one single assessment, and therefore it seems to follow that where depreciation is claimed and allowed the renewal expenses are not allowable. So far as we have been able to ascertain the practice approved by the Board of Inland Revenue, it would appear that they are willing to concede the point, so far as concerns those years for which the figures enter into the average for 1925-26, but not for future years; in other words, that they would in such a case as this be willing to see the simultaneous allowance of depreciation and of renewal deductions where the expense was, in fact, incurred before the books were made up for the practice at April 5th, 1925, but not such depreciation and subsequent renewals. If we have correctly interpreted the attitude of the Board, A, B, and C's inspector of taxes will apparently be able to obtain authority to restore the cancelled deductions for renewals.

"E. S. B." poses a set of facts somewhat similar to those referred to by A, B, and C, but in this case one of the partners renewed his car after the books had been made up for the year 1925, and the account first affects the financial year 1926.

The old car was presumably replaced because it had become obsolete for its purpose; if so, we are of opinion that an obsolescence allowance can be claimed in respect of it—Rule 7, Cases I and II, Schedule D—representing the net cost of renewal less the amount of depreciation allowed on it, in income tax assessments. This, however, will not affect the 1925-26 assessment.

LETTERS, NOTES, ETC.

Dr. S. D. BHABHA (Greenwich), whose account of the *Spies-Drager apparatus* was printed in the **JOURNAL** of January 16th, writes to inform our readers that he has severed all connexion with the clinic mentioned in that note.

INVESTIGATION OF STATUS LYMPHATICUS.

Dr. W. HOWEL EVANS, secretary of the committee undertaking a collective investigation of status lymphaticus, asks us to correct a mistake in the notice sent to us by him and published in our issue of February 27th (p. 395). The interim report of the original investigation was published in the *Journal of Pathology and Bacteriology* for January, 1925—not April, 1925.

INDIVIDUAL OVERDOSE OF ULTRA-VIOLET RAYS.

Dr. ELIZABETH M. ANDERSON (London, W.) writes: With reference to Dr. Ferguson's letter in the **JOURNAL** of February 27th (p. 402), in which he suggests that cataract may be due to ultra-violet and not heat rays, as formerly supposed, I should like to point out that the available evidence is strongly opposed to this view. Dr. Ferguson mentions the incidence of cataract among glass workers, iron smelters, and the like, but the open furnaces to which these workers are exposed emit chiefly heat rays, the ultra-violet rays being negligible in amount or absent. In the tropics, where cataract is of frequent occurrence, the chief constituent of the solar spectrum is heat, the actinic rays being filtered out by moisture. It is well known that dogs who are allowed to sit before domestic fires develop cataract, yet no actinic rays are given off by coal. In the Alps, where ultra-violet radiations are present in comparatively large amounts, the incidence of cataract is no higher than in smoky towns, where they are practically absent. Lastly, in certain cases of incipient cataract, actinotherapy has been used with benefit as a remedial agent.

SUNSHINE RECORDS.

Dr. H. D. BISHOP (M.O.H. States of Guernsey) writes: Of the eighty-two stations recording sunshine recognized by the Meteorological Society, there were only eight that recorded more than 1,900 hours of bright sunshine during the year 1925. They were as follows:

Guernsey	1,999 hours.
Woolthing	1,956 "
Salcombe	1,955 "
Plymouth	1,923 "
Jersey	1,923 "
Littlehampton	1,915 "
Paignton	1,912 "
Teignmouth	1,906 "

All these stations are situated in the English Channel or on the south and south-westerly coasts. The average amount of sunshine in Guernsey during the past thirty-two years was 1,905 hours, a figure considerably exceeding that of all other English stations.

A SCHOOL FOR MYOPE.

We are informed by a leading London ophthalmologist that Mrs. Bridge, B.A., formerly principal of a school in Brighton, has opened a school for myopes at the Manor House, Pildown, near Newick and Uckfield, Sussex. The aim of the school is to give defective eyesight. The teaching is largely adapted wherever possible. Much and sedentary work is reduced to a minimum, and is built for the purpose and suitably adapted in the L.C.C. myope schools are used. The curriculum includes dancing, eurythmics, musical appreciation, and certain handicrafts, beside the usual English subjects and French. Advantage is taken of the wireless and of good gramophone records. Outdoor occupations and interests and simple home duties alternate with the ordinary lessons, so that the time which may not be spent in reading is both usefully and happily filled. At present only ten children can be received.

CARS ON LOAN DURING REPAIRS.

THE Medical Insurance Agency some two years ago decided as a result of many inquiries to initiate a scheme by which the expert advice of a responsible firm of motor engineers should be available without cost to members of the medical profession. In the report of the Agency at the time the hope was expressed that this service would prove of considerable use to the profession, and experience since then would seem to prove that it is keenly appreciated by medical motorists. It has now been found necessary to develop the scheme beyond the original limits. Egerton and Co. of Bond Street have now sent a fleet of cars for loan while repairs to doctors' cars are being carried out at their works.

BURGUNDY AND GOUT.

Dr. P. D. CAMERON (Wellington, N.Z.) writes with reference to the note on "Wine and gout" by our Paris correspondent (*Journal*, December 5th, 1925, p. 1036): The question arises: Does the Australian red burgundy produce the same toxic effect in gout as the French wine? It would be interesting to find out whether geographical considerations or some innate quality of the wine is the factor concerned.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 43, 44, 45, 46, 49, and 50 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 47 and 48.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 51.

A British Medical Association Lecture

ON

DIET AND DISEASE,

WITH SPECIAL REFERENCE TO THE TEETH, LUNGS,
AND PRE-NATAL FEEDING.*

BY

EDWARD MELLANBY, M.D.CANTAB., F.R.S.,

HONORARY PHYSICIAN, ROYAL INFIRMARY, SHEFFIELD; PROFESSOR OF
PHARMACOLOGY, UNIVERSITY OF SHEFFIELD.

(With Special Plate.)

EIGHTEEN months ago I delivered a British Medical Association Lecture at Bradford^{1a} in which I discussed the subject I was actively investigating at the time—namely, the part played by modern dietary in the production of disease as found in this country. I should not have chosen the same subject for this evening's discourse were it not that it is still being intensively investigated all over the world, with results that only emphasize its importance.

Modern experimental work on animals, backed up by clinical observation, has brought to light the fact that the dietary of the people of this country is defective in two important respects: (1) that it includes too little of the substances which contain fat-soluble vitamins, and (2) that it contains relatively too much cereal. Each of these dietetic mistakes tends, among other things, to bring about a certain pathological defect of structure and function in the body, so that their combined influence in this respect is very great and produces widespread disability.^{1a, b, c} For instance, one of the fundamental effects of a fat-soluble vitamin is to stimulate calcification of bones and teeth, while, on the other hand, excess of cereal in the diet interferes with the calcification of these organs. It can be imagined, therefore, how potent must be the destructive action on developing bones and teeth of a diet deficient in calcifying vitamin and containing an excess of cereal. The meagreness of the sunshine in this country and its poor quality so far as ultra-violet radiations are concerned only serve to make matters worse; for, arising from the observations of Huldchinsky² on the effect of ultra-violet radiations on the calcification of bones of rachitic children, we now know that deficiency of antirachitic vitamin in the diet can be made up to some extent by exposure of the body to ultra-violet light, while I have shown elsewhere that excess of cereal in the diet, which interferes with bone calcification, can also be antagonized by exposure to these rays.^{1c}

To-night I propose to return once more to the same subject, and, by other illustrations of the action of these dietetic factors on the body, try to drive home, not only how widespread are the diseases for which these specific dietetic defects are responsible, but also show that it is only by feeding in such a way as to avoid these defects that success can be obtained in the control and elimination of much illness.

TEETH.

I propose, first of all, to deal with the subject of the teeth, and to provide some evidence obtained by May Mellanby^{3a-c} which suggests strongly that much of the dental defect of this country is due to the dietetic mistakes mentioned above. Incidentally the results also indicate the means for combating this serious state of affairs.

It will be clear that if the fundamental cause of dental defect is due to the fact that the dietary of the people in this country is exceptionally low in calcifying properties, then the teeth ought to be badly formed. The test can be made at once. Before, however, dealing with the point, it may be well to state that the ordinary accepted teaching by dental authorities of the structure of, for instance, children's teeth in this country is that, on the whole, they are well formed, only something of the order of 2 to 3 per cent. being recognized as defective in structure. This, if true, would at once disprove the suggestion made above as to the cause of dental defect. But is it true? The 2 to

3 per cent. of defect observed in the deciduous teeth of children are cases of gross hypoplasia of the enamel, smaller abnormalities being passed as normal. It was only when teeth were examined microscopically after being ground down to thin sections that the real structure of the teeth was appreciated and correlated with the naked-eye appearance of the enamel. When this was done it was at once evident that a large proportion of human deciduous teeth were badly formed—not the 3 per cent. suggested, but something like 80 to 90 per cent.^{3b} The following table sums up the results as to the structure of children's temporary teeth after being ground down and examined microscopically.

TABLE I.—Relation between Structure and Caries in the Teeth of Children.

Type of Tooth.	Number Examined.	Good Structure.		Defective Structure.	
		No Caries.	Caries.	No Caries.	Caries.
Incisors ...	100	53	11	1	30
Canines ...	70	5	0	25	40
Molars ...	466	2	11	2	451
Total ...	636	65	22	28	521

The different ratios of abnormal to normal teeth in the various types is interesting. In the case of the molars, for instance, only 13 out of 466 teeth examined were well formed, while in the case of the incisors no less than 69 per cent. were of good structure. It will be also noticed that there was some correlation between the structure of the teeth and caries, for out of the 636 teeth examined 521 were of defective structure and carious, while 65 were of sound structure and non-carious. That is to say, 586 of these 636 teeth, or 92.14 per cent., were in agreement with the hypothesis that a sound tooth is less liable to caries and an imperfectly formed tooth more likely to be carious. Of the 636 teeth, 50, or 7.86 per cent., were in a condition opposed to this generalization. This subject has been discussed by May Mellanby elsewhere,^{3d} and it was pointed out that the exceptions could be explained by the fact, which can also be demonstrated experimentally, that even after eruption the reaction of the teeth to harmful stimuli can be varied by the same dietetic influences which control the formation of the teeth. Thus a badly formed tooth can be made to resist more potently if the diet is made good, whereas the resistance of a well formed tooth is lowered by a defective diet.

The point I wish to make now, however, is that a very large percentage of human deciduous teeth are badly formed, and not the 2 or 3 per cent. as usually stated. In Figs. 1 and 2 can be seen cross-sections of two molars of children: Fig. 1 is a photograph of a perfectly formed molar tooth—a rarity nowadays in this country; the structure of the tooth in Fig. 2 is obviously very imperfect, and a small spot of caries is evident, yet this tooth was described by a dental surgeon as well formed judging by its external macroscopic appearance.

It is clear that children's deciduous teeth in this country are not only very susceptible to caries, but that they are very defective in structure.

The question now arises, Can the structure of teeth be controlled experimentally by diet during development, and, if so, are the dietetic factors controlling the formation of teeth of the same nature in children as in experimental animals? It is now possible, according to the experimental work of May Mellanby, to produce any degree of perfection or imperfection in the structure of the teeth of dogs by means of the diet eaten during the development of the teeth. The most important variables of the diet that are altered to bring about these differences include (1) the amount of fat-soluble vitamin,^{3a} (2) the variation in the amount and type of cereal eaten,^{3c} and (3) exposure of the animal, or in some cases the food, to a source of ultra-violet radiation.^{3e} The more deficient the diet is in the calcifying vitamin, the more it consists of cereal, especially oatmeal, and the less the animal is exposed

* Delivered to the Mid-Cheshire Division, November 12th, 1925.

to ultra-violet radiations, the worse formed will be the teeth. On the other hand, the more the fat-soluble vitamin and the less the cereal eaten, and the greater the exposure of the animal to ultra-violet radiations, the better formed will be the teeth. These facts are demonstrated in the illustrations (Figs. 3, 4, and 5), which are a few examples showing the effect of these dietetic and environmental factors in dental structure. For instance, the difference between the teeth and jaws in Fig. 3 is simply due to the fact that the diet of A contained some cod-liver oil, which is a rich source of calcifying vitamin, the diet of B contained a corresponding quantity of butter with a smaller vitamin content, whereas the diet of C was very deficient in this vitamin, as linsed oil formed the fat content of its diet. Except for these differences everything in the diet and environment of these three puppies, who were members of the same litter, was constant.

The destructive effect of cereals on teeth formation, and especially that of oatmeal, is seen in Fig. 4. Except in the case of A, the diets of these animals, though deficient in fat-soluble vitamins, were constant in this respect, and the variable tested was the cereal. It will be seen that when oatmeal was the cereal eaten (Fig. 4, B) the teeth were very badly formed. The abnormality was least when white flour was eaten (Fig. 4, C), and rather worse when wheat germ was substituted for 10 per cent. of the white flour (Fig. 4, D). Even the potent action of oatmeal, however, was completely antagonized by 10 c.cm. of cod-liver oil eaten daily by the dog whose jaw is represented in Fig. 4, A. The diets of the animals whose teeth are represented in Fig. 4, A and B, both contained oatmeal and were identical in other respects except that 10 c.cm. of cod-liver oil daily was eaten by A, and 10 c.cm. of olive oil by B. The tooth illustrated in Fig. 4, A, is perfect in structure.

The effect on the structure of the teeth of exposing an animal to a source of ultra-violet radiations can be seen in Fig. 5 (A and B). Both of the animals whose jaws are represented in Fig. 5 were brought up on identical diets deficient in the calcifying vitamin, and lived under the same conditions, the only difference being that one (Fig. 5, B) was exposed thrice weekly for twenty minutes to the rays of a mercury vapour lamp. The improvement in the calcification of the teeth produced thereby is obvious.

I have now shown you some evidence which indicates (1) that the deciduous teeth of children are for the most part badly formed, and (2) that the structure of dogs' teeth can be controlled at will by varying certain specific factors of diet and environment. The question arises, How do these facts bear upon the widespread scourge of caries in the teeth of children? One method of answering the question would be to feed children from birth along the lines which animal experiments have indicated as resulting in perfect tooth formation, determining the amount of caries in the temporary dentition, and after the shedding of these teeth from the sixth year onwards grinding them down and examining microscopically. A number of children are being brought up on a diet which, from birth onwards, includes milk, egg-yolk, and cod-liver oil, and up to the present, so far as is known, caries has not appeared in the teeth of these children, but the oldest is now only 5½ years of age, so the test is still in its early stages.

In order to attack the point in a direct fashion with the idea of seeing whether the results obtained with animals could have any bearing on the teeth of children after eruption and after being fully formed, the following preliminary investigation was made by May Mellanby, C. Lee Pattison, and J. W. Proud.⁴ A number of children in an institution were placed on diets which, according to animal experiments, varied in their effect on calcification. Group A were given a diet which contained much milk and some cod-liver oil, less cereal (none of it oatmeal), in addition to other food-stuffs. The diet of Group B contained less milk, more cereal (including oatmeal); while in the case of Group C an intermediate diet from the point of view of calcification, and one which was usually the standard diet of the institution, was given. The children were arranged in groups so that the average age of each group was about the same. Before the diets were started the mouth of each child was carefully charted, the amount and type of hypo-

plasia, the carious points, their extent and degree of hardness, the missing teeth, etc., being noted. After seven and a half to eight and a half months of the diets the condition of the teeth was again charted, and the following results were obtained.

TABLE II.—Effect of Diets A, B, and C on the Initiation and Spread of Caries in Children.

Diet.	Main Dietetic Difference.	New Points of Caries.	No. of Children in Group.	Average New Carious Points per Child.
A	Abundant calcifying vitamin and calcium	13	9	1.4
B	Poor in calcifying vitamin; less calcium, more cereal, especially oatmeal	51	10	5.1
C	Intermediate between A and B	38	13	2.9

It will be noticed that there was nearly four times as much new caries per child on Diet B as in the Diet A group. Since all other conditions of hygiene and mode of living were constant, it is probable that the differences in diet were responsible for the changes in the teeth of the children. If this be true, then the results observed experimentally on the teeth of dogs can be applied to children. The numbers of children observed in this investigation were small; a bigger investigation of a similar nature is necessary before the results can be regarded as definitely established. On the other hand, the amount of difference of developing caries in the various groups seems too big to be explained by inaccuracies of observation and chance.

To sum up, the experimental work demonstrating the conditions of diet which bring about the production of perfect and imperfect teeth in dogs, taken in conjunction with the investigation on children outlined above, makes it almost certain—

(1) that the widespread development of caries in children's teeth is primarily a problem of defective feeding which results in imperfect formation of their teeth;

(2) that the dietetic factors which result in good and bad formation of teeth also confer upon or take away from the erupted teeth of children the power of resistance to the carious process;

(3) that foods containing fat-soluble vitamins, such as milk, egg-yolk, butter, animal and fish fats, and especially cod-liver oil, bring about the formation of good teeth, while cereals, and especially oatmeal, in the absence of calcifying vitamin, bring about the formation of defectively calcified teeth.

THE INFLUENCE OF THE MATERNAL DIET DURING PREGNANCY ON THE SUSCEPTIBILITY OF THE OFFSPRING TO DISEASE.

It would be a generally accepted proposition that the feeding and nutritional condition of a mother during pregnancy modifies the metabolic changes and consequently the well-being of the offspring. If it were only a question of insufficient nourishment supplied to the mother, evidence on this point would be difficult to obtain, for the ability possessed by the maternal organism of sacrificing her tissues for the supply of the fundamental nutriment of the developing foetus is certainly very great. There is, however, better evidence that the malnourished as opposed to the starved maternal organism transmits undesirable weakness and tendencies to pathological change to its offspring.

In the case of rickets, for instance, the maternal factor has appeared so important to some that heredity has even been advocated as the prime cause of this disease. This view has not, however, received much support. The congenital influence which has been stressed by Kassovitz is supported by such facts as the special tendency of premature babies and of twins to develop rickets. It is true, as Schmorl⁵ pointed out, that newborn infants do not show rachitic changes of bone, but it is not improbable that the osteoporotic condition as evident in the craniotables seen in infants soon after birth is a closely related state and may be due to malnourishment of the mother.

Experimentally Korenchevsky and Carr⁷ showed that, in the case of rats, rachitic changes of the bones could be

produced more rapidly, and more certainly, if the mother during pregnancy, as well as the offspring, were fed on diets deficient in antirachitic vitamin and calcium. Hess and Weinstock⁵ have also studied this problem and found that, although improving the diet of mothers during pregnancy and lactation mitigated the development of rickets in infants, it did not prevent it.

In the experiments now to be described the mothers during pregnancy were certainly not insufficiently fed. From the point of view of energy-bearing dietetic constituents the diets were not greatly dissimilar. Even as regards many of the actual foods comprising the respective diets they were identical in kind and in amount eaten. On the other hand, specific differences were introduced of such a nature that one bitch (A) received a diet which, from earlier work, would be expected to result in good health, while the second (B) received a diet which experience had taught would lead to malnutrition. The diets were as follows:

Bitch A.	Bitch B.
Bread (white flour), 150 to 200 grams.	Oatmeal, 100 to 150 grams.
Cod-liver oil, 10 to 20 c.cm.	Olive oil, 10 to 20 c.cm.
Separated milk, 400 reduced to 100 c.cm.	Separated milk, 400 reduced to 100 c.cm.
Meat, 100 grams.	Meat, 30 to 100 grams.
Yeast, 15 grams.	Yeast, 15 grams.

These animals lived throughout the experimental period under identical conditions and became pregnant at approximately the same time, the father being the same in each case. The diets were started in February, 1923, and continued throughout pregnancy, which ended on June 6th and 11th respectively, and during the period of lactation, which lasted until July 23rd and 28th, when the progeny in each case were removed from the mothers and lived separately.

After weaning, the diets were so arranged that two puppies (one puppy from each litter) were given the same food. The following table illustrates the conditions of the experiments. All puppies received the same amount of lean meat, separated milk, orange juice, salt, yeast, together with the special substances indicated in the table for each puppy.

TABLE III.

No. of Puppy.	Diet Variables.	Mother.	Father.	X-Ray Result.
698	Oatmeal, linseed oil, and 0.5 gram calcium carbonate	A	R	Nearly normal.
709		B	R	Moderately bad rickets.
699	Oatmeal and linseed oil	A	R	Slight rickets (Fig. 6, A).
706		B	R	Very bad rickets (Fig. 6, B).
730	Oatmeal and cod-liver oil	A	R	Normal bones.
704		B	R	Normal bones.
701	White flour and cod-liver oil	A	R	Normal bones.
703		B	R	Normal bones.
703	Oatmeal and cod-liver oil, heated and oxygenated 72 hours	A	R	Slight rickets (Fig. 7, A).
707		B	R	Bad rickets (Fig. 7, B).

The only results that need be referred to here are those of the dogs on diets which would be expected to interfere most severely with bone calcification. These are 698 and 709 (oatmeal, linseed oil, and calcium carbonate), 699 and 706 (oatmeal and linseed oil), and 703 and 707 (oatmeal and cod-liver oil, heated and oxygenated seventy-two hours). Since there is little or no calcifying vitamin in linseed oil, and that present in cod-liver oil is destroyed by seventy-two hours' heating and oxygenation, none of these diets contained the necessary amount of vitamin. The results obtained in the case of 699 and 706 (oatmeal and linseed oil) can be seen in Fig. 6 (A and B), where the radiographs after ten weeks of the diet are shown. It will be seen that 706 (defectively fed mother—Fig. 6, B) has advanced rickets in the radiograph, whereas the radiograph of 699 (well fed mother—Fig. 6, A) shows only slight rickets at this time. Since the only difference in the life-history of these two dogs is that the mother of

one (706) was defectively fed during pregnancy and lactation, while the mother of 699 had a good, strongly calcifying diet, it is probable that this is responsible for the increased susceptibility of 706 to develop rickets as compared with 699.

A similar result was obtained with 703 and 707, where heated and oxygenated cod-liver oil was the fat eaten by both. It will be obvious in Fig. 7, A and B, that 707 (defectively fed mother—Fig. 7, B) has developed more severe rickets than 703 (well fed mother—Fig. 7, A), and the reason for this is probably the same as in the case of the preceding pair. Animals 698 and 709 (radiographs not shown) reacted in the same way: 709, having the defectively fed mother, developed much more severe rickets than 698 (well fed mother).

It was a matter of interest to know how long the influence of the defective diet of the mother would be evident in the offspring, and more information was obtained from other puppies in these litters in the following way. Animals 701 (well fed mother) and 708 (badly fed mother), after weaning, were given a good diet containing an abundance of antirachitic vitamin. This continued for four months, and by this time the puppies were in excellent condition and about 6 months old. The diet of each was then changed to a defective one by the substitution of oatmeal for white flour and olive oil for cod-liver oil. After six weeks of this defective diet it will be seen that the bones of 708 (defectively fed mother—Fig. 8, B) and of 701 (well fed mother—Fig. 8, A) were still practically normal. These animals were now 7½ months old and well grown dogs. However, after three months more of these defective diets, when they were 10½ months old, there was a great difference between these two animals, which is obvious in the radiographs and photographs of these dogs (Fig. 8, C and D, and Fig. 9, E and F). It will be seen that 708 (Fig. 8, D, and Fig. 9, F) is very rachitic in appearance as compared with 701 (Fig. 8, C, and Fig. 9, E). The rachitic changes in 708 (Fig. 8, D, and Fig. 9, F) are comparable to those of late rickets seen occasionally in adolescents.

The greater resistance of 701 to the development of late rickets and the susceptibility of 708 to this disorder must have been due to the difference of the maternal feeding during pregnancy and lactation; for, since weaning at the age of 6 weeks, the diets of each and all the other conditions of life have been identical. It seems clear, then, that the influence of a defective diet given during pregnancy and lactation is not only evident in the offspring during early life, but that, even after a prolonged period of perfect feeding, the tendency to the development of defect is still obvious in the case of dogs whose mothers have a bad diet. It is surprising that the defective diet effect should be so lasting, and that it should be so difficult to overcome by a period of excellent treatment of the puppy.

Summary.

If bitches are fed during pregnancy on diets which, in the case of puppies, will lead to rickets, then the offspring have a greater tendency to develop this disease. This tendency in the young is not removed by a period of good diet, but may become evident again at a later period of defective feeding.

THE RELATION OF DIET TO SUSCEPTIBILITY TO INFECTIONS OF THE RESPIRATORY TRACT.

Attention has been drawn by many recent workers on dietetics to the increased susceptibility of animals to infection as the result of diets which, while good as regards their protein, fat, carbohydrate, and energy content, are defective in quality. McCarrison,⁸ for instance, has described the frequency of a catarrhal condition of the intestine, especially in the form of colitis, found in animals whose diet was deficient in vitamin B. In the course of my own work I commented on the readiness with which dogs succumb to distemper and the great intensity of mange when these diseases appear in animals whose diets are deficient in vitamin A.¹⁰ Drummond⁹ has described a lowering of resistance of adult rats to bacterial infection, manifesting itself sometimes in the form of an inflammatory

condition of the lungs, when they were fed on diets deficient in vitamin A. Cramer and Kingsbury²⁰ have also called attention to the mortality of rats from bronchopneumonia when these animals are kept sufficiently long on diets free from vitamin A. They consider that the atrophy of mucus-secreting cells in the mucous membrane of the trachea and larynx, observed by Mori,²¹ and in the intestine, observed by themselves, allows the local bacterial infection of these tissues when the diet is deficient in vitamin A. These are a few of the instances in which attention has been called to this important problem. Any information on the question of the relation of diet to resistance to infection, especially as it concerns the respiratory tract, seems to me to be of such great practical importance that I think it necessary to give my own experience on the subject.

At one period in the course of my experimental investigations on dogs, the work was greatly hampered by the development of an inflammatory condition of the lungs. Another condition of the lungs found *post mortem* in some of the dogs was that of local collapse, especially along the margins of the upper lobes of the lungs. This was often associated with patches of emphysema in other parts of the lungs. This condition, as a general rule, was not accompanied by congestion. It was usually found in dogs which, on account of their diet, had become either very lethargic or had developed muscular weakness or both.

Many of the experiments have been made with the object of elucidating the effect of diet on bone formation, so that the number of animals developing bone defect has been large. This, no doubt, accounts for the frequency with which muscular weakness and the accompanying condition of local lung collapse or atelectasis occur in these dogs.

Lately I have examined microscopically many of the lungs seen to be abnormal at the *post-mortem* examination made at the end of each experiment, and found the inflammatory conditions in all cases represented varying degrees of bronchopneumonia. It then seemed worth while to analyse the results and see in what way, if any, the incidence of the bronchopneumonia was related to the diet. I will briefly tabulate these results and then discuss them.

TABLE IV.—Lung Condition found at Post-mortem Examination of a Series of 330 Dogs in Relation to Diet.

Condition of Lungs.	Diets as regards Vitamin A Content.				
	Vegetable Fat, Vitamin A Deficient.	Butter + Vitamin A.	Butter, Vitamin A Destroyed by Heat.	Cod-liver Oil + Vitamin A.	Cod-liver Oil, Vitamin A Destroyed by Heat.
Normal	155	55	11	24	3
Broncho-pneumonia	43	0	4	0	1
Local collapse ...	23	9	2	0	0
Total	221	64	17	24	4

These results indicate a close relationship between the fat-soluble vitamin content of the diet and the susceptibility of the animal to develop an inflammatory condition of the lungs. All the cases of bronchopneumonia were found in dogs whose diets were deficient in fat-soluble vitamin, and no bronchopneumonia developed when the diet contained either butter or cod-liver oil. Except for the variable amount of fat-soluble vitamin, the diets of these animals would formerly have been considered good—that is to say, they contained an abundance of protein, fat, carbohydrate, and energy. In some cases the calcium intake was only sufficient on the assumption that the diet contained a large amount of calcifying vitamin. For instance, if diets of this nature contained cod-liver oil as the fat entity, and therefore an abundance of calcifying vitamin, the calcium intake was sufficiently high to result in perfectly formed teeth and bones. In fact, it is to be doubted whether any ordinary diet can be so low in calcium content as to lead to defective calcification of the body tissues if cod-liver oil is also ingested at the same time. On the other hand, when butter is the source of fat-soluble vitamin in the diet it is essential, in order to produce well formed teeth and

bones, strongly contracting muscles, and good general activity, that the diet should also be richer in calcium. The reason for this is probably that butter contains a much smaller amount of antirachitic vitamin than cod-liver oil, so that the butter effect on calcification is best seen when there is plenty of calcium in the diet. In the above table it will be seen that local collapse of lung tissue was found in nine cases in which butter was the fat eaten. If the calcium of the diets in these particular cases had been higher, the musculature of the animals would have been stronger, the animals would have been more vigorous, and no local collapse of lungs would have developed. Yet none of these animals eating butter, although some were abnormal in other ways, even as regards the lungs, developed bronchopneumonia. Although, therefore, it is certain that there is an intimate relation between fat-soluble vitamin in the diet and calcium, especially as regards the structure and function of bones, teeth, and muscle, it seems possible to deduce, on the basis of the above statistics, that this vitamin alone confers an increased power of resistance to lung infection even under conditions when bone and muscle structure is defective.

It is necessary, in discussing this question as to the relationship of diet and the resistance of the body to inflammatory conditions of the respiratory tract, to emphasize that, whatever truth there may be in the suggestion that fat-soluble vitamin aids in the defensive mechanism, it is only one point of a more complicated story. Whether there was any special organism which invaded the lungs of these dogs is not yet known, as, up to the present, the subject has not been studied in detail. There are certainly other points of crucial importance in the etiology of bronchopneumonia, but what these are cannot be stated definitely. In some cases, at least, the bronchopneumonia developed in animals which not only had the diet defect described above, but also had been taken out of their indoor kennels into the open air, where it was usually cold and windy and often wet, in order that their running powers should be determined. The opportunity, in fact, was presented to them of catching a "chill." The dogs on the diets containing vitamin A were also placed under the same conditions, but their resistance was apparently sufficient to make the low temperature of the external conditions of no account. It is impossible to state that this change of environment, which lasted only a few minutes, was always a factor in the development of the inflammatory condition of the respiratory tract, but it may have been a causative agent in many cases.

Another condition which commonly develops in puppies when feeding on diets containing excess of cereal and a deficiency of fat-soluble vitamin is diarrhoea. In animals which feed on such a diet for a long enough period diarrhoea generally develops, but this may only happen after severe defect of bone formation is present. On the other hand, diarrhoea may appear soon after the diet begins and before there is obvious bone deformity. It has seemed, although not proved, that the better the puppies are fed during the pre-experimental period, the longer time will elapse before the defective diets are accompanied by diarrhoea. This statement is definitely true of rickets both as regards the pre-natal and post-natal feeding of the mother, and it probably applies equally to the development of catarrhal conditions of the alimentary tract. It may also explain the variable susceptibility of young animals to catarrhal and inflammatory conditions of the respiratory tract.

THE POSSIBLE BEARING OF THE ABOVE RESULTS ON THE "CATARRHAL" CHILD.

The observations described above, dealing with the effect of feeding the maternal organism during pregnancy and lactation on the susceptibility of the young to develop rickets, together with the results showing the altered resistance under similar dietetic conditions to inflammation of the respiratory passage, have impressed upon me the possibility that the so-called "catarrhal" child is probably a product of defective feeding of the mother during pregnancy and lactation. There is general agreement among clinical workers that there is some common factor in the etiology of the diseases which result in the "catarrhal" child, the rachitic child, and the child with enlarged tonsils. So far as my own animal experi-

FIG. 1.—Photomicrograph of ground section of a perfectly formed human deciduous molar. Rarely found. (May Mellanby.)

FIG. 2.—Photomicrograph of human deciduous molar. Note defect in structure of dentine. A typical specimen as ordinarily found in this country. (May Mellanby.)

FIG. 3 (A, B, and C).—The effect of the calcifying vitamin. The jaws of three puppies of the same litter brought up on the same diets except that A contained 10 c.cm. of linseed oil daily, B contained 10 grams of butter daily, and C contained 10 c.cm. of cod-liver oil daily. Note the perfect formation of the teeth of C and the imperfectly formed teeth in A. (May Mellanby.)

FIG. 5 (A and B).—The effect of ultra-violet radiations. Photographs of the lower jaws of two puppies brought up on the same diet deficient in calcifying vitamin and living under the same conditions. Puppy A only was exposed thrice weekly for twenty minutes to the radiations of a mercury vapour lamp. Note the better formed teeth of A as compared with B. (May Mellanby.)

FIG. 4 (A, B, C, and D).—The effect of different cereals. Photomicrographs of ground sections of molar teeth of four puppies of the same litter. The diets of B, C, and D were deficient in antirachitic vitamin and were identical except that B contained oatmeal as cereal, C contained white flour as cereal, and D contained white flour and wheat germ (10 per cent.) as cereal. The diet of A was identical with that of B—that is, it contained oatmeal as cereal, but olive oil in Diet B was replaced by 10 c.cm. of cod-liver oil, which completely antagonized the bad effect of the oatmeal. Note how defective is the dentine in B (oatmeal), also that wheat germ has made the teeth of D worse than C (white flour). (May Mellanby.)

E. MELLANBY: DIET AND DISEASE.

MARCH 20, 1926]

FIG. 6 (A and B).—Radiographs of wrists of puppies (699 and 706) taken after ten weeks of the same experimental diet. A, during pregnancy and lactation the mother of 699 had been well fed—that is, received abundant antirachitic vitamin. B, during pregnancy and lactation the mother of 706 had been fed on defective diet—that is, deficient in antirachitic vitamin.

FIG. 7 (A and B).—Radiographs of wrists of puppies (703 and 707) taken after ten weeks of the same experimental diet. The mother of A (703) had been on a diet deficient in antirachitic vitamin during pregnancy and lactation, while the mother of B (707) had had a diet good in this and other respects during the same period.

FIG. 8 (A, B, C, and D).—Radiographs of wrists of two puppies (701 and 708). The mother of 701 (A and C) was well fed during pregnancy and lactation. The mother of 708 (B and D) during pregnancy and lactation had a diet deficient in antirachitic vitamin, and containing, among other things, oatmeal. After weaning the diets of 701 and 708 were always identical; they were well fed from 6 weeks to 6 months old; they were then put on the same rickets-producing diet. Radiographs A (701) and B (708) after six weeks of the defective diet; Radiographs C (701) and D (708) after eighteen weeks of the defective diet. See also Fig. 9, in text.

L. G. PARSONS: IRRADIATED CHOLESTEROL IN RICKETS.

FIG. 1.—Radiogram taken on admission to hospital, September 19th, 1925. The bones show very marked rachitic changes.

FIG. 2.—Radiogram taken November 11th, 1925, showing the result of treatment with irradiated cholesterol for a period of three weeks. A considerable degree of healing has occurred.

FIG. 3.—Radiogram taken January 6th, 1926. The bones have completely healed.

ments are concerned, I have got no evidence that enlarged tonsils of the type seen so commonly in children are produced by dietetic defect, but this may be because dogs do not develop the condition at all, or because I do not keep them long enough on bad diets. Clinically, however, it would probably be agreed that chronic catarrh of the respiratory passages of children, tendency to bronchopneumonia, rickets, attacks of diarrhoea, and, later, enlarged tonsils, are intimately related.

The catarrhal condition in children may develop at any time, but often it appears in the first few weeks of life and before post-natal conditions in themselves could be accounted responsible for the absence of all resistance to this type of infection. It seems to me that such cases can probably be explained on the basis of defective feeding of the mother during pregnancy, and the defects are probably of the type indicated by some of the experimental work on animals described in this lecture—namely, a deficiency in the diet of foods containing fat-soluble vitamin, such as milk, eggs, butter, cheese, animal and fish fat, and a

FIG. 2.—Photographs of two puppies—E (701) and F (703)—after eighteen weeks of defective diet. Animal 703 (half fed mother) has developed severe "adult rickets" as compared with 701 (well fed mother). For radiographs and details as to diet see Fig. 8 in special plate.

relative excess of cereals such as bread, oatmeal, and rice, and other foodstuffs deficient in vitamin A. The basis of this suggestion I have given above, and may be summarized as follows:

- (1) It has been shown experimentally that these defects in the maternal diet increase the tendency of the offspring to develop rickets.
- (2) The same defects in the diet seem, on the basis of the statistics supplied above, to increase the susceptibility of young animals to bronchopneumonia and inflammatory conditions of the respiratory tract, and, in general, to result in puppies of lowered vitality.
- (3) It is well known that the catarrhal child may develop this condition shortly after birth, and that it has a great tendency to become rachitic and to develop bronchopneumonia.
- (4) Puppies which develop rickets when feeding on these experimental diets frequently develop a catarrhal condition of the alimentary tract sooner or later, the time seeming to depend partly upon the kind of feeding of the mother and the puppy in the pre-experimental days.

Not only is there some experimental support for the suggestion, but experience shows that the dietetic defects described are those most commonly met with in human feeding. It is therefore probable that these defects of diet of women during pregnancy and lactation are responsible for some, and possibly much, of the illness and mortality of young infants. The new teachings of diet have been applied to some extent to the feeding of children, and this is no doubt partly responsible for the decrease in infant mortality during recent years, at a time when overcrowding and some other hygienic defects are as bad as, or even worse than, ever; but it is necessary to extend the teaching to the problem of maternal feeding. This would probably show its first effect by reducing the infant mortality of

children under 1 month of age, and, if the foregoing suggestions and experimental results are true, would result in great improvement in the physique of children. It would increase the resistance of infants to those infections which produce catarrhal conditions of the respiratory and alimentary tracts and all the other sequelae so generally recognized as likely to follow. It would certainly result in a better grown and less rickety type of child, and would do something also to improve the structure of the teeth and thereby to reduce the appalling amount of caries in the teeth of children. It would probably also bring about improvement in the general health of the pregnant woman, and do away with some of the unfortunate experiences to which she is liable.

THE VALUE OF IRRADIATED CHOLESTEROL IN THE TREATMENT OF RICKETS.

BY

LEONARD G. PARSONS, M.D.LOND., F.R.C.P.,

PHYSICIAN TO THE CHILDREN'S, GENERAL, AND INFANTS' HOSPITALS, BIRMINGHAM.

(With Special Plate.)

THE fact that many foods and vegetable oils which have no antirachitic value acquire that property after exposure to ultra-violet rays is now common knowledge. Hess and Weinstock¹ have recently shown that the antirachitic factor is confined to the unsaponifiable fraction of these substances, and that it resides largely in the cholesterol or phytosterol which they contain. During the year 1925 there appeared, almost simultaneously, three papers—one by the British workers Rosenheim and Webster,² in which they produced evidence that irradiation of cholesterol conferred antirachitic powers upon it; the others by two groups of American workers—one by Hess, Weinstock, and Helman,³ proving that irradiation of cholesterol and phytosterol rendered these compounds antirachitic, and the other by Steenbock and Daniels,⁴ showing that irradiated sterols possessed antirachitic properties.

Usually about half the unsaponifiable material from cod-liver oil consists of cholesterol, but Drummond and Coward⁵ have shown that this substance is not responsible for the physiological effects of the vitamins A and D. These results have recently been confirmed by Nelson and Steenbock.⁶ The cholesterol obtained from cod-liver oil, however, can be rendered antirachitic by irradiation.

The foregoing results were all obtained with laboratory animals, but Hess and Weinstock⁷ state that irradiated vegetables and dried milks possess curative value in the rickets of infants, and Cowell⁸ has demonstrated the value of irradiated whole milk.

Hess has given irradiated cholesterol to infants, but I do not know of any observations that have been published on the results obtained by its use in the treatment of infantile rickets.* I am indebted to Hess for the suggestion to use irradiated cholesterol clinically, and also for the method of irradiation. The cholesterol used was pure cholesterol prepared by the British Drug Houses, Ltd. A thin layer of this was placed in a Petri dish and irradiated by a

* Since this was written a paper by Hess and Weinstock has been published (*Lancet*, 1925, i, 12), in which they give the results of the treatment of three cases of rickets by irradiated cholesterol. In each case the inorganic phosphorus of the blood was increased and the radiogram showed slight healing.

quartz mercury vapour lamp (K.B.B. atmospheric type, 220 volts) for one hour at a distance of 1 foot. The irradiated cholesterol was then dissolved in linseed oil so as to make a 3 per cent. solution.

The case chosen for treatment was a child who had received cod-liver oil for a considerable period (five months) as an out-patient, but had shown little improvement. I have no data as to the antirachitic value of the cod-liver oil given, as this treatment was carried out at another hospital. The child was 3 years of age, had well marked bossing of the parietal and frontal bones, considerable enlargement of the epiphyses, antero-posterior bending of the tibiae, well marked Harrison's sulci, and showed florid rickets on radiographic examination. He was admitted into the Children's Hospital in September, 1925. For the first four weeks of his stay the child was given the ordinary hospital dietary, but received neither cod-liver oil nor cholesterol. Leonard Findlay holds that to draw conclusions as to the antirachitic effect of any treatment is fallacious unless such a probationary period of at least three weeks is allowed, because healing during this time may be the result of prior treatment.

Beginning with the fifth week, the child, although on the same diet, was given 3 per cent. irradiated cholesterol dissolved in linseed oil. For the first few days the dose was 1 drachm three times daily, and later 2 drachms three times a day. The results of this treatment were most striking, and are well shown in a series of radiograms of the wrist, for which I am indebted to my colleague Dr. C. G. Teall. All the radiograms taken before treatment was started showed severe rickets. During the first fortnight of the child's stay in hospital a slight degree of healing occurred, probably due to the administration of cod-liver oil before admission. The radiograms taken fourteen and twenty-eight days after his admission to hospital presented almost identical pictures, whereas that taken after treatment with irradiated cholesterol had been given for three weeks showed a most marked degree of healing. The radiogram taken on January 6th, 1926, showed that the rickets had completely healed.

It is important to note that cod-liver oil given throughout the late spring and summer months had failed to produce the cure which irradiated cholesterol produced during the autumn and winter months. Further evidence of the curative action of irradiated cholesterol is shown by the increase in the inorganic phosphorus and calcium of the blood. Before treatment the inorganic phosphorus was 4.67 mg. per 100 c.cm. of plasma, whereas after three weeks' treatment it had risen to 5.85 mg. per 100 c.cm., and in January, 1926, it had risen to the high figure of 6.8 per 100 c.cm. The blood calcium before treatment was 7.15 mg. per 100 c.cm. of serum, and in January, 1926, was 10.4 mg. per 100 c.cm.

Irradiated cholesterol when kept for some time loses its antirachitic power, and therefore it is advisable to irradiate a small quantity at a time. In the treatment of this case only sufficient cholesterol for one week's supply was irradiated at any one time. Hess and Weinstock⁷ found, however, that activated cholesterol dissolved in oil retains its potency much longer than if kept in the dry state or in a watery suspension. It is also of interest to note that these workers found that a 1 per cent. irradiated watery suspension of cholesterol, when injected subcutaneously, protected rats from rickets. One other point of importance in the activation of cholesterol is to avoid prolonged exposure to the ultra-violet rays, for this will render it inactive again.

Research is still being carried on by Drummond, Hess, Steenbock, and their co-workers as to the nature of the change induced in cholesterol by irradiation. That certain chemical changes occur has already been proved, but opinions appear to vary as to whether or not there is an actual photosynthesis of vitamin.

Drummond, Rosenheim, and Coward,⁸ in a paper published in March, 1925, state that irradiation of cholesterol produced vitamin A, the proof being that "administration of as little as 1 mg. of this material produced in most cases a prompt and marked resumption of growth in rats stunted by maintenance on a diet deficient in vitamin A," whereas control groups given 1 mg. of unexposed cholesterol

showed little or no response. Rosenheim and Webster² say in the paper to which reference has already been made that these authors have since found that the growth-promoting effect is not a lasting one, and they make the suggestion that the action of irradiated cholesterol on growth is apparently identical with that of ultra-violet light, and appears to consist in mobilizing the animal's reserves of vitamin A. Nelson and Steenbock⁶ have, however, put forward quite a different explanation, and suggest that vitamin A is not produced by irradiation of cholesterol, but that the growth-promoting effect produced is due to the conferring of antirachitic powers on it. These authors believe that all vitamins are necessary for growth, and that there is no particular reason for speaking of any one of them as "the growth vitamin." They are convinced that when a rat does not grow for some weeks, in spite of an absence of ophthalmia or respiratory trouble, and in spite of the fact that it is provided with an abundance of vitamin B, good protein, salts, and calories, failure in growth is then due to the antirachitic factor. Irradiation of such a rat will promptly reinstate growth, and with this treatment the content of the tissue of the rat in antirachitic factor is increased, but additional amounts of vitamin A will not elicit such a reaction. These authors would therefore seem to regard xerophthalmia, and not lack of growth, as the proof of vitamin A deficiency, and their views have received support from some recently published observations by Rosenheim and Drummond.¹⁰ The latter workers have elaborated a delicate colour reaction for vitamin A, and they found that cholesterol did not give this colour reaction, although they still hold the view that vitamin A is the true growth-promoting vitamin.

It is quite easy to dissolve additional cholesterol in cod-liver oil, and I am now treating a child who is suffering from rickets with irradiated cholesterol dissolved in cod-liver oil. If irradiation synthesizes the antirachitic factor (vitamin D) this should prove a method of enriching the vitamin content of the oil. If, on the other hand, the action of irradiated cholesterol is to mobilize the child's supply of vitamin, it should ensure greater use of the vitamin already present in the oil. Linseed oil is not the most palatable vehicle, and in future I propose to try some other form of solvent. Colza oil has a much less objectionable taste, and cholesterol is, apparently, more easily soluble in it than in linseed oil. Cholesterol also dissolves easily in warm liquid paraffin, but crystallizes out of solution at room temperature, although, according to Rosenheim and Webster, after irradiation it remains more or less in solution, and they used for experimental purposes a 2.5 per cent. solution in paraffin.

These laboratory experiments to which I have referred are of the greatest possible clinical interest, and it is of particular importance to determine whether or not the view that vitamin A is the "growth vitamin" is correct. For instance, in coeliac disease there is marked stunting of growth, which in all probability is due to a diminished absorption of fat-soluble vitamins, consequent upon the inability of children suffering from this disease to absorb fat. Certain cases also show definite clinical and radiographic evidence of rickets, and I have been able to observe healing of the rickets when such cases have been treated by ultra-violet rays. Coeliac disease certainly does furnish some clinical evidence in favour of Nelson and Steenbock's views, for although stunting of growth, rickets, tetany, and scurvy may occur in the course of this malady, I have never seen xerophthalmia develop, nor do I know of any record in the literature of its occurrence. At the present time I am treating two cases of this rachitic type with irradiated cholesterol dissolved in paraffin, and one of them is also receiving treatment by ultra-violet rays. I have chosen paraffin as the vehicle because it is not normally absorbed from the intestine, and therefore should not interfere with the free fat dietary which is essential for the treatment of this disease. If the lack of growth is due to non-absorption of the antirachitic factor, as suggested by Nelson and Steenbock, absorption of irradiated cholesterol should stimulate growth. If, on the other hand, Drummond's contention that vitamin A is thus synthesized, and that vitamin A is the growth vitamin, is correct, then growth should also be stimulated.

Conclusion.

A case of severe rickets is described which has been under treatment during the greater part of the year 1925. From April to the beginning of September the child received cod-liver oil as an out-patient, but with only slight improvement; during the last three months of the year he was admitted into hospital and irradiated cholesterol was administered, with the result that the rickets was cured.

Whilst it is clearly impossible to generalize from one case, the results obtained suggest that this method of treatment is well worth a trial, either alone or in combination with cod-liver oil, in cases which do not respond quickly to cod-liver oil. It is not an expensive method of treatment; the amount of cholesterol used weekly represents a cost of about 2s. 6d.

THE ETIOLOGY OF GASTRIC AND DUODENAL ULCERATION.*

BY

K. W. MONSARRAT, M.B., C.M., F.R.C.S. EDIN.,
 LECTURER ON OPERATIVE SURGERY, UNIVERSITY OF LIVERPOOL.

THE etiology of chronic gastric and duodenal ulceration is one of the most actively debated pathological problems to-day. A great deal of experimental and clinical research is being done on the subject, but there are many unsettled questions. Among the most important are these: What is the role, if any, of infection? What is the actual part played by the gastric secretion? Is it the prime and sufficient cause of chronic ulceration? If not, what antecedent morbid conditions contribute to the appearance of ulcer? What, if any, is the part played by the nervous system?

INFECTION.

Important in its bearing on the possible part played by infection in the causation of gastric ulcer is the work of Bolton.¹ He employed a serum produced by repeated injections of the gastric cells of one animal into another. In the presence of gastric juice injection of this serum resulted in the appearance of gastric ulceration. If the gastric juice was put out of action by sodium bicarbonate ulceration failed to appear. The serum, therefore, did not produce necrosis, but rendered the gastric cells susceptible to attack by the gastric juice. He considered that other blood-circulating poisons could prepare the way for self-digestion, and that the frequency of gastric ulceration in general intoxication was due to attack by the gastric juice when the resistance of the gastric cells was lowered. It did not appear from his researches that hyperacidity alone was able to produce ulceration, but he found that if a series of animals were injected with serum, and hyperacidity produced in some and not in others, then those with hyperacidity showed much more marked gastric lesions than those without. He further showed that if, in the cat, delay in gastric emptying was produced by putting the animal on a meat diet, the formation of ulcer was more rapid than when the animal was on milk and there was no delay. When there was a definite delay in the emptying time of the stomach, then there was a definite delay in the healing of experimental ulcers.

Bolton's work bears, therefore, on the subject from two directions—first, on the possible influence of intoxications, specific or general, in preparing the ground for auto-digestion; and secondly, on the role played by the gastric secretions. He found that the injection of toxins other than

gastrotoxin—for example, hepatotoxin, enterotoxin, prepared in a similar manner—led to the formation of gastric ulceration.

Reeves² drew attention to certain local circulatory peculiarities of the stomach and duodenum which appeared to predispose to stasis and thrombosis. He stated that along the lesser curvature of the stomach the circulation is carried on through parallel arterioles supplied at both ends by arterial majors, and this condition, he considered, gave an opportunity for some stasis. Further, that a triangular supply throughout the first two inches of the duodenum predisposed to thrombosis. He had in mind that this tendency to stasis and thrombosis might be made actual by infective processes.

As long ago as 1907 Türk³ stated that he had produced peptic ulcers of the stomach and duodenum of dogs in 100 per cent. by feeding the animals on bouillon cultures of *B. coli communis*. On cessation of the feeding the ulcers were found in varying stages of healing. These ulcers for the most part caused the death of the animals from perforation and haemorrhage.⁴ Türk's experiments have not, so far as I know, been repeated and confirmed.

Dawson⁵ in 1912 accepted the proposition that the primary causes of gastric ulceration were toxic and bacterial agencies which acted directly on the gastric cells. He considered that these produced in the first place what he called the mucous ulcer, and that the chronic ulcer was a further development from this. He stated that in a series of personal observations he had found the stomach sterile in cases of chronic ulcer; fourteen such cases were examined bacteriologically, and ten showed sterility.

The work of Rosenow requires examination in some detail. In a paper published in 1913⁶ he stated that ulcer of the stomach or duodenum, or both, was produced by intravenous injection of streptococci in eighteen rabbits, six dogs, and one monkey. In most of the rabbits and "some" of the dogs there was also arthritis, in some myositis and the "picture of an ascending nephritis." Ulcers occurred when streptococci of a middle-grade of virulence were injected. These streptococci were derived from cases of rheumatism. Areas of haemorrhage were found in the mucous membrane within twenty-four hours of injection, and ulceration in forty-eight hours. Some of these ulcers became chronic, but no details as to persistence are given in the paper. In 1916⁷ he reported the experimental production of ulceration and haemorrhage (the percentage of ulcer incidence is not stated) in 60 per cent. of 103 animals injected with eighteen strains of streptococcus derived from human gastric ulcers. The ulcerations were often single and deep, and showed a marked tendency to perforation.

In 1921⁸ he published a further series of observations. Sixty-five animals were injected with streptococci derived from patients suffering from ulcer of the stomach or duodenum. Thirty-two of these were injected with cultures from the tonsils, six with organisms in the pus from the tonsils, seven with streptococci from three excised ulcers, and twenty-three with cultures from infected teeth. The incidence of lesions (that is, ulceration or haemorrhage) was about equally high in each group—that is to say, 80 per cent. The numbers in which actual ulceration developed is again not given. The animals were killed two to three days after the last injection. From actual human ulcers thirty-seven strains of streptococcus were isolated and injected into 168 animals; of these, 68 (45 per cent.) showed "lesions" in the stomach and duodenum; the type of lesion is not stated, nor the comparative frequency of gastric compared with duodenal lesions. Rosenow published a further paper in 1923⁹ giving a parallel series of observations in the hog, cow, sheep, calf, and dog. He stated that streptococci were isolated in pure culture or in predominance from a series of gastric ulcers in these animals. Ulcer, or haemorrhage, or infiltration of the stomach was produced in 86 per cent. of rabbits and dogs injected with freshly isolated cultures. Similar results were obtained with cultures of streptococcus from infected tonsils in the cow and the dog which had ulcer. Rosenow maintained that results such as these had not been obtained with streptococci of similar morphology from sources other than ulcer.

* A paper read before the Pathological Section, Liverpool Medical Institution.

There is so far no confirmation of Rosenow's experimental results. Wilkie has stated that he had been unable to confirm them in certain respects, but I am not aware that he has published any personal investigation. Their bearing on the etiology of the chronic ulcer of the stomach and the chronic ulcer of the duodenum in man is not clear. He appears to have shown two things: that streptococci can be isolated from the majority of chronic gastric and duodenal ulcers; and that streptococci from these sources, and also from many other sources, produce in a large percentage of animals when intravenously injected certain acute lesions in the gastric mucous membrane, sometimes without obvious lesions elsewhere. There is a want of detail in the published experimental results which makes it difficult to judge their significance. Durante (a colleague of Rosenow in the Mayo Clinic) says: "If the results obtained in experimental work do not exclude the possibility of ulcers forming in consequence of bacterial infection, the fact remains none the less that bacteria are found in a limited number of cases only." He appears to incline to the view, in the face of Rosenow's work, that the presence of organisms is the result rather than the cause of ulceration.

Gibson in 1921 described the lesions produced in a monkey by injection of a streptothrix obtained from a case of acholuric jaundice. These included an inflammation of the spleen with thrombo-phlebitis giving rise to infective emboli which in the stomach resulted in ulceration, there being several circular ulcers with sharply defined edges not confined to any area. This, no doubt, was an example of gastric lesions produced by retrograde venous thrombosis, a condition known to surgeons and recognized as the explanation of some cases of gastric haemorrhage in certain abdominal infections.

In supplement to the experimental investigations above noted there is a general clinical view that gastric disorder, chronic gastritis, and also gastric ulcer, are frequently associated with infections elsewhere—dental, nasal, tonsillar, and in the gall bladder and appendix. At any rate it is a clinical experience that must be noted that gastric pain, and also the other signs and symptoms which are usually associated with ulcer, are often ameliorated and not infrequently disappear after the elimination of infection in one or other of these situations.

Rosenow has drawn the conclusion from his work that ulcer—that is, chronic gastric ulcer and chronic duodenal ulcer found in the human subject—is a lesion produced by a specific streptococcus which attacks the gastric wall, reaching it by way of the blood stream, and that this streptococcus is the effectual cause of the disease. Bolton, on the other hand, had an equal experimental success with a variety of toxin inoculations, and considered that attack by the gastric juice was an essential part of the process of ulcer production.

ALTERATIONS IN SECRETION.

That auto-digestion plays a part in ulcer is a view which dates from before John Hunter, who explained the fact that man did not invariably digest his own stomach wall on the ground that the gastric juice could not attack living tissue. Various writers have ascribed ulcer formation to alterations in the chemistry of the gastric secretion, more particularly to hyperacidity and hyperchlorhydria. Until the method of the fractional test meal examination was introduced hyperchlorhydria was credited by many with the chief role in the production of the chronic ulcer. Investigations by this method have led to the abandonment of this view.

According to Moynihan⁹ hyperchlorhydria was demonstrated in 72.7 per cent. of a series of 71 cases of duodenal ulcer; and in 20 per cent. only of a series of 39 cases of gastric ulcer. These figures are approximately the same as those of other investigators. The combined figures of Bell and Hunter, as given by Ryle,¹⁰ are:

<i>In gastric ulcer:</i>			
Normal acidity	57 per cent.
Hyperchlorhydria	33 "
Achlorhydria	10 "
<i>In duodenal ulcer:</i>			
Hyperchlorhydria	70 per cent.
Normal acidity	30 "
Achlorhydria	0 "

In duodenal ulcer in particular the fasting juice shows a high acid curve up to 80 and 100 c.cm., compared with a normal of 20 c.cm.

Busterman¹¹ recorded the findings in two series of gastro-jejunal ulcers. In one series of 47 cases hyperacidity was present in 60 per cent., in a second series of 36 hyperacidity was present in 73 per cent.

It is not necessary to review the numerous observations on the gastric secretions in ulceration which have been recorded by workers using the fractional test meal method. It is generally agreed that in duodenal ulcer the acidity of the resting juice is usually high and that there is generally a climbing curve, after the initial fall which follows the meal, up to about the end of the second hour, and that in the absence of stenosis the curve then usually falls, to rise later to the high fasting level. Further, that in pyloric stenosis there is a climbing acidity curve which usually rises steadily during the third hour and often later. Thirdly, that in gastric ulcer without stenosis there is no acidity curve that can be called characteristic. The figures given by Ryle show, in fact, that the percentage of hyperchlorhydria curves in gastric ulcer cases may not reach the percentage in 100 normal individuals.¹²

	Hyperchlorhydria.	Normal.	Hypo-chlorhydria.
Duodenal ulcer (50) ...	68	23	9
Gastric ulcer (16) ...	13	75	12
Normal (100) ...	15	80	5

I do not know that the proposition has ever been put forward that hyperacidity and a presumed consequent hyperactivity is solely responsible for the initiation and development of gastric and duodenal ulcers. At any rate it is perfectly clear that such a proposition has no basis to rest on, for the following sufficient reasons:

First (I quote Carlson as the authority here). Normal gastric juice is equal in total acidity to the maximum acidity reported by clinical observers for so-called hyperacidity in man. He says: "So far as I am acquainted with the literature there is no evidence that the gastric glands under any pathological conditions are able to or do secrete a juice of higher than normal acidity. Moreover, the presence in the stomach of gastric juice of full acid strength leads by itself and immediately to no untoward results."¹³

Secondly. It has been pointed out by Boldyreff and others that the acidity curve is not a secretory curve, and that its variations depend in the main on the presence or failure of that process of neutralization by regurgitation which appears to have as its object the production of an optimum digestive activity varying with the stages of digestion.¹⁴

Thirdly. The examination of normal individuals has shown that curves varying from high acidity through normal and down to complete anacidity are recorded without any corresponding variations from apparent health. Carlson says:¹⁵ "There is no disease known capable of inducing true gastric hyperacidity, the pathological variations in acid and pepsin concentrations are invariably in the direction of a decrease." Actual hyperacidity in the sense of a gastric juice of greater than normal acidity has not been demonstrated in any disease and probably does not exist; actual hypersecretion does, however, of course occur.

There is, therefore, at present no evidence that a high acidity of the gastric juice is a primary factor in the causation of ulcers, gastric or duodenal. We must not, however, lose sight of the remarkable difference between the average duodenal ulcer acid curve and the average gastric ulcer acid curve; in the explanation of this difference there may be a clue to ulcer formation. The work of Boldyreff and Carlson brings us definitely to the conclusion that the climbing curve of duodenal ulcer and of pyloric stenosis is due in both instances to a failure in neutralization by regurgitation, and this leads up to the study of stomach motility and its disturbances.

DISTURBANCES OF TONUS AND RHYTHM.

Rogers and Hardt,¹⁶ studying the stomach movements by the rubber balloon and x ray, and comparing their results with the contributions of Cannon, Carlson, and Forsell,

conclude that the normal stomach exhibits the following types of muscular activity:

1. A tonic grasp of the upper stomach musculature upon the food. This tonic condition exhibits slow rhythmical variations.
2. Peristaltic contractions of the antrum pylori.
3. Peristaltic contractions (hunger contractions) of the entire stomach.

During normal digestion the peristaltic waves sweep over the lower part of the stomach. In the meantime there are slow rhythmical tonus variations of the upper part of the stomach. As the stomach empties itself the peristaltic waves arise from points higher and higher toward the cardiac end, run over the entire stomach, and culminate in more or less tetanic contractions of the antrum. Both tonus rhythm and peristalsis may be inhibited by introducing food or liquid into the stomach.

Carlson, Orr, and McGrath, studying the hunger contractions of the Pavlov pouch, conclude that these contractions are controlled by a gastric automatism and not by motor impulses through the vagus. It has, however, been demonstrated that section of the splanchnic nerves increases gastric tonus and augments hunger contractions.

What are the variations from normal gastric motility which occur in disease?

It is, I presume, agreed that gastric pain is the pain of gastric muscular spasm or tetanic contraction, and that it is frequently present in the absence of any ulcer lesion in either stomach or duodenum. It is the tetanic contractions of the hunger period which wake the infant; the infant does not cry because he thinks of food, but because his gastric musculature is causing him a discomfort. As in the case of the small intestine, where, contents of a certain kind set up the painful contractions of colic, which contractions cease on expulsion of the said irritating contents, so also in the stomach contents of certain kinds may set up abnormal contractions which may be felt as discomfort or pain. It seems probable also that psychic influences (as shown by Rogers and Hardt) are capable of interfering with the normal course of gastric rhythm. There is less actual clinical evidence that intoxications are capable of interfering in the same way, but nicotine at any rate does so, and it may be the case also in bacterial intoxications. Further, there is much clinical evidence that visceral disease elsewhere—in the gall bladder and appendix in particular—may be associated with abnormalities in the gastric muscular mechanisms. Among actual observations we have the figures given by Ryle showing hypertonus to be nearly twice as common in cases of appendicitis and cholecystitis as in the normal individual.

In putting forward a thesis that alterations in gastric rhythm, produced by one cause or another, are themselves the primary disorders in the process which ends in chronic ulcer, I propose to consider the duodenal ulcer first.

Duodenal Ulcer.

Clinical and radiological observations show that in individuals with actual duodenal ulcer there are the following variations from normal gastric motility:

1. A marked early hypertonus leading to an exceptionally early evacuation.
2. A relaxation of the pylorus.
3. A late exaggeration of hunger contractions which are sensible as pain—that is to say, a late spasm of pars pylorica and pylorus which is often shown radiographically by an unduly long retention of the last portion of the opaque-meal.

Hurst has shown that this composite picture may be regarded as an extreme exaggeration, a vicious exaggeration of a rhythm type commonest in the male, which shows in radiograph the steer-horn stomach outline, in contrast with the J-shaped stomach, commonest in the female.

Certain characteristic alterations in the chemistry of the gastric contents are the consequence of, not the cause of, these alterations in gastric rhythm. As far as the chemistry of the stomach is concerned, in a typical case the gastric juice after the first quarter of an hour shows an increasing acidity owing to absence of neutralization from the duodenum; the failure in regurgitation is no doubt due

to the increased tonus on the gastric side of the pylorus, sufficient to prevent any reflux of duodenal secretions into the stomach. As far as the duodenum is concerned, the effect of the morbid rhythm is the early forcible discharge into this segment of gut of an unneutralized gastric juice.

The effect of unneutralized gastric juice on the wall of the duodenum has been studied experimentally. The most important experimental study is that of Mann.¹⁷ He describes the production of peptic ulcer in the dog by the following method. The pylorus was cut and the distal end closed. The first portion of the jejunum was cut and the distal part anastomosed to the pylorus. The proximal jejunal end was then anastomosed to the ileum. In this way the stomach is made to empty itself into the jejunum and the duodenal secretions into the ileum at least 50 cm. from the pylorus. Following the operation a typical chronic peptic ulcer developed in 90 per cent. of the dogs. Mann satisfied himself that operative trauma was not responsible for the ulcers. They did not begin to heal until after the anastomosis had healed; they did not involve the suture line primarily. In certain other experiments the duodenal secretions were carried to the jejunal loop close to the pyloric anastomosis; ulcer did not form under these conditions. When, however, in the same animals, the duodenal secretions were led away to the lower ileum ulcers developed at the usual site and in the usual time. In these cases the site of the anastomosis was untouched at the second operation and the ulcers could not therefore be ascribed to operative trauma. The same type of ulcer lesion was produced in the duodenum following transplantation of the common bile duct and the pancreatic duct into the terminal ileum. None of the ulcers healed spontaneously, but if the duodenum was reanastomosed to the jejunum close to the pylorus the ulcers healed, and this also occurred when the ulcer area was protected from the impingement of the gastric contents. Mann interprets his results as follows: (1) The operative procedure of draining the alkaline secretions of the duodenum away from the area of emergence of the gastric contents exposes the jejunal mucosa to an acid medium longer than normal. (2) The ulcer develops where the gastric contents primarily impinge on the jejunal wall. He thinks, however, that there must be some underlying primary change in the mucosa, such as infection, though why he thinks so he does not say.

Another less elaborate series of experiments was reported by Brancati.¹⁸ He states that peptic ulcer developed in five out of ten dogs after resection of the pylorus and the pyloric part of the stomach. His experiments appeared to demonstrate that peptic ulcers follow removal of the pyloric part of the stomach and consequent early flooding of the duodenum with gastric secretions.

These experiments lend strong support to the view that, in duodenal ulcer at any rate, the gastric juice, when discharged rapidly into the first part of the duodenum and unneutralized by the duodenal secretions, is capable of initiating and developing ulceration, the ulcer forming where from impact the damage of the mucous membrane is maximal. In support of this view is the fact that surgeons are acquainted with a class of case in which all the symptoms of duodenal ulcer are present along with characteristic radiographic and test meal findings, which prove on operation to be examples not of developed ulcer but of a duodenitis, the wall of the gut showing hyperaemia and organized lymph on the serous coat without actual underlying ulceration.

It is also true that in almost all cases of actual duodenal ulcer there is also duodenitis; it is a common experience to find an ulcer on the posterior wall associated with definite signs of inflammatory reaction on the anterior wall, the serous coat being covered with a vascular organized lymph coating. In other cases, again, there is widespread duodenitis without ulcer. Recently I operated upon a case presenting a complete clinical picture of duodenal ulceration with corresponding radiographic findings and fractional test meal result. I found no ulcer, but the whole of the duodenum was hyperaemic and the first part was overlaid with a vascular lymph coating; the hyperaemic blush extended to the first part of the jejunum. Further, I was able to demonstrate a remarkably patulous pylorus; without any difficulty three fingers were invaginated

through it from the duodenal side into the stomach. With such a condition, given a stomach of high tonus, the gastric contents will early flood the duodenum.

The counterpart of this condition is the "blushing" stomach wall which is commonly associated with pyloric spasm and unduly long retention of gastric contents. This condition I have often observed, in the absence of ulceration, in cases of pyloric spasm and gastric delay associated with such conditions as chronic cholecystitis. The blush may be a vasomotor phenomenon, but I look upon it as probably caused by the irritation of retained gastric secretions; in cases of pyloric spasm it is most marked in the antrum pylori. Recently I operated upon a case of chronic cholecystitis, the chief symptom being recurring attacks of violent vomiting; the radiograph showed a considerable six-hour remainder; the fractional test meal showed a rapidly climbing acid level after the first hour; the pylorus was a tight ring with a lumen of pencil size, and over the antrum pylori was an intense blush sharply defined at the pylorus. Whether this blush is in fact a reaction to irritation, whether it is indicative of a gastritis, cannot, perhaps, be definitely stated, but this is, I think, the view generally held by surgeons.

Gastric Ulcer.

In considering whether this view of ulcer formation will explain the gastric ulcer, reference must be made to the views of Barclay.¹⁹ He remarks that septic conditions in the mouth and from other sources, constipation, mucous colitis, and a variety of other conditions are capable of producing spasmodic contractions of various parts of the stomach. The spasm may be so severe that it produces a narrowing of the lumen which from time to time is of great functional importance, causing a definite obstruction to the passage of food. By some indiscretion of diet or want of mastication something too large to pass easily through the channel has to be forced through by peristalsis. This produces bruising or possibly an abrasion at the point where the lumen is narrowed and where there is constant irritation of food passing over it. It is probable also that the spasm interferes with the blood supply. A surface is exposed that is not structurally fitted to withstand the action of the gastric juice; in this way an ulcer is formed which perpetuates the original spasm that determined the site of the ulcer. Barclay stated that spasmodic hour-glass contraction of the stomach is quite common without ulcer; also that in fully half of the cases of stomach ulcer there is pyloric obstruction. It is not, perhaps, possible to accept the idea of direct mechanical injury by stomach contents, but the suggestion that the primary morbid condition is abnormal gastric spasmodic contractions is noteworthy as the opinion of an experienced radiologist.

Gastric ulcer occurs characteristically in the hypotonic J-shaped stomach. In this type the common alteration from the normal in motility is the appearance, at an early stage of digestion, of exaggerated peristalsis and contractions of the circular fibres of the pyloric region and antrum pylori. When this condition of exaggerated peristalsis is marked we have a type of "dyspepsia" in which early pain is the chief symptom. In ulcer of the lesser curvature the most constant abnormal muscular phenomenon is a spasmodic constriction about the mid-stomach; in ulcer about the pylorus the most constant muscular abnormality is spasmodic contraction of the pylorus itself.

In these spasmodic contractions, occurring in different situations, it is easy to see how the effect of impact in damaging mucous membrane, causing a local gastritis and eventual ulcer, may come into play. In persistent spasm of the stomach body the greater curvature is always drawn up to the fixed lesser curvature by the circular muscle fibres; under these conditions discharging gastric contents will impinge on the lesser curvature and may damage the mucous membrane sufficiently to pave the way for digestion by the gastric juice. The objection that the spasmodic contraction or incisura is the consequence and not the cause of ulcer formation cannot be maintained; radiographers and surgeons are agreed that a fixed spasm of the circular fibres, particularly at the pylorus or at the junction of the fundus and the antrum pylori, is a common finding in cases suspected of ulcer on account of gastric pain, but

proved to be cases of gastric disorder from other causes. In such cases the point of impact of the gastric contents when the stomach contracts will be the lesser curvature near the pylorus or in the antrum pylori, and in these situations, of course, ulcer is most common.

The type of stomach in which gastric ulcer is most common has certain functional peculiarities. This stomach is usually hypotonic so far as peristaltic movements are concerned, but it exhibits an early pyloric spasm, which is clinically shown by early pain and radiographically by delayed emptying—that is to say, the stomach wall is subjected for an unduly long period to the presence of unneutralized gastric secretion. Its characteristics are the exact counterpart of those of the stomach in which duodenal ulcer tends to occur. They may be tabulated as follows:

<i>In duodenal ulcer:</i>	<i>In gastric ulcer:</i>
Hypertonus.	Hypotonus.
Patulous pylorus.	Spasm of pylorus or pars media.
Rapid emptying.	Slow emptying.

In the first case the result of the gastric functional disorder is that the duodenum is early flooded with unneutralized gastric secretions. In the second case the result is a retention of the stomach secretions, unneutralized, in the stomach itself. Bolton found that when there was a definite delay in the emptying of the stomach there was a definite delay in the healing of experimental ulcers. In either case it seems inevitable to conclude that the gastric juice plays a very definite role. That it does so is not only strongly supported by the experimental evidence of Bolton and of Mann, but also by the clinical experience of jejunal ulceration after gastro-enterostomy. Ryle has pointed out that it is particularly in the case of the sthenic or hypertonic stomach that jejunal ulcer is liable to occur, and the explanation appears to be that the ulceration develops in consequence of the flooding of the jejunum by gastric secretions at so early a stage that the alkaline duodenal secretion has not fully developed. The influence of impact* in determining the site of the ulceration is also well illustrated; jejunal ulcers develop either at the edge of the anastomotic ring or on the jejunal wall opposite to the anastomosis.

TROPHIC INFLUENCES.

If it be true that morbid alterations in gastric rhythm play the role in the production of gastric and duodenal ulceration that is suggested, it seems likely that these motor disturbances are associated with some trophic changes, and that such trophic changes may also assist in paving the way to ulcer formation. The work of Durante is interesting in this relation.

Durante²⁰ produced gastric ulceration in dogs by resection or ligation of the median splanchnic nerve. Two types of lesion occurred—a haemorrhagic lesion and a necrotic lesion. The haemorrhagic lesions healed, but the necrotic lesions were traced to ulceration which tended to become chronic. He ascribed these lesions to the action of adrenaline produced in excess by the operative stimulation of the sympathetic. He says: "ulcer may be produced by any agent capable of damaging the sympathetic nervous system, as it is on the integrity of this system, which controls circulation, secretion, and profound sensibility in the stomach, that the very life of the gastric cell may be said to depend."

The ulcers produced by Durante's operative procedure on the sympathetic appear to have been definite chronic ulcers resembling anatomically the chronic ulcer in the human subject.

SUMMARY.

The conclusions to be drawn from this review are as follows:

1. There is no satisfactory evidence that chronic gastric and duodenal ulceration is primarily due to direct invasion of the stomach or duodenal wall by specific organisms.
2. Chronic gastric and duodenal ulceration is not caused by alterations in the chemistry of the gastric secretions.
3. The evidence available points to alteration in gastric rhythm being the primary morbid condition, which when persistent leads to the development of ulceration.

* Professor Glenn has suggested "wear and tear" as an alternative to "impact." It is certainly a better descriptive term.

4. The site of the ulceration is the site of maximum wear and tear by gastric contents whose normal neutralization has been interfered with by the altered gastric rhythm.

5. The gastric secretions, innocuous to the stomach wall under normal conditions, cause irritation and eventual ulceration, when the gastric rhythm is altered; trophic changes may also prepare the way for this action.

6. The fundamental condition on which these morbid changes in gastric motility and rhythm depend is doubtless a disorder of gastric innervation, which may have its origin in toxic influences, or psychic influences, or in reflex influences from disease elsewhere. The innervation of the stomach is not, however, so completely analysed as to make it possible to say whether these influences bear on an autonomic gastric system or whether they affect the stomach by way of the vagus or sympathetic. There is, however, some evidence that in the gastric type, which is usually associated with duodenal ulceration, there is some inhibition of impulses by the splanchnic path, and that in the gastro type, which is usually associated with gastric ulceration, it is the vagus impulse which is depressed.

THE SURGICAL TREATMENT OF DANGLE-FOOT.*

BY

ROBERT OLLERENSHAW, M.D., F.R.C.S.,
ORTHOPAEDIC SURGEON TO THE ROYAL MANCHESTER CHILDREN'S
HOSPITAL AND TO SALFORD ROYAL HOSPITAL.

In dealing surgically with the residual paralysis of anterior poliomyelitis our endeavour must be to utilize to its best possible advantage the power which remains to us and to make the limb as efficient as possible.

In the leg, where weight has to be borne, we must attempt to provide stability and independence of extraneous supports. In drop-foot many operative procedures have attempted to suspend the foot by slings of silk, tendon fixations, and fascial bands, but the results have on the whole been disappointing, as the constant drag of the pendulous foot in time produces elongation of the artificial ligaments. Many such cases seem to be brilliant successes for a few months, but, seen a year or two later, have to be written off as ineffective.

The commission appointed by the American Orthopedic Association, which inquired into the stabilizing operations on the foot, reported that as regards drop-foot "none of the standard operative measures considered can be recommended as a standard procedure."

Two years ago I began to try a method devised by W. C. Campbell of Memphis, U.S.A., by which the interference with the drop-foot was not provided on the anterior aspect of the ankle in the form of a sling, but at the back of the joint by a "bone stop." In a large percentage of paralytic feet it is necessary to remove bone to correct deformity or to stabilize the mid-tarsal region and subastragaloid joint. The bone thus removed is utilized to build up a bone stop at the back of the ankle.

The usual incision for astragalectomy, and for most stabilizing operations, is used, commencing one inch above the ankle, internal to and parallel with the fibula, and passing down towards the external cuneiform. The deep fascia is divided; the extensor tendons are retracted inwards. The ligaments and periosteum are cut down to bone and the mid-tarsus exposed. The rounded articular surface of the head of the astragalus is removed by osteotomy. A large part, or the whole, of the scaphoid is removed. I have performed this operation at the age of 8 years and upwards, and find that in younger subjects it is better to remove the whole scaphoid. The

* Read before the meeting of the British Orthopaedic Association in October, 1925, when the operation was demonstrated and a series of results shown at the Royal Manchester Children's Hospital.

articular cartilage is now removed from the os calcis and cuboid with enough underlying bone to permit of good apposition of the mid-tarsus. The are next opened and the articular

FIG. 1.—A lateral radiographic view of a foot a week after operation; the scaphoid, with its superimposed fragments, can be clearly identified.

FIG. 2.—Shows the foot three months after operation, when the fusion of the various elements is seen to be complete.

excised. In exposing these joints the pad of fat and connective tissue lying in the subastragaloid fossa should not be removed, but merely turned aside and later replaced so as to leave no "dead space." The removed portions of bone and cartilage are placed in saline, and, while the anterior incision is being closed, an assistant cuts away all cartilage and prepares the bony pieces for the construction of the "stop" behind the joint.

The posterior incision is now made about six inches long directly over the tendo Achillis. The tendon is cleared and divided as for a Z-lengthening operation. The proximal and distal ends are turned up and down. The loose tissue lying between the tendo Achillis and the back of the tibia is now incised in a vertical direction and the back of the tibia and the upper surface of the os calcis exposed. A notch is cut in the os calcis large enough to receive the broader end of the trimmed scaphoid. This is placed in position and tapped down so as to get a hold. The smaller pieces of bone are now grouped together above the upper end of the scaphoid and the suturing of the tendo Achillis holds them nicely in place. The required amount of lengthening of the tendon is made so as to allow a right-angled position of the ankle. The skin is closed and a light plaster cast applied for six weeks. At the end of this time a brace is fitted so as to prevent any movement in the direction of plantar flexion for six months. I am in the habit of using a posterior iron for this purpose, as advocated by Campbell, and find it very effective.

I have now operated on nineteen cases in this manner. The operation which I am to perform at the Children's Hospital this afternoon will be the twentieth of the series. Two patients have had a secondary operation for repair of the bone stop, which had fractured at a point where the scaphoid joined the other fragments, a few months after use of the foot had been permitted. Repair was carried out by means of a small bone pin driven through the stop. If any later cases need repair I intend to cut a strip of bone from the back of the tibia for the purpose. I shall also show this afternoon eight patients upon whom I did this operation more than a year ago, so that you will be able to judge of the stability of the feet and of the effect of the "bone stop" in preventing drop-foot.

THE TREATMENT OF AMOEBIIC DYSENTERY
BY AUREMETINE.

BY

J. GRAHAM WILLMORE, M.D., M.R.C.P.,

AND

W. HARRISON MARTINDALE, PH.D., PH.CH., F.C.S.

In a paper¹ read by us before the Royal Society of Tropical Medicine and Hygiene in May, 1923, the treatment and the results in a series of 503 cases of amoebic dysentery were detailed. It was shown that what might be termed the standard treatment in those days—consisting of 12 grains of emetine by intramuscular injection and 60 grains of emetine bismuthous iodide by the month, given concurrently in twenty days—was followed by a cure (as to the duration of which it was possible only to speculate) in less than one-third of the cases, and we

described the attempts which we had made to prepare drugs which, while pleasant to the patient, might prove more efficient in ridding him of his infection. It was considered that in emetol (a solution of emetine base in olive oil), administered by the rectum, in 6 drachms of ether and 12 oz. of olive oil, and in emetine periodide given by the mouth, we had advanced at least a stage nearer the goal. But the results were not deemed satisfactory, as more than one-third of the cases had relapsed in less than six months, and, as was anticipated, a much larger proportion have relapsed since.

It was therefore necessary to explore other trails, and we tried extensively preparations derived from sources other than ipecacuanha—such as activated quinine base, conesine, stovarsol, Bayer "205," a varied group of so-called intestinal disinfectants, flavine, etc. The results merely confirmed the opinion previously expressed, that efforts for radical cure must centre round emetine in some form or other. Yatren, given by the mouth and enema, caused much disappointment; in four refractory cases it had no effect, even as a temporary palliative. There has as yet been no opportunity of trying it by appendicostomy. Emetren (a compound of yatren and emetine designed for intramuscular injection) failed in the one case in which it was tried. Stovarsol alone held out some hope of success; when given by itself it was followed—even after the fullest course considered safe—by a greater proportion of relapses than was emetine periodide; but when given in combination with the emetine preparations decidedly better results were obtained than with either drug singly.

PHARMACOLOGY.

BY

W. HARRISON MARTINDALE.

Stovarsol is acetyl-amino-hydroxy-phenyl-arsenic acid. The emetine salt of this was prepared; it occurs as a sandy-coloured powder soluble in distilled water. Major H. C. Brown very kindly tested it on animals, and against glaucoma and a free-living amoeba. His results showed that a total concentration of 0.5 per cent. failed to kill glaucoma in fifteen minutes, and that amoebic growth was inhibited at 1 in 10,000, but not at 1 in 100,000. It was devoid of any bactericidal power at 1 in 1,000; a mouse weighing 24 grams died in one minute after the intravenous injection of 0.75 c.cm. of a 0.1 per cent. solution in saline, 0.5 c.cm. producing no symptoms. In another series of experiments 2 grains by the mouth made a cat weighing 2.2 kg. exceedingly ill for more than six days, although it did not kill it. It was not considered advisable to try it on human beings.

The potentialities of the aniline dye known as auramine are described in a series of articles² by Fairbrother and Renshaw, on the relation between chemical constitution and antiseptic action in the coal-tar dyestuffs. This substance is the hydrochloride of tetramethyl-diaminodiphenyl-ketonimine, and has the formula:

Fairbrother and Renshaw's experiments showed that this auramine killed paramoecia in fifteen minutes at 1 in 20,000, and it was only surpassed in this property by the Meldola blues, but as the most powerful of these, Meldola blue D (1 in 80,000, 1 in 160,000), contains zinc chloride, it was not further considered. (It is to be noted that the acridine class, with which we had experimented, are enormously less toxic to paramoecia.) They state that auramine killed twelve organisms (including anthrax) at 1 in 5,000 in fifteen minutes; small gold-fishes, however, lived in a solution of 1 in 20,000 for eighteen hours, whereas in brilliant green they died in ninety minutes. In the case of paramoecium, it is interesting to note that a 1 in 500 solution of phenol is necessary to kill in fifteen minutes, as against the 1 in 20,000 of auramine.

Experiments indicated a more moderate germicidal power, but 1 in 500 killed *B. coli* in seven and a half minutes, and we understand that this dye has been used clinically in surgical practice with good results, and without objectionable side-effects.

The next step was to attempt to prepare a compound

of auramine with emetine for oral administration, and after some technical difficulties, due to the rapidity with which the dye is hydrolysed when exposed in aqueous solution, a dark maroon powder, stable and insoluble in water, was prepared. This substance, for which the name "auremetine" is suggested, is a combination of the hydriodide periodides of emetine and auramine, and has approximately the following composition:

Emetine	28 per cent.
Auramine	16 "
Iodine	56 "

Its toxicity was as follows: a cat weighing 3.6 kg. was given a 2-grain capsule by the mouth. It vomited, and took little or no food for five days, its weight falling to 3.4 kg. Thereafter appetite returned, and on the eighth day its weight was 3.55 kg.

Major Brown reported:

"A fine emulsion was made of the insoluble powder (auremetine) in an agate mortar with a 6 per cent. gum solution, and its effect on washed glaucoma was investigated. A total concentration of 0.025 per cent. kills, but 0.005 per cent. fails to kill glaucoma in fifteen minutes. I also investigated the inhibitory action of this drug on the growth of free living amoebae. The varying dilutions were incorporated in the medium, which was planted with a culture of free living amoebae, and the results read after forty-eight hours' incubation at 20° C.:

Total Concentration in Medium.	Bacterial Growth.	Amoebic Growth.
1 in 1,000	+	0
1 in 10,000	++	0
1 in 100,000	++	0
1 in 1 million	++	+
1 in 10 million	++	++
Control plate without drug ...	++	++

Hence this drug is inhibitory to the growth of free living amoebae nearly to the same extent as emetine or conesine under the same conditions."

It is to be noted that the drug contains only 28 per cent. of emetine, the constituent most poisonous to the higher animals.

EFFECT OF PHYSIOLOGICAL ACID AND ALKALI.

In our previous paper we pointed out the readiness with which emetine bismuthous iodide was decomposed by physiological acid, contrary to the view then held, and the vomiting and signs of gastro-intestinal irritation—so commonly observed after its administration—were attributed to this fact. Auremetine, on the other hand, after treatment with 0.2 per cent. hydrochloric acid for four hours at 40° C., only gave 2.4 per cent. of base, removed from the preparation as hydrochloride. This is equivalent to a decomposition of about 5.5 per cent. of the auramine emetine periodide, the liberated base being a mixture of emetine and dye base. The presence of emetine was shown by Fröhde's reagent, which does not react with auramine, whereas all precipitants (such as Mayer's and Dragendorff's) react with both emetine and auramine. Subsequent treatment with physiological alkali for four hours at 40° C. resulted in the liberation of a further 8 per cent. of the mixed bases (equivalent to about 18.5 per cent. decomposition of the preparation). In the human intestine it is probable that an even more extensive decomposition occurs, since its administration is quickly followed by the passage of orange-coloured faeces.

THERAPEUTIC EFFECTS.

BY

J. GRAHAM WILLMORE.

The administration of auremetine has been practically free from any objectionable side-effects, such as vomiting, nausea, abdominal pain, or purging. It is also much less depressing than emetine administered hypodermically, and it is not necessary to keep the patient in bed on this account alone.

For many years past I have been in the habit of administering massive doses of bismuth subnitrate to amoebic cases, after the manner introduced by James and Deekes in the Panama zone, in addition to all other treatment. While I have never found this drug alone to cure—an opinion which, I understand, James and Deekes share—I have found it a most valuable adjunct to any and every form of specific anti-amoebic treatment, and particularly so in that now to be described. In the "acute" cases a heaped teaspoonful, stirred up in soda water, was given every three hours (during the day, not at night) for twenty days, and then three times daily for an indefinite period; in the cyst-carriers it was given three times a day from the beginning. Symptoms of poisoning were never observed, even when it has been continued for months.

The method followed since the summer of 1924 is roughly as follows, though, of course, it is modified to suit individual cases:

1. "Acute" cases—that is, those with blood, mucus, and *Entamoeba histolytica* in the stools, or found in scrapings at sigmoidoscopy—are given:

(a) Auremetine 1 grain in soft gelatin capsule four times daily after food, on alternate days for seven days, and then daily to a total of 40 or 60 grains ingested.

(b) Stovarsol 4 grains three times daily for seven days, on alternate days with the auremetine. Previously we gave 4 grains twice daily for ten days, alternating with the auremetine days, or even to fifteen days.

(c) On stovarsol days a rectal injection of emetol, 2 drachms (=1 grain emetine base), in ether 6 drachms and olive oil 12 ounces. (Time retained to be charted.)

(d) "Panama bismuth" three-hourly for twenty days, and then three times daily.

2. "Chronic" or cyst-carrying cases are given:

(a) Auremetine, and (b) stovarsol, on alternate days as described above.

(c) "Panama bismuth," three times daily before food.

3. When hepatic involvement is present 1 grain of emetine hydrochloride by intramuscular injection, on alternate days for six days (that is, 6 grains in all), may supplement or replace the emetol.

The necessity of controlling all cases by routine sigmoidoscopy must again be emphasized, not only because carcinoma may not infrequently develop in the site of an amoebic ulcer (eight such cases have been seen during the past five years), but also because areas of submucous amoebic infiltration, from which teeming amoebae may be scraped out by a sharp spoon, may be found after repeated microscopic examination of the stools has been negative.

The accompanying table gives the results of this treatment, together with the total amounts in grains of drugs used. When larger figures are given the original course was repeated, and in this connexion it must be pointed out that certain individuals may show an idiosyncrasy towards stovarsol, especially after repeated courses. At least one death from this drug has been heard of, and one case under treatment developed intense dermatitis with purpuric spots after only 8 grains. The practice of giving one tablet every three hours until twelve have been taken—as advocated by some—is dangerous, and has not been found to give better results than any other method. As a minor measure of precaution patients are given glucose (1 lb. in 1 quart of orange and lemon water, to be taken in twenty-four hours) daily, during its administration.

In the results column the word "Responded" has been deliberately chosen as being less committal than any other. By its use it is meant to convey that the patient regained his health, lost all clinical signs and symptoms of his disease (including sigmoidoscopic findings), that his stools were negative on repeated examination, and that so far as can be ascertained he has remained well and free from any evidence of infection for a minimum period, unless otherwise stated, of six months after completion of treatment. Experience proves that it is impossible to give a definite guarantee of permanent cure in a case of chronic amoebic dysentery; a man, who months or even years before it had been hoped was cured, may be readmitted to hospital a wreck, at the point of death from intestinal or hepatic amoebiasis.

It is to be remembered that the cases dealt with were the residue of pensioners infected during, or before, the great war, many of whom had been through every dysentery centre in the country. All that is claimed is

No. of Case.	Auremetine (gr. by mouth).	Stovarsol (gr. by mouth).	Emetine HCl (gr. by po.).	Emetol (gr. of base by rectum).	Result.
1	40	80	—	—	Responded.

27	40	80	10	—	Responded.
28	40	—	6	6	Responded.
29	40	80	—	—	Responded.
30	40	80	10	—	Responded.
31	40	80	10	—	Responded.
32	80	160	—	—	Responded.
33	100	—	—	—	In one course, responded.
34	48	96	—	—	Responded; diarrhoea +
35	40	80	—	6	Responded.
36	20	—	—	—	Responded; first case tried.
37	40	80	6	6	Responded.
38	100	—	—	—	Responded.
39	48	96	6	6	Responded.
40	100	248	5	15	Severe refractory case, responded eventually.

This gives a total of 37 responses out of 40, or 92.5 per cent., a figure which, we fear, later experience may show to be far too optimistic.

that the present method of treatment—especially the introduction of auremetine—has given some gratifying and more hopeful immediate results than any other essayed.

In conclusion, our sincerest thanks are due to Major Brown of the Wellcome Bureau for Scientific Research, for the generous help which he has given us in investigating the toxicity and protozoocidal powers of the numerous preparations we sent him. Also, we wish to express our grateful appreciation of the sympathy and encouragement shown to us in the prosecution of our studies by Sir Lisle Webb, Director-General of Medical Services, Ministry of Pensions, by whose permission this report is published.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

TWO CASES OF PERFORATED JEJUNAL ULCER.

THE following cases are of interest in that they emphasize the fact that gastro-enterostomy is not unattended by its dangers despite its present-day popularity. If there exists an "ulcer diathesis," it seems that this operation merely transfers the site of ulceration from one part of the alimentary tract to another.

CASE I.

A man, aged 38, was admitted to the Royal Infirmary, Liverpool, in March, 1924. The diagnosis of perforated duodenal ulcer was confirmed by operation; a posterior gastro-enterostomy was performed, and the man made an uninterrupted recovery.

In July, 1925, the patient was readmitted. He stated that there had been total absence of pain in the abdomen for seven months after the operation. At the end of this period he began to experience periodic attacks of generalized abdominal pain, occurring every three days and lasting for ten to fifteen minutes; the pain had no relation to food. Gradually the characteristics of the pain altered; it became localized to a point one inch below the umbilicus and began to show a definite relationship to food, coming on about four hours after a meal and lasting until another meal was taken. The pain was relieved by self-induced vomiting, and on several occasions it awakened him in the early hours of the morning. There was no history of melaena or spontaneous vomiting. A radiogram showed the gastro-enterostomy stoma to be acting normally, although a small residue was observed in the stomach six hours after the barium meal. The patient was discharged from hospital without operation.

On October 28th, 1925, the patient was again admitted with all the characteristic signs of an "acute abdomen." The only localizing signs were very marked superficial tenderness in the left hypochondrium and a dull ache between the shoulders. A provisional diagnosis of perforated duodenal ulcer was made.

At the operation a most interesting condition was revealed. A perforated jejunal ulcer, about the size of a sixpenny piece, was found on the posterior wall of the efferent loop of the gastro-enterostomy coil of jejunum about 1½ inches from the patent gastro-enterostomy stoma. The ulcer was enclosed by a purse-string suture. As the pylorus was found to be patent, admitting a thumb easily, an entero-enterostomy between the afferent and efferent loops of the gastro-enterostomy loop of jejunum was performed. The abdomen was closed with drainage, and the patient made an uninterrupted recovery.

In the latter half of January of this year he was again admitted with symptoms similar to those which succeeded his first operation. A laparotomy was performed and a second jejunal ulcer was discovered in close proximity to the gastro-enterostomy stoma. A partial gastrectomy, which involved three-quarters of the stomach and the whole of the loop of the jejunum taking part in the gastro-enterostomy, was performed; the man made an absolutely straightforward recovery.

CASE II.

A man, aged 37, was operated upon in the Royal Infirmary, Liverpool, for a juxtapyloric ulcer in March, 1925. A posterior gastro-enterostomy was performed, and the patient made an uneventful recovery.

In January, 1926, he was again admitted to the hospital with signs suggestive of a perforated duodenal ulcer. The abdomen was opened, and a perforated jejunal ulcer was found on the efferent loop of the gastro-enterostomy coil of jejunum. The perforation was the size of an orange-pip. The edges of the ulcer were excised and the gap was sewn up in the transverse axis of the bowel. The gastro-enterostomy stoma was found to be quite patent. The abdomen was closed with drainage, and the patient made an uninterrupted recovery.

I am indebted to Professor R. E. Kelly, senior honorary surgeon to the Royal Infirmary, Liverpool, and to Mr. R. Kennon, senior assistant surgeon to the same hospital, for permission to report these cases.

ALFRED T. ASHCROFT, M.B., Ch.B.,
House-Surgeon, Royal Infirmary, Liverpool.

ACUTE SUFFOCATIVE PULMONARY OEDEMA.

As I have observed a patient who typically illustrates this somewhat rare condition, I think it would be of interest to record his case.

The man is a printer and is 33 years of age. He has valvular disease of the heart, the aortic and mitral valves being incompetent. The heart is enlarged, and there is conspicuous pulsation of the carotid arteries. His countenance is strikingly pale, and the pulse is of the collapsing type. The lungs, however, are clear, and there is no oedema of the ankles; but the urine contains some albumin. The systolic blood pressure is 150, and the diastolic 80 mm. of mercury. The cardiac affection dates from an attack

of rheumatic fever at the age of 16, and does not interfere with his following his occupation, which does not involve much exertion.

During the past year and a half he has had four attacks of acute, or rather hyperacute, oedema of the lungs. They have all occurred in the middle of the night and presented the same features. On arrival I find him sitting propped up in bed, anxious-looking and cyanosed, and constantly expectorating a frothy serous fluid which comes up without any effort. Coarse moist râles are heard everywhere over the chest. The pulse is rapid and forcible. He is fully conscious and repeatedly asks for something to be done quickly to relieve him of his distress, which appears to be a feeling of impending suffocation, for he is literally drowning in his own secretion. His extremities are cold. The application of a hot-water bottle to his feet, a hypodermic injection of atropine gr. 1/50, followed later by morphine gr. 1/4, render him more comfortable. The following morning he feels quite well.

The attack comes on without any warning, waking him from his sleep, and usually lasts several hours, during which time he brings up a couple of pints of the watery, pinkish-tinged, frothy fluid, the coloration being most obvious in the froth. The condition is ascribed to a sudden transient relative failure on the part of the left ventricle.

London, E.

M. COHEN, M.B., Ch.B.Glas.

TREATMENT OF SEPTIC TUBERCULOUS ARTHRITIS.

I wish to invite attention to a method of treatment which I have found efficacious for some septic tuberculous joints which at first appeared beyond hope of salvation. It is based on the assumption that the patient's power of repair is not absolutely bankrupt; in such a case there is only one living chance—amputation.

The method is as follows: Administer ether by the open method. Apply a tourniquet well proximal to the lesion. Lay open by free incisions all sinuses, and fully expose the interior (and recesses) of the joint. With strong scoops and scissors remove every visible particle of diseased bone and tissue. Establish, whenever possible, large gravity drainage tunnels. Irrigate copiously with warm hydrogen peroxide (1 in 17) carbolic (1 in 70) lotions. Introduce large wisps of silkworm gut through tunnels, and pack meticulously the rest of the cavity with rolls of gauze wrung out of freshly prepared iodoform emulsion. Secure the limb in absolute rest on a suitable splint in the position which ultimately will be most useful. After forty-eight hours flush out twice daily with "peroxide carbolic" reinsert wisps, and repack with iodoform gauze; it may be necessary to remove the splint for each irrigation during the first weeks. Place the patient in an outdoor balcony, and give plenty of nutritious food plus some alcoholic beverage with meals. The part is maintained in absolute rest, and the patient is continuously out of doors until the wounds have soundly healed and x rays demonstrate healthy ankylosis.

In case of scepticism as to the power of chemical disinfectants in these desperate cases I beg for a fair trial of the above-mentioned combination, which, in conjunction with free gravity drainage, will within one month yield a display of bright vermilion granulations which will worthily uphold the teaching of Lister.

Buenos Aires.

JOHN O'CONNOR.

APPENDIX IN LEFT INGUINAL HERNIA.

THE following clinical details seem to be of sufficient interest to merit publication because the appearance of the appendix in a left inguinal hernia must be very rare.

A man, aged 24, was admitted to the Dewsbury and District General Infirmary on February 20th, 1926, with strangulated left inguinal hernia. The history was that during the previous five years a lump had often appeared, which he had always reduced himself. He had not worried about it, nor obtained medical advice. On the date mentioned, however, he was unable to reduce it, so came into hospital. The hernia was found to be of a fairly large size, extending well into the scrotum. Manipulation was tried, but it was found impossible to reduce it; an operation was therefore performed at once, and a large thin-walled sac was found to contain the terminal portion of the ileum, the whole of the caecum, with the appendix, and the first inch of the ascending colon. Although this was found on the left side there was no other evidence of any transposition of the viscera. No adhesions were present, and the appendix was easily removed, a radical cure being performed.

G. FOSTER SMITH, L.M.S.S.A.Lond.

Reports of Societies.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.

At a meeting of the Nottingham Medico-Chirurgical Society held on February 25th, the President, Mr. H. BELL TAWSE, in the chair, an address was given by Sir GEORGE NEWMAN on the relation of the State to medicine.

The Relation of the State to Medicine.

Sir George Newman said that it was convenient to divide the long history of medicine into four principal divisions—the age of Hippocrates, which contained also the pre-Hippocratic period; the 500 years between Hippocrates and Galen; the 1,400 years from Galen to the Renaissance; and the modern period ushered in by the Renaissance. Each of these periods was full of interest, but it was significant that the science and art of medicine had only been organized in the public benefit during the last hundred years. Such organization was brought about partly by the need for the State to protect itself against the great pestilences of plague, leprosy, and cholera, partly by the growth of the Elizabethan Poor Law and regard for the condition of the people, partly by the extraordinary expansion of medical knowledge, and partly by the evolution of human society. The public medical services now instituted in Britain constituted the most complete and comprehensive effort on the part of the State in the whole range of history; moreover, the services in this country were more established than in any other country in the world. They consisted of six branches—namely, the Poor Law medical service, the public health service, the medical supervision of factories and workshops, the school medical service, the national health insurance system, and the maternity and child welfare service. Nor must it be forgotten that these services were in addition to medical services for the Army, Navy, and Air Force, and for the Colonies and India. They were also exclusive of the steadily growing imposition by Parliament of statutory duties upon the medical practitioner. These public medical services were not originated by the Government and laid upon the medical profession; they were originated by medical practitioners themselves in the eighteenth century. There was no more instructive chapter in English medicine than the persistent and, on the whole, triumphant, achievement of medical practitioners in this behalf. This organization of medicine had been contributory to a greatly reduced death rate, an amazing fall in the infant mortality rate, a steady decline in pulmonary tuberculosis, a disappearance of the great pestilences, and a rise in the expectation of life. Yet there was much left to be done; 40 per cent. of the people died under 50 years of age, many of them suffered continuously from invalidity, and the amount of time lost owing to preventable sickness was greater than the total time lost owing to all industrial strikes and lock-outs added together. A study of the health insurance records showed that 23½ million weeks of time were lost by the insured population in 1924, the great bulk of it being due to what might be thought of as relatively minor ailments. Something like 20 per cent. of the sickness which brought insured persons to their doctors in that year was attributed to bronchitis, nasal catarrh, and the common cold; 14 per cent. to lumbago, rheumatism, and neuralgia; 12 per cent. to indigestion; 10 per cent. to slight influenza; 10 per cent. to avoidable injuries; and 7 per cent. to local septic conditions. Thus 73 per cent. of the sickness returns was accounted for. There was another aspect of these medical returns which was full of interest; it raised the four great questions which every practitioner from immemorial times had been asked by his patient to answer. What is the matter with me? (diagnosis); Can you put me right? (treatment); When shall I get well? (prognosis); and, How can I avoid this illness in future? (prevention). It was to these four ancient conundrums that they must still address themselves in modern medicine. They were only the heirs of the work of their forebears in the eighteenth century, but because of that early work the modern medical practitioner had many advantages. The doctor now obtained his patient earlier; instruments of precision were provided; facilities of treatment were available; he had a

larger experience of prognosis; the causes of disease were now better known; and last, and most important, methods of prevention had been made possible.

Abdominal Disorders in Childhood.

At the next meeting, on March 4th, the PRESIDENT in the chair, Dr. F. J. POYNTON, physician to University College Hospital and the Hospital for Sick Children, Great Ormond Street, introduced a discussion upon some abdominal disorders in childhood.

Dr. Poynton commenced with the subject of infant feeding, and asked whether the longer intervals between feeds now in vogue did not tend to make feeble though otherwise sound infants overhungry, to gulp down their feeds, and so to favour spasm and flatulence. He did not think this happened with the strong infant, but it was his experience that it did with the delicate and ailing. He dwelt upon the use of protein milk and foods not containing milk, and upon their value in the difficult stage of acute gastro-enteritis, and in chronic diarrhoea when return to normal feeding had to be started. He gave his experience of hypertrophic stenosis of the pylorus, and from a series of 80 cases showed that, by the combination of prompt surgery with skilled nursing and dieting, his mortality rate had fallen from 70 to 6 per cent. He emphasized the importance of palpating the tumour. After touching upon pylorospasm, he passed to the dieting of coeliac disease, and expressed the opinion that in some cases, not only was fat not digested, but that all the food elements were badly assimilated, and, in addition, the amount of food had to be much restricted. Acetonaemia was then considered, and the two prominent features of such cases illustrated—the nervous feature by examples of tram and train sickness, night terrors, and other evidences of nervous instability, and the alimentary feature by the rare though clear-cut examples in which acetonaemia was diagnosed as the primary illness, but the actual cause was found to be volvulus of the small intestine. In classical cases of cyclic vomiting acetonaemia might precede the vomiting, though in his experience that was exceptional; he thought that the evidence pointed to some pre-acetone body as the essential poison. He concluded by showing drawings and radiograms of the condition of chronic intussusception and commenting upon the difficulties in the diagnosis.

DEVON AND EXETER MEDICO-CHIRURGICAL SOCIETY.

A CLINICAL meeting of the Devon and Exeter Medico-Chirurgical Society was held on February 25th, the President, Mr. R. WORTHINGTON, being in the chair.

The PRESIDENT showed a girl, operated on a fortnight previously for acute mastoiditis. There was profuse purulent otorrhoea and a large red oedematous post-aural swelling. The tonsils were large and septic, and the otorrhoea of six weeks' duration. At operation the whole mastoid process was found to be a shell of pus. The wound was treated with bipp and completely closed; the tonsils and adenoids were removed at the same time. The stitches were removed on the seventh day, when there was no otorrhoea and the wound was perfectly healed. The case was shown to illustrate the greatly improved outlook afforded by bipp in the after-treatment of such cases. Mr. A. L. CANDLER sounded a word of warning as to the use of bipp in larger cavities where iodine poisoning was liable to arise. Here, however, the procedure had proved not only safe but most reassuring. Mr. WAYLAND SMITH referred to the researches of the late Professor A. R. CUSHNY, which went to prove that it was the paraffin, and the paraffin alone, that was the curative agent in the bipp combination. Mr. WORTHINGTON, in replying, added that it was most important for ensuring success that all vessels should be twisted off to avoid leaving ligatures in the cavity.

The PRESIDENT, in conjunction with Dr. F. A. ROSEN, showed a middle-aged woman with a very large parenchymatous goitre, partly cervical and partly intrathoracic; the intrathoracic portion was proved by x rays to be exceptionally large. Mr. N. LOCK referred to a paper

by Sir Charles Ballance where division of the clavicle was recommended in order to allow the tumour to be raised up from the thorax. Mr. CANDLER considered the symptoms were becoming urgent, and, failing x-ray treatment, operation appeared to offer the only chance. He raised the question of intubation as a preliminary to the operation. Mr. WORTHINGTON agreed that the dyspnoea and dysphagia present in the case justified the risks entailed by operation, and he should most certainly intubate in the first instance, probably making use of a large No. 12 White Porget's catheter.

The PRESIDENT also showed a woman with swelling over the frontal bone. In spite of the negative Wassermann reaction he proposed treatment with the iodides.

Dr. R. K. FOULKES showed a gardener, aged 46, who contracted encephalitis lethargica in May, 1924. The initial symptoms were headache, diplopia, insomnia, and nocturnal delirium; he was never very drowsy. The Parkinsonian syndrome had been established for the past twelve months, and included the immobile facies; rigidity of neck muscles and fixed forward position of the head; very slight rhythmic movement of the head; a pill-rolling attitude of the right hand; and a tremor of the right arm, less marked now than formerly. There were also present katatonia, excessive salivation, and unequal pupils, with sluggish reaction to light and loss of accommodation. Furthermore, puffiness of the face and neck and excessive sweating of the scalp were suggestive of hypopituitarism.

Mr. CANDLER showed a girl with Sprengel's affection of the shoulder. He discussed the pathology of the condition, mentioning the intrauterine pressure theory and the possibility of injury at birth. The resultant deformity was on a par with shortening of the trapezius. The accompanying deformity of the chest was demonstrated, and this might be remedied to some extent by exercise and massage, but in Mr. Candler's opinion operation was not advisable.

Dr. F. A. ROPER showed a girl, aged 18, with congenital haematoporphyria. In addition to the typical pigment in the urine, there was a bullous eruption on the hands, light sensitivity, scaling of teeth, and pigmentation of bones. Sir Archibald Garrod, who had taken an interest in the case, had supplied the technical outfit necessary for estimating fluorescence of the bones; this test had proved negative. The face was very hairy, and the hands those of an old woman. The blood examination showed 3,500,000 red blood cells, with an increase in megaloblasts; the leucocytes were normal and the haemoglobin 70 per cent. Dr. Roper, in outlining the disease, described it as an inborn error of metabolism; the prognosis was unfavourable. As regards the experimental side, guinea-pigs infected died if not protected against light. A foreign professor who infected himself developed severe symptoms typical in their association. Dr. R. EAGER mentioned a case of the acquired form of the disease caused by the abuse of sulphonal.

Mr. R. WAYLAND SMITH showed a youth, employed as a fireman at a gasworks, admitted to the Royal Devon and Exeter Hospital on January 1st, 1926, suffering from carbon monoxide poisoning and extensive burns of the gluteal region. The case was shown for the purpose of demonstrating the possibilities of covering large areas of granulating surface with Reverdin "islet" grafts. About a hundred grafts were taken, and all of them took root. The surface would have proved too extensive for an ordinary Thiersch graft. It was essential for success that the area to be grafted should be clean and flat. In this case the raw surface had been treated with flavine and eusol and then with normal saline solution; as a preliminary to grafting it had been washed with methylated ether and finally with normal saline.

Mr. Wayland Smith also showed a case of pancreatic cyst related to acute pancreatitis in a middle-aged woman who had been admitted on two occasions to the Royal Devon and Exeter Hospital.

On the first admission (July 2nd, 1925) there was a history of two days' severe abdominal pain at the level of the umbilicus, and of vomiting. Beyond enteric, fourteen to fifteen years ago, there was nothing of import in her previous history. On admission the temperature was 98°, the pulse rate 120, and respirations 30. It was noted that the abdomen was distended, moved poorly, and that there was a tender lump about the size of a fist in the

umbilical region. The operation disclosed fat necrosis of the omentum, a small amount of free fluid and blood, no pus, and a normal gall bladder. Cholecystostomy was performed, and the gall bladder drained; the bile proved to be normal. In August there appeared a tumour in the left upper half of the abdomen, causing compression of the base of the left lung. A diagnosis was hazarded of a cyst arising from the tail of the pancreas. About this time she was again given a general anaesthetic, and the sinus to the gall bladder enlarged. The urine, examined on August 25th, showed a diastatic index of 40, and the faeces gave the following analysis: Total fat 29.04 per cent., neutral fat 24.08 per cent., fatty acids 4.96 per cent.

She was discharged on September 17th, but readmitted on February 7th, 1926, with severe pain, respiratory embarrassment, and vomiting. The symptoms appeared to increase directly with closure of the sinus, and this had remained closed for two days prior to her readmission. Examination showed a very large cyst bulging in the left loin. Laparotomy was performed, and the cyst was located immediately behind the stomach. An opening was made through the gastro-colic omentum, and the lower border of the stomach was turned up, the abdomen being packed off. The cyst wall was densely adherent to the posterior wall of the stomach, and rupture occurred during dissection, with expulsion of cyst contents. A counter-opening was made into the left loin, and the edges of the cyst opening were sutured to the parietal peritonium. Large drains were placed in both openings. The cyst fluid was odourless, thin, brownish-green in colour, and slightly alkaline. Mucus was present in a considerable amount, and blood corpuscles were very numerous. Bile pigment was absent, proteins, diastase, and lipase were present, and there was a trace of trypsin. Fatty acids were numerous, but there was no cholesterol. The woman was still an in-patient with the sinus persisting, great care having to be taken as regards protection of the skin.

Mr. CANDLER discussed the case, the first admission having been under his care for acute pancreatitis. The closure of the gall-bladder sinus undoubtedly had an unfavourable effect by promoting back pressure on the pancreas.

THE BLOOD PLATELETS IN DISEASE.

At a pathological meeting of the Liverpool Medical Institution on February 25th, Dr. J. C. M. GIVEN, the President, in the chair, numerous specimens were exhibited, and Dr. W. HOWEL EVANS read a paper on recent advances in knowledge of the blood platelets, with special reference to haemorrhagic diseases and pathological thrombosis.

Dr. Evans discussed the evidence as to the origin and specificity of the platelets, mentioning especially the experimental work of Ledingham, Bedson, and Robertson, which afforded final proof that platelets were separate blood elements. Their morphology and a simple method for enumeration were described. Apart from their known function in connexion with blood coagulation, their importance in preserving capillary tone was emphasized; capillary leaking and increased bleeding time were associated with deficiency, while when the platelet count was very high the capillaries seemed to be tightened up, and the bleeding time was much diminished. The phenomena associated with thrombocytopenia or platelet deficiency were enumerated as slightly delayed coagulation time, prolonged bleeding time, failure of clot retraction, diminished capillary resistance, and spontaneous capillary haemorrhage. Dr. Evans showed that in a series of ten cases of primary and secondary purpura, with low platelet counts, the coagulation time, though usually stated to be normal, was in reality moderately delayed. The delay, however, did not approach that met with in haemophilia, where the platelets were normal in numbers, but qualitatively abnormal. The causes of thrombocytopenia were classified, and the primary disease, idiopathic purpura haemorrhagica, was discussed, with particular reference to splenectomy in this condition. The post-operative results of the reported cases were summarized, and two recent cases of splenectomy in Liverpool were described in detail. Dealing next with conditions associated with rise in the platelet count, Dr. Evans pointed out that clinically in certain of these conditions—namely, the convalescent period after infections such as typhoid and pneumonia, chlorosis, and certain forms of splenic anaemia—spontaneous thrombosis frequently occurred. Further, in a series of six cases after splenectomy he had observed a definite shortening of coagulation time associated with the high platelet counts. In one of these cases—splenic anaemia of the Banti type—the platelet count persisted after splenectomy at a level of about a million and a half until the thirtieth day, when the patient died from mesenteric thrombosis. Similar

fatalities after splenectomy in splenic anaemia associated with persistently high platelet counts had also been reported by Rosenthal. These facts showed a definite correlation between high platelet levels, shortened coagulation time, and clinical thrombosis, and emphasized the need for study of the platelet factor in relation to all cases of pathological thrombosis.

SARCOMA OF THE SPINAL CORD.

At a meeting of the Section of Medicine of the Royal Academy of Medicine in Ireland on February 26th, the President, Dr. F. C. PURSER, in the chair, Dr. V. M. SYNGE read a paper on a case of spinal tumour, the main points of interest in the case being the slight and transient pain, accurate localization by lipiodol, and the improvement after the surgical removal of the tumour. The details of the case were as follows.

A woman, aged 39, was admitted to hospital last August complaining of inability to walk. In the previous April she had had a pain in the right side which disappeared in a few weeks; in the beginning of July she noticed that her left leg felt tired and weak; the right leg became similarly affected a month later. On admission her legs were spastic, very weak, and not wasted. There was loss of sensation to pin-pricks, cotton-wool, and to heat and cold to slightly above the umbilicus, with the exception of areas on the front of the right leg and the outer aspect of the left leg, where sensation was normal. Abdominal reflexes were absent. Both legs showed exaggerated knee-jerks, ankle clonus, and extensor plantar reflex. The sphincters were normal. There was nystagmus, but the eyes were otherwise normal. The Wassermann reaction was negative, and a radiograph of the spinal column appeared normal. On September 8th incontinence of urine commenced, and on September 14th there was loss of sensation from just above the level of the nipples, there being no areas of normal sensation below this. On September 18th lumbar puncture was performed; the fluid was clear, pale yellow, and not under increased tension. It clotted on standing, the globulin was increased, but the cell count was normal. On September 25th 1 c.cm. lipiodol was injected into the cisterna magna, after removal of 3 c.cm. clear colourless fluid which did not clot; an x-ray photograph showed the lipiodol arrested at the level of the first thoracic vertebra. The patient had frontal headache with pyrexia for twenty-four hours after injection. On October 3rd a tumour 2½ in. long was removed. It extended from the level of the first thoracic vertebra downwards, posterior to the denticulate ligament; it was adherent to the arachnoid and dura in places. Microscopic examination proved the tumour to be a sarcoma. Four weeks after the operation the patient felt pain in the left leg with some return of sensation, and x-ray treatment was directed to the site of the tumour by Dr. Hardman. Four and a half months after the operation the sensation over the trunk had become normal; sensation was absent over the right leg except for a small area on the foot, and sensation in the left leg was present but impaired. There was no voluntary movement of legs, but involuntary automatic movements were present; the reflexes in the legs were absent, there was incontinence of faeces and urine, and a healing bed-sore in the sacral region. Nystagmus was still present; its cause was unexplained. The operation scar was satisfactorily healed.

The great improvement following operation in this case was noteworthy, and were it not for the malignant character of the tumour a good functional result might have been expected.

The PRESIDENT said that he had seen the patient while she was in hospital and had suggested the use of lipiodol as the diagnosis of spinal tumour was not absolutely certain; in most cases of spinal tumour the condition could be diagnosed accurately by the clinical signs. In the cases of spinal tumour that he had seen, although the patients lived for years and became no worse, still they did not improve; and he had never seen such an improvement in the symptoms after operation as in this case.

Dr. A. R. PARSONS referred to the rarity of cases of tumour of the spinal cord, and said that at the last meeting of the Association of Physicians Sir James Purves-Stewart had demonstrated a case in which very marked improvement had followed surgical treatment. Before the operation the patient had been paralysed, and subsequently he was able to walk. In this case also the disease had been localized by lipiodol. He asked if in Dr. Syngé's case the removal of the tumour had had any effect on the nystagmus, and also what had happened to the lipiodol.

Dr. L. ABRAHAMSON said that in one case of his in which lipiodol had been given the patient had been radiographed a month later, and the lipiodol was seen to be still at the bottom of the spinal canal. He thought that lipiodol was dangerous, and that it should be given only in cases in which a diagnosis could not be made otherwise.

Dr. SYNGE, in reply, said that at the operation the lipiodol had been found exactly where it had been shown to be present by x rays, and had escaped in oily drops, which had not caused any inconvenience during the operation. Sometimes lipiodol was given by lumbar puncture, and the patient was left with the head lying lower than the feet; in these cases it was dangerous, as the lipiodol sometimes entered the brain; otherwise he thought that the reaction after an injection was only temporary. The nystagmus was still present.

Lymphosarcoma of the Lung.

Dr. F. J. O'DONNELL read notes on two cases of lymphosarcoma of the lung.

Case 1.—A man, aged 64, who had been in good health up to three months before admission to hospital, complained of extreme breathlessness on slight exertion. Cyanosis, emaciation, and clubbing of the fingers were all well marked. The glands in the right axilla were obviously enlarged and hard, while in the abdomen, below and to the right of the umbilicus, was a bluish tumour as large as a turkey's egg. The right side of the chest was completely immobile and dull, with high-pitched tubular breathing audible throughout; it was reported by the radiologist to be filled by a dense immobile mass. The patient died a week after admission, and at the necropsy the right side of the thorax was found infiltrated with a hard greyish mass, the removal of which, as a whole, was found impossible. This tumour was reported to be microscopically a lymphosarcoma and the axillary and abdominal tumours were secondary growths.

Case 2.—A man, aged 34, had complained of "chest trouble" for some years, and became acutely ill a few days prior to admission to hospital. The temperature was 103°; there was deficient movement of the right side of the chest, with dullness and harsh tubular breathing throughout. Pneumonia was diagnosed and a crisis occurred, but it was rapidly followed by regular evening pyrexia. Exploration of the chest for pus was negative, but x-ray examination showed that the right lung was immobile. Despite the persistence of the signs in the chest, the patient steadily improved and was able to sit up for a few hours; he then died suddenly in the seventh week after admission. At the necropsy the right pleura was found as thick as good chamois leather, the right lung had the appearance of tuberculous bronchopneumonia, there was a small consolidated empyema at the right base, and the mediastinal glands were very hard. The pathologist reported that it appeared to be a case of lymphosarcoma. The lung showed a long-standing condition of fibroid phthisis and, on the pleural surface, was being secondarily infiltrated with sarcoma cells.

Dr. A. R. PARSONS said that primary sarcoma of the lung was a very rare condition. He thought that in cases of malignant disease of the lung nothing could be done to give the patient more relief than either radium or x-ray treatment. He mentioned two cases of his own, in which great temporary improvement had followed the application of radium, although both patients had ultimately died. In one case at the necropsy it was found that what had originally been diagnosed as lymphosarcoma was a mass of fibrous tissue, with a few cells embedded in the centre.

Dr. R. H. MICKS referred to the difficulty of diagnosing these cases, and the help that was obtained by x rays in diagnosis.

Dr. V. M. SYNGE thought inequality of the pupils was often a very valuable sign of an early intrathoracic growth. In Dr. O'Donnell's first case there had been clubbing of the fingers, and he asked if Dr. O'Donnell thought that this was due to the tumour. He had recently seen a patient with clubbing of the fingers, but no pulmonary disease whatever. Regarding the difficulty of diagnosis, he said that he thought the danger was that lymphosarcoma was too often diagnosed when it was not really present at all.

Dr. E. T. FREEMAN considered radium very useful in these cases, at any rate for temporary relief; he mentioned a case in which a year previously a tumour had been found in the upper portion of the left lung, with dilatation of the left pupil and swelling of the left side of the face. The patient had had three deep x-ray treatments, and the tumour had now disappeared. How long the improvement would last it was, of course, impossible to say.

Dr. O'DONNELL, in reply, said that mediastinal tumours were much more common than any other form of intrathoracic growth. Inequality of the pupils was, he thought, a sign of a primary mediastinal growth, but this was not present in either of his cases. In secondary cases he felt that x-ray treatment only resulted in the air space being decreased, and that this hastened the patient's death. In primary mediastinal growths x rays were, however, certainly efficacious.

Reviews.

MUSCULAR ACTIVITY.

PHYSIOLOGY has already conceded to biochemistry and to that younger Napoleon, biophysics, a permanent seat at her councils. From Professor A. V. HILL's *Muscular Activity*¹ a new voice is heard claiming a place at the round table. This new invader—let us rather call him ally—hails from the engineering shops and the drawing table, and speaks the language of mechanics and of thermodynamics.

The volume comprises the Herter Lectures delivered at Johns Hopkins University in 1925. To execute the obligations of this lectureship a distinguished succession of European experimenters in the medical sciences have crossed the Atlantic. The benefit of their journey we share with them and with their audiences, for we receive in the printed lectures a most valuable series of monographs. Professor Hill's four lectures bring together the earlier experimental work of the author and his colleagues and recent applications—particularly to muscular exercise in man—which he has inspired a large body of disciples to pursue.

Professor Hill is, indeed, a man of muscle. For more than a decade he has been engaged on a delicate analysis of the mechanical and thermal response of muscle in the laboratory. He tells us, however, that his first apprenticeship to the problem was still earlier and in other surroundings, for the chief satisfaction of his youth was in the arduous and endurance of the cinder track; and now, ever and again, he escapes from the laboratory to test his convictions on that man who is after his own heart—the athlete. The athlete condemns none of his conclusions.

The first lecture describes some recent work from the author's laboratory on the mechanics of muscle contraction. With the aid of a pretty ingenuity in the construction of apparatus, with stress-strain diagrams, and efficiency determinations, we are led to the conception of the muscle as a viscous elastic system wherein the mechanical response is a sudden reversible gelation of some constituent of the muscle fibres.

But the mechanical response is but the final expression of those immediate responses to stimulation which must find their explanation in chemical terms. For the chemical analysis of the muscle process at first hand thermal methods alone are of a delicacy appropriate to the changes which occur. Again we marvel at the beautiful technique evolved to suit the special problem. A muscle is stimulated, a galvanometer deflects, and a curve is recorded on a moving photographic paper. From these reluctant curves is drawn the story of the muscle process. There are to be distinguished two phases—an anaerobic production of lactic acid followed by an aerobic restorative process. Contraction accompanies the anaerobic process, whilst the complete cycle restores the muscle to its initial state. In the absence of oxygen the muscle is driven inevitably towards fatigue. In his emphasis on the fundamental character of the anaerobic function of muscle Professor Hill perhaps scarcely gives the early chemistry of fermentation its due. Did not Pasteur appreciate that in the anaerobic fermentation by yeast he was observing an almost perfect substitute for respiration?

The remarkable confirmation and elaboration of the story by the chemical researches of Meyerhof forms the material of the third lecture, whilst in the fourth we see the frog discarded and the athlete becomes the subject of study. We learn that the sprinter is essentially an anaerobic machine running into "oxygen debt" to the extent of many litres in a few seconds and accumulating lactic acid at a rate of 4 gm. a second. The long-distance runner, on the other hand, may not so rashly expend his capital, but must live within his oxygen income, so that his achievement is determined by the efficiency of his oxygen supply. How this may be controlled by the coronary circulation, what is the physiological limit of violent exercise, what is the immediate fuel of the muscle, wherein

resides muscular efficiency in man—these are topics of wide interest indeed.

These lectures describe a romance of the laboratory and of the field, and we suspect that Professor Hill is just as happy with a stop-watch by the cinder track as he undeniably is with a thermopile and the sartorius of a frog.

MIGRAINE.

DR. F. G. CROOKSHANK has written an attractive little book on *Migraine and Other Common Neuroses*.² Whatever the view that may be taken by the reader on the hypothesis that is put forward in this work, there can be no doubt that the reading of the book will stimulate thought. The author takes for his text a saying in Burton's *Anatomy of Melancholy*: "Socrates, in Plato, would prescribe no Physick for Charmides' headache till first he had eased his troublesome mind; body and soul must be cured together, as head and eyes," and then proceeds to show that there is a vast range of cases in which the psychical and physical disorders seem, as it were, nearly balanced. Such cases are apt to be dismissed as "functional"—a term that does not help the patient much.

Dr. Crookshank seeks to show the primary importance of the psychical aspect of the illness. The disturbances reveal either constitutional or local inferiority, to which may be transferred an emotional feeling that rightly pertains to something in the psychical life. The first part of the book is a metaphysical discussion of the general ground for this belief. The second part is the definite application of the theory to migraine and other similar disorders.

The author accepts the influence of local conditions upon the production of these attacks, such as errors of refraction or inequality of the eyes and muscular imbalance; he accepts also the influential facts of general metabolic disorders as a predisposing influence in the production of the attacks; he recognizes also the greater frequency of the attacks among the intellectual workers, and particularly the males; and often, very often, among those who make a distinct success of their lives. The acceptance of all these factors in the make-up of the liability to the attacks would seem to rule out some part of his thesis—at least if he means by it what is the general connotation of his terminology. He believes that the attacks reveal "either constitutional or local inferiority." The latter belief may be accepted without hesitation if it means the effect of an overstrained because weak organ, such as results from too close eye work with uncorrected errors of refraction. But he means much more than that. He suggests that there is what is commonly known as an "inferiority complex"—that the subject by some psychic process retreats to the shelter of a violent attack of migraine to escape the feeling of inferiority inherent in his mental make-up. This argument has to be placed alongside the fact that attacks are common in young and vigorous men, those who are making real strides to success in life, and who ultimately make their mark in their day and generation. They are not the social actresses of the novel writers who find a happy retreat from some disliked obligation in an attack of the megrims. They are far too honest with themselves for such disguises, neither is there any necessity for them. The fact that many sufferers from these attacks carry on during and despite these visitations negatives the idea.

But, as we have indicated, whatever view be taken of the thesis, the little book is worth reading. It is the first of a new series of "Psyche Miniatures," of which others are in preparation.

CLINICAL RESEARCHES IN ACUTE ABDOMINAL DISEASE.

MR. ZACHARY COPE's *Clinical Researches in Acute Abdominal Disease*³ is a collection of nine essays on different aspects of abdominal disease. Most of the chapters are an expansion of the Arris and Gale lecture delivered by the author

¹ *Migraine and Other Common Neuroses: A Psychological Study.* By F. G. Crookshank, M.D., F.R.C.P. Psyche Miniatures, Medical Series, No. 1. London: Kegan Paul, Trench, Trubner and Co., Ltd. 1925. (Double post 16mo, pp. 101. 2s. 6d. net.)

² *Clinical Researches in Acute Abdominal Disease.* By Zachary Cope, B.A., M.D., M.S. Lond., F.R.C.S. Eng. Oxford Medical Publications. London: H. Milford, Oxford University Press. 1925. (Demy 8vo, pp. xiii + 148; 29 figures. 12s. 6d. net.)

³ *Muscular Activity.* By Archibald Vivian Hill, M.A., Sc.D., F.R.S. London: Baillière, Tindall and Cox; Baltimore: The Williams and Wilkins Company. 1925. (Demy 8vo, pp. viii + 115; 12 figures. 12s. 6d. net.)

in 1922. Two of the other chapters are reprints of contributions made to the *BRITISH MEDICAL JOURNAL*.

The first chapter contains a justification for the title of the book, and in it the author explains what, in his opinion, should be the scope of clinical research. There are, he says, three main purposes to which clinical research may reasonably and adequately be directed. The first of these is to test with thoroughness the results achieved by work in the laboratory; the second, to try various empirical methods and to furnish the results to the laboratory for explanation and elaboration; and the third is to record and compare clinical facts with the object of determining some questions which are inaccessible to laboratory methods of study.

The remainder of the book is concerned with more practical questions. The second chapter discusses the function of the parietal peritoneum in the localization of abdominal pain, the fourth cutaneous hyperaesthesia in acute abdominal disease, and the fifth is a clinical study of phrenic shoulder pain. The author's views on the difficult subject of subacute perinephric abscess occurring without disease of the kidney are well set out in the last chapter.

EXPERIENCES IN SURGERY.

THE two final volumes of *Practical Surgery Illustrated*,⁴ by M. V. PAUCHET, have now appeared. As in the case of the first four volumes, of which a review appeared on February 28th, 1925 (p. 413), the translation has been made by Dr. F. R. B. ATKINSON, and each has an introduction by Sir CHARLES GORDON-WATSON. They maintain the standard of their predecessors, and the illustrations of each step of the various operations described are so good that in many cases it is scarcely necessary to refer to the short and concise accounts which accompany them.

In Vol. V, dealing with the treatment of trigeminal neuralgia, Pauchet describes the division of the sensory root proximal to the ganglion. He uses local anaesthesia when opening the skull, and a general anaesthetic for the main part of the operation. He employs a special retractor, to which an electric light is attached. For tumours of the floor of the mouth Pauchet performs the radical operation from the neck, and does not hesitate to open the buccal cavity; he divides the external carotid artery during dissection of the neck. A diverticulum of the oesophagus in two stages he removes with a preliminary gastrectomy. In biliary surgery a plastic operation is described for reconstructing the common duct. A rubber tube is used to connect the stump of the common duct to the duodenum, omentum being grafted round it. Gastric and duodenal surgery has been discussed previously, but in the present volume the subject of suturing receives special consideration in association with the methods of anastomosis used in various types of gastric resections. Surgery of the colon, which was also previously dealt with, receives further attention. The author's method of reinforcing the parietes in the treatment of a large inguinal hernia by suturing a flap of the rectus sheath to Poupart's ligament is described. Abdominal hysterectomy is advised when there is suppuration of the uterine adnexa.

Vol. VI, which concludes the work, deals with a variety of subjects in a series of short articles. In discussing anal fistula and carcinoma of the distal colon, Pauchet acknowledges his indebtedness to a visit to St. Mark's Hospital, London. He advocates temporary caecostomy where any obstruction exists in the colon; this operation is followed at a later date by resection with an end-to-end anastomosis strengthened by an omental graft. For the operative treatment of gastropotosis Pauchet suggests a new procedure. He detaches the round ligament from the umbilicus, sutures it to the anterior wall of the stomach along the lesser curvature, and embeds it in the stomach wall; the free end of the ligament is then threaded through one of the left intercostal spaces and fixed there. In cases diagnosed as gastric or duodenal ulcer with marked pain, but where no organic lesion can be found, Pauchet

describes an operation practised by Latarjet, in which the vagal and sympathetic fibres to the stomach are divided, but thinks that more investigation is required before coming to a final conclusion about this operation.

These six volumes will form a useful addition to the library of an operating surgeon; the considerable amount of new work they contain provides food for reflection. There are many hints on technique, and the admirable series of illustrations makes it possible to visualize the details of each operation.

GUY'S HOSPITAL REPORTS.

THE nine articles in the first quarterly instalment of the seventy-sixth volume of the *Guy's Hospital Reports*⁵ provide a varied fare for the reader, for they include papers on medical biography, anaesthetics, physiology, morbid anatomy, radiology, dentistry, surgery, and three on medicine. Sir William Hale-White writes in his accustomed kindly and interesting style an account of Golding Bird (1814-54), who was assistant physician to Guy's Hospital (1843-54) and did so much in so short a life, both in medical literature and as a teacher at the hospital. Dr. J. A. Ryle describes five cases of erythraemia, in three of which there were symptoms suggesting a peptic ulcer—a rare occurrence in this disease. One of the patients benefited from the administration of phenylhydrazine hydrochloride, but in the article in this number on some cases from "Clinical" (series iii), by various writers, another case is recorded in which this treatment failed. The other ten cases in this interesting collection of cases from "Clinical" are mainly examples of grave anaemia with unusual features. Dr. A. J. Kohiyar brings Dr. J. R. Bell's summary of 425 consecutive cases in which fractional gastric analyses were done up to the imposing total of 1,080 by the addition of 655 analyses carried out at the New Lodge Clinic. Mr. P. J. Briggs, radiologist to the New Lodge Clinic, contributes a note on the radiological examination of the pelvic caecum and appendix, the pelvic caecum being present in 30 per cent. of normal adults. In a well illustrated contribution Major J. B. Hance records a case of myeloma of the lower third of the ulna treated by curettage and autogenous grafting from the patient's ilium, according to the method practised by Mr. A. H. Todd, who has supplied an account of two of his cases thus treated. In a clinico-pathological article Dr. W. Gordon Sear reviews congenital cystic disease of the kidneys and liver, and records such a case with, in addition, small cysts in the pancreas; the like of which he has not found in the literature. Apnoea, dyspnoea, and cyanosis in relation to anaesthesia form the subject of a paper in two parts—the physiology of the subject being set out by Professor M. S. Pembrey and the anaesthetist's point of view presented by Dr. F. E. Shipway. In an interesting account of dental education in the United States and Canada, Mr. J. Lewin Payne shows how much the position there differs from that in this country. There dentistry is regarded as a highly mechanical but not accredited part of medicine, and a medical man may not lawfully practise on the teeth, with the exception that in a few States he may do extractions. The Baltimore College of Dental Surgery, established in 1839 in the face of medical opposition, is said to be the senior dental school in the world. In conclusion, the editor, Dr. A. F. HURST, of whose activity there is as usual much internal evidence, must be congratulated on the continued success of these *Reports*.

THE TRAINING OF THE R.A.M.C.

THE immense importance of the creation of a unified Royal Army Medical Corps, and of a general staff with a graduated and systematic scheme of military training, was reflected in 1911 by the issue of an entirely new manual of training for the Royal Army Medical Corps, which embodied the principles that had previously been laid down in the Field Service Regulations, Training and Manuals,

⁵ *Guy's Hospital Reports*, Vol. 76 (Vol. 6, fourth series), No. 1, January, 1925. Edited by Arthur F. Hurst, M.D. London: Wakley and Son (1925), Ltd. (Sd. 6s. 6d., pp. 1-126; 1 full plate, 23 figures. Annual subscription, £2 2s. for volume of four parts; single numbers, 12s. 6d. each.)

⁴ *Practical Surgery Illustrated*. By Victor Pauchet. Translated by F. R. B. Atkinson. With an introduction by Sir Charles Gordon-Watson. R.C.S. Vols. V and VI. London: E. Benn, 1925. V, pp. ix + 256, 273 figures; Vol. VI, pp. ix + 240, 200 figures. 18s. 6d. net each volume.)

of a somewhat earlier date. The 1911 manual has remained unaltered until recently, although a provisional training manual for R.A.M.C. Territorial Force cadets was issued in 1920. A new manual⁶ issued with Army Orders of 1925 now takes its place, and is a document of much interest, as it embodies practically all the lessons of the great war so far as they affect the training of the R.A.M.C. The chapters have been rearranged and the matter in most of them is entirely new, while much of the diffuse writing of the 1911 edition has been reduced to clearer statements and more concise dimensions. Thus, while the 1911 edition contained fifty-six chapters in five different parts, the new edition has fifty-nine chapters in two parts, but 383 pages instead of 453. At the same time no essential section of the military and technical training has been omitted, and much important new matter has been introduced.

Military training, which forms Part A of the manual, contains six sections, dealing respectively with general training, drills and exercises, chemical warfare, medical services in the field, voluntary aid, and the Geneva Convention. The section on chemical warfare is entirely new, and provides a very full and interesting account of medical organization in chemical warfare, the defensive measures against chemical weapons, and the disposal of gas casualties, with plans of methods for protecting dug-outs and details of a gas casualty centre. The section on medical services in the field is equally interesting, for it contains all that was learnt during the war in connexion with administration, the handling and functions of the various medical units, and the evacuation and transport of wounded. These two sections are admirably compiled, and form a complete and valuable exposition of the principles which must be grasped by all ranks of the R.A.M.C., as well as by everyone who is desirous of assisting and taking part in the duties of the medical services in the field. We have nothing but praise for the manner in which the subject of military training has been dealt with in this new edition of *R.A.M.C. Training*. If there is any fault to be found it is in the diagrams, with conventional signs of the formations and movements of field ambulances, for the diagram of a field ambulance in line shows in its conventional signs four captains, one lieutenant, and one quartermaster as officer personnel of the headquarters section, whereas in column of route this section has only two captains, one lieutenant, and the quartermaster. The latter, of course, is the correct officer personnel.

Part B, dealing with the technical training of warrant officers, non-commissioned officers, and privates, contains three sections—one on anatomy, physiology, and first aid, and the other two on nursing and on food and cookery respectively. For instructional purposes all these sections are excellent and comprehensive, especially the section on food and cookery, which contains tables of dietaries for officers and other ranks and a table of foods in season with times required for cooking.

All concerned in the production of this manual must be congratulated on the result of their labours. It is difficult to imagine in what way it could be improved upon, and the R.A.M.C. is fortunate in possessing a volume of instruction of this character. It is well illustrated; some of the illustrations have been reproduced from the *Medical History of the War*, but a misprint has occurred on page 5. Illustrations 105 and 106, and not 101 and 103, have been taken from the surgical volumes of that history.

NOTES ON BOOKS.

MR. LANE CRAUFORD was, it appears, an invalid who suffered for many years from disease of the spine. He amused himself by jotting down his views on many things incidental to the life of an invalid, in a spirit of cheerful optimism which is frequent in the tuberculous; and these views he has now published under the title *The Idle Hours of a Victorious Invalid*.⁷ Mr. Crauford should know something of doctors: he passed through the hands of fifty-five of them! His medical heroes are Dr. Tom Robinson and Sir Victor Horsley. To the latter he has devoted a chapter of mild anecdote and grateful encomium. Appropriately enough in an author of such experience, the longest chapter in the

book is "About Doctors." Mr. Crauford appreciates the value of personality. He advises his readers not to choose their doctor from reports of his cleverness, but for his appealing personality. General practitioners will probably be inclined to disagree with his views on visits to specialists. Patients, he says, are liable to suffer from blind faith in their local doctor. It is "cheaper in the end to go first to a specialist, if you think you may have any organic trouble that might be serious." "The important point is to go to the right sort of specialist as far as you can judge." Unfortunately, Mr. Crauford neglects to give directions for fitting the suitable specialist to the major complaint. He merely says "Find out about him." Perhaps it was on a day when he was feeling less optimistic than usual that he penned the statement "it seems that a certain situation can arise in connexion with medical amenities when it is etiquette 'that the patient should die.'" We cannot help thinking that if Mr. Crauford reads this passage again he will come to the conclusion that it is almost as indecorous as his use of the vulgarity "gent." His chapter "Concerning Nerves" is of some interest in that it sets forth the views of a layman on various forms of treatment for the condition. If, as seems probable, Mr. Crauford has been through some of these forms of treatment, there are, no doubt, good grounds for some of his criticisms. The book meanders along a gentle, for the most part platitudinous, course, whereon other invalids may while away an idle hour.

The *Dentists Register*⁸ for 1926 contains 14,199 names, representing an increase of 381 over the figures for last year. During the year 435 dentists were registered with qualifications, and 89 under the provisions of the Dentists Act, 1921. Of the total names in the 1926 edition, 6,194 (43.62 per cent.) are registered with medical, surgical, or dental qualifications, and 8,005 (56.38 per cent.) are registered under the provisions of the Dentists Acts, 1878 and 1921. Removals from the *Register* during the year numbered 546, 115 of these on evidence of death; 400 names were restored. The General Medical Council has also issued a volume⁹ containing the lists of medical and dental students registered during 1925. The medical students registered were 1,070, as compared with 1,043 in the previous year; England heads the list with 496. Registration of dental students numbered 191, as compared with 200 in 1924.

We have received from the British Drug Houses a useful little book entitled *The B.D.H. Book of A.R. Standards*. Scientists in this country before the war were very largely dependent on Germany for their supply of analytical reagents. When the war stopped this supply the Institute of Chemistry and the Society of Public Analysts performed a useful public service by drawing up specifications for purity for 88 analytical reagents. These specifications were indicated by the letters "A.R." and British manufacturing chemists undertook their preparation. The book now issued by the British Drug Houses contains specifications of purity for 158 drugs, including the 88 original substances. It should be useful to all engaged in scientific work, for it defines clearly the standards of purity attainable commercially for the common chemicals used in research, and enables the laboratory worker to know exactly what he is buying.

PREPARATIONS AND APPLIANCES.

Lacto-Dextrin.

LACTO-DEXTRIN is a white powder, with pleasant taste, consisting of 73 per cent. lactose, 25 per cent. dextrin, and 2 per cent. desiccated lemon juice. The purpose of the preparation is to encourage the growth of *Bacillus acidophilus*, which is normally present in the intestinal flora, to make it the predominant organism and thus to combat intestinal putrefactive processes. The preparation is recommended for a large variety of colonic diseases. Large doses of the preparation are essential to produce any effect. The dose presented is two to four heaped dessertspoonfuls three times a day. The makers state that their preparation is in extensive use in sanatoriums in the United States, and that its use will produce marked benefit in a few days in most cases of auto-intoxication, colitis, diarrhoea, etc. The agent for this country is Lionel Cooper, 41, Great Tower Street, E.C.3.

A Purified Aluminium Silicate.

The preparation "Sil-al" is a purified aluminium silicate prepared for medicinal use. Aluminium silicate is being used in increasing amounts as an intestinal sedative and as a detoxicating agent. The action of the drug depends on the insoluble mucosa-forming a protective layer over the gastro-intestinal mucosa. Furthermore, the powder adsorbs intestinal toxins, and thus relieves intoxication. Its advantage over kaolin lies in the fact that it is chemically pure insoluble substance, whereas kaolin may contain varying quantities of metallic or vegetable impurities. The agent for this country is Lionel Cooper, 41, Great Tower Street, E.C.3.

SATURDAY, MARCH 20TH, 1926.

NATIONAL HEALTH INSURANCE CHANGES.

THE finance of national health insurance needs its research scholar. It is a field in which far-reaching discoveries might be made by any skilled observer who was allowed free experiment. He would certainly be intrigued by the mysterious figure of the Government actuary—now emerging to forbid the touching of a thousand pounds or two lest disaster should follow, now, with but a wave of his magic wand, calling millions from the vasty deep and placing them at the disposal of a grateful Chancellor of the Exchequer. Sir Alfred Watson must be the most adroit and most accommodating of actuaries. In a report on those clauses of the Economy (Miscellaneous Provisions) Bill which relate to health insurance he admits that the scheme is over-financed and that its actuarial basis should be revised; and he estimates that a relief to the Exchequer to the extent of well over eight million pounds may safely be obtained from this source during the next three years and a similar amount in subsequent years. Yet as a signatory to the Majority Report of the Royal Commission on National Health Insurance¹ he agrees that the payment by the Exchequer of its present proportionate share of the cost of benefits and their administration must continue, apparently to reconcile the "definite recommendation that only such extensions and modifications as involve no expenditure, or can be met within the present financial resources of the scheme, should be considered as immediately practicable," with acquiescence in the continuation, or even strengthening, of the stranglehold of Approved Societies' officials on the administration and finances of health insurance. It is quite possible that the intricacies of this actuarial display may be found to justify the reduction of future Exchequer contributions, and yet allow of that immediate augmentation of the medical benefit fund which is essential as from the end of this year; and of the modest extension of the scope of that benefit recommended for the early future. It would have been more convincing, however, to have shown a greater boldness in suggesting the release of some of those millions which have been accumulated on an actuarial basis now proved to be mistaken, and which are still to be withheld from general use in the establishment of health services for the whole body of insured persons, although the Royal Commission declares those services to be urgently needed. It is characteristic of the timidity of the report of the Commission that all the more fundamental matters are described as "problems which need not be solved now but may fitly be left over," and that admitted necessities are to be provided only at some indefinitely future period, apparently out of surpluses to be accumulated at a slower rate than in the past, while the immense present balances are to be left with all their undesirable restrictions tight around them. A memorandum showing the effects of the financial proposals of the Royal Commission so far as they affect medical

benefit has been prepared for the Insurance Acts Committee, and we hope to publish it in an early issue. It contains also a note as to the effect of the Economy Bill.

No doubt some additional economies would be brought about by adoption of the unanimous suggestion of the Commission that Insurance Committees should be abolished, and of the further suggestion of the Minority Report that Approved Societies should be abolished also. It may be desirable to make clear the present position of the British Medical Association with regard to these proposals. In the first place, it has never been disputed that, on the whole, Insurance Committees have done quite well such work as fell to their lot, and that during the earlier years of the scheme they were necessary, useful, and effective bodies. Nor is it doubted that the officers and staffs of these committees have throughout performed successfully functions which are essential to the conduct of the insurance service. It is changed circumstances and developments dictated by experience, rather than any inherent failure, which have led to the prevalent opinion that these committees have outlived their usefulness, and that their functions could be transferred with advantage. It is, however, of fundamental importance properly to constitute the bodies to which, and to determine the conditions in accordance with which, this transfer of functions should take place. If these are not satisfactorily arranged it might be preferable to let the present situation, unsatisfactory as it is, still continue.

The Report of the Royal Commission really gives no help in this matter. The proposals of the British Medical Association are contained in its Memorandum of Evidence for the Royal Commission on Local Government, and these are reproduced, with but slight modification from those published in the year 1918, in the Association's pamphlet *A Ministry of Health*. It is the effective unification of health administration—not its mere co-ordination—that is aimed at. The main administrative body would be a statutory Health Committee responsible for advising the elected council of a local government area of suitable size on all health matters, with such executive powers as the council might delegate to it. On every such Health Committee there would be suitable minority representation of the medical profession as well as of other persons or bodies experienced in health matters, the majority of the committee being members of the local authority. Alongside and in close relationship with this executive authority there would be a representative Local Medical Committee, whose functions, however, would be almost wholly consultative and advisory. If this machinery were set up and these conditions secured it would be folly to break the unity of health administration by leaving the insurance service divorced from the rest under a special independent committee. The Association is of opinion that in these circumstances the work of Insurance Committees should also be transferred, though doubtless then, as now, the general arrangements for the service of medical practitioners would remain a central matter, a local supervision merely being exercised by the health authority. It may be some time before this scheme in its entirety is accepted and established, but it is unlikely that the medical profession would tolerate any system which did not contain its essential features—the representation of the practitioners on the Health Committee and the presence of an advisory Local Medical Committee for each area. On the one hand, the oncoming of an autocratic municipal or county medical service is to be avoided, and, on the other, private practitioners of all

¹ The Report of the Royal Commission (Cmd. 2586) may be obtained from H.M. Stationery Office, or through any bookseller. Price 6s. 6d. net. Summaries of the conclusions and recommendations of the Majority and Minority Reports appeared in the Supplement to the British Medical Journal of March 6th, 1925.

kinds must be brought into responsible relationship with local health administration if their outlook is to be broadened so that they have a real interest in preventive treatment.

With regard to Approved Societies, the position is not the same. It may be that many of these societies present features which are very undesirable with regard to the number, variety, and scattered residence of their members, to their form of government, and to the effectiveness of their contact with their members. It cannot be doubted that some of these features make such societies an obstacle to the proper organization and progressive development of health services. But as long as Approved Societies are confined strictly to their proper function—the distribution of cash benefits—and to such general benevolence on behalf of their members as they are able to exercise, the propriety of their continued existence for these purposes is not a question with which the medical profession is specially concerned. Opinion in the profession is, however, strongly and totally opposed to any organization or administration of medical services by Approved Societies, either directly as individual societies, or collectively or indirectly, whether in the guise of a so-called charitable institution or otherwise. Insidious attempts, or even unconscious tendencies, to bring this about need the most careful watchfulness. Further, one other point at least in the work of societies is of first importance. It is lamentable that under the present system no statistics of local sickness incidence are obtainable, and that any statistics of occupational sickness incidence are obtainable with great difficulty, and then only very partially and unreliably. On both national and international grounds this state of affairs can scarcely be allowed to continue much longer. Whatever other registers they may keep for their own purposes, so long as Approved Societies continue they should be obliged to keep registers of their members classified as nearly as possible in accordance with their area of residence and in accordance with their last known occupation. These registers would, of course, never be perfectly accurate at any given moment, but they would be of great value. Without them, on the present system, essential information for national health purposes is going to waste, and the work entailed would be a small price to be paid by Approved Societies in return for their vested interest and privileged position.

FAT-SOLUBLE VITAMINS AND DISEASE.

REFERENCE was made a few weeks ago¹ to an important paper by Professor Plimmer on the action of the water-soluble vitamin B, and it was then pointed out that vitamin investigation had passed from the qualitative to the quantitative stage. A few years ago research on the effects of vitamin lack consisted in determining whether or no laboratory animals could survive for a few weeks on a given diet. To-day attention is centred on the problems of the quantity of vitamin needed to maintain an animal in perfect health and of the effects of a partial deficiency extending over a long period. Professor Plimmer's work on the partial deficiency of vitamin B gave results of great clinical interest, for he showed that the chief symptoms observed were loss of tone in the intestine with consequent constipation and auto-intoxication. These effects are, of course, some of the commonest ailments of civilized man.

In the British Medical Association Lecture with

which this issue opens Professor Mellanby has summarized present knowledge regarding the effects of partial lack of fat-soluble vitamins. This knowledge is very largely due to the work of Professor and Mrs. Mellanby. The chief conclusions are that partial deficiency in fat-soluble vitamins produces, in addition to rickets, deficient dentition and dental caries also, and a predisposition to infections, and in particular infections of the respiratory tract.

In the case of vitamin B Professor Plimmer showed that the quantity of vitamin needed to maintain health depended on the nature of the diet, and that a vitamin supply that was adequate for a spare diet became insufficient if the calorie value of the diet was raised by addition of a large amount of carbohydrates. The Mellanbys have found a similar effect in the case of the fat-soluble vitamins, for an excess of cereals in the diet intensifies the effects produced by partial deficiency in these vitamins. Mrs. Mellanby's observations on puppies, showing that deficient dentition and dental caries can be produced readily by deficiency in the antirachitic or calcifying vitamin, are well known, and so also is the evidence she has collected that a similar cause is an important factor in the production of carious teeth in children. Professor Mellanby has now brought forward evidence to show that lack of the antirachitic vitamin in the mother will produce a tendency in the offspring to develop rickets. This accords with other work previously done on vitamins, and it is certain that to prevent the disorders due to vitamin deficiency in children not only must infant dietary be considered, but also the diet of the mother during pregnancy and lactation.

Professor Mellanby has also brought forward new evidence that deficiency in the fat-soluble vitamins has an important effect in predisposing to infectious diseases of the respiratory tract. Investigations of vitamin deficiency have always been hampered by the readiness with which animals on a diet deficient in vitamin die from infections of various kinds, and the occurrence of severe ophthalmia was, indeed, one of the first symptoms to be recognized of deficiency of the fat-soluble growth-promoting factor. Professor Mellanby finds that puppies on diets deficient in this factor display an abnormal tendency to develop bronchopneumonia. He points out that it is generally agreed that chronic catarrh of the respiratory passages of children, tendency to bronchopneumonia, rickets, attacks of diarrhoea, and, later, enlarged tonsils, are intimately related. He suggests that a common predisposing cause for this series of disorders may be a partial deficiency of the fat-soluble vitamins either in the maternal or in the infant's own diet.

Professor Mellanby's work is obviously of great significance, since it suggests a cause for some of the commonest diseases of infancy. Like the work of Professor Plimmer, it emphasizes the enormous importance of a full vitamin supply for the maintenance of the general health of the community. It appears that infants in this country are particularly liable to suffer from a partial deficiency in the fat-soluble vitamins, whilst adults are most likely to suffer from a deficiency in vitamin B.

The new trend in vitamin research emphasizes the fact that we still are far from a complete knowledge of the real dietary needs of a community. Twenty years ago it was thought that the calculation of a human diet was almost as simple a matter as the calculation of the fuel requirements of an engine, but to-day it is clearly seen that a large number of essential needs must be considered. The first enlargement of our knowledge came from the discovery that there

¹ BRITISH MEDICAL JOURNAL, February 6th, 1926, p. 250.

were a certain number of factors the complete lack of which produced fulminating effects in a few days or weeks; starting from this, some of the effects of partial deficiency of these substances have been established. It is possible that there may be several other essential substances lack of which does not happen to produce such easily demonstrable effects. The problem of immediate importance, however, is to determine quantitatively the amounts of the known factors needed to maintain full health, particularly during such periods of stress as infancy, pregnancy, and lactation.

WASTE OF COAL AND LOSS OF HEALTH.

THE report of the Coal Commission points out that the three million tons of soot which it is estimated are discharged into the air annually are equal in weight to nearly three days' output of all the collieries of Great Britain. In effect, the work of over a million men for three days every year is devoted to providing the soot which pollutes our atmosphere. Liquid fuels can be obtained from coal—how many are now using a benzol mixture in cars—and if it were possible to subject to this process the bulk of the 147 million tons of coal now consumed in the raw state the greater part of our requirements for oil could be supplied from home sources. It is, then, of prime national importance that the methods of treatment of coal before burning, so as to render its combustion smokeless and to obviate the waste of valuable constituents, should be applied, not to one-fifth, as it is at present in the gas and coke oven industries, but to the whole coal supply.

By distillation of coal in gas ovens gas is obtained for lighting, heating, cooking, and power, coke for heating and power, tar and its derivatives, oil, T.N.T. explosive, dyes, and numerous valuable chemical products; and, in place of polluting the atmosphere with the acid sulphur products which come from the combustion of raw coal, ammonium sulphate is obtained—a most valuable fertilizer. In place of utilizing some 10 per cent. of the energy value of the raw coal, as is at present the case in raising steam power and producing electricity, and wasting 90 per cent., utilization of no less than 25 per cent. may be obtained through the methods of the gas industry. The present method of burning coal entails, then, the most wasteful and uneconomical use of the store of energy available to this country, on which the prosperity and sustenance of our present enormous population depends. We have no water power available for replacing coal, and the President of the Royal Society has warned us that the dream of those enormous stores of energy produced on disruption of atoms becoming available is not likely to come true. With the exhaustion of its coal supply goes, then, the power of Great Britain.

Side by side with the present waste of coal goes the enormous economic loss due to the smoke pollution of the atmosphere: a loss arising from corrosion of buildings and metals, soiling of clothes and decorations, obstruction of traffic and loss of time through fogs, loss of daylight and necessity of using artificial light, loss of health through cutting off of sunlight, loss of green food, and the dismal conditions of smoke-begrimed cities. It would not be an extravagant estimate to put the annual loss at £100,000,000. The records of ultra-violet radiation taken daily at the National Institute for Medical Research, Hampstead, at Kingsway in London, and at Peppard Common, Oxford, show that the loss of this radiation due to smoke pollution in London is from one-half to two-

thirds. The skin is cut off from the natural stimulus of ultra-violet rays by clothes, glass, and smoke, as well as by the mists and clouds of winter. Hence a loss of vigorous health and happiness which is intensified by impoverishment of milk and the already mentioned loss of green food—two great sources of vitamins—and the interference with other natural foods by the miller and the canner.

To balance these ill effects people are now being impelled to take arc-light baths, and thus try to make good the loss of sunshine. Abundant evidence has been obtained of the efficacy of light treatment. The antirachitic vitamin has been proved to be sterol activated by ultra-violet rays. The excellent effects of visible sources of radiant energy have been demonstrated this winter at the Zoological Gardens, where marmosets and iguanas have thrived under the close-up use of electric lamps in a way hitherto never observed with the use of dark heat. Man himself wants in this changeable damp climate such sources of warmth, but we should give up the use of raw coal and take to that of gas and coke, or any other smokeless fuel which may prove commercially successful. For the sake of preventive medicine and continuance of national prosperity the medical profession should strongly urge, on scientific grounds, the general adoption of smokeless fuel.

MEDICAL SOCIETY OF LONDON.

THE Medical Society of London held its 153rd anniversary dinner at the Grand Hotel on March 12th, with the President, Sir Holburt Waring, in the chair. The principal toast—that of "Prosperity to the Society"—was proposed by Sir Archibald Garrod, Regius Professor of Medicine at Oxford, who recalled that his father (Sir Alfred Garrod) had been one of its presidents and delivered the Lettsomian Lectures in the year in which he himself was born. Work was just as hard in those days, but it took longer to do. There were practically no specialists then, and the "post-graduate night school" for those who lived and worked in the Harley Street neighbourhood was the Medical Society of London. The medical life of that part of London had changed greatly, but the society, though it had moved with the times, maintained its independence and kept up its old traditions; all branches still met in common. The President, in his reply, agreed that the main reason for the existence to-day of such a society, at least in London, was the fact that it had not split up into sections. In recent years it had fostered general discussions in which all branches of the profession took part. He suggested that profitable future debates might be held on such subjects as the constitution of the General Medical Council, the relations between qualified and unqualified practice, and the revision of the *British Pharmacopoeia*. A matter that was looming up was the future home of the society, whose lease of 11, Chandos Street, had now sixteen years to run. The President mentioned also the appointment of a new secretary, Mr. Carter. Mr. V. Warren Low, in proposing the health of the visitors, said that hospitality had always been a feature of the society. The guests he named were Professor E. A. Gardner (Vice-Chancellor of the University of London), Sir StClair Thomson (President of the Royal Society of Medicine), Dr. F. G. Thomson (President of the British Medical Association), Sir David Prain, Sir D'Arcy Power, and Dr. Vincent Dickinson (Master of the Society of Apothecaries); he welcomed also the presidents of various kindred societies, and the editorial representatives of the *Lancet* and the *British Medical Journal*. The toast was responded to by Lieut.-General Sir William B. Leishman, Director-General A.M.S.; and Mr. S. R. M.

Townsend, Master of the Clothworkers' Company. Sir William Leishman spoke of the intense interest with which members of the medical branches of the services followed what was happening in the civil profession, for they realized how closely the one was bound up with the other, and the spread of specialism in general practice was a matter that concerned the services deeply. The Army Medical Service, he said, stood for the same thing as the Medical Society of London—the training of all-round men. It was difficult for a Director-General nowadays to translate into terms of practical administration the growing claims of specialism. An excellent short toast list ended with the health of the President, proposed by Dr. Eustace M. Callender (immediate Past President), who said that Sir Holburt Waring was the 103rd holder of that office. Until the middle of last century the president was elected for two years; Lettsom was thrice president for periods of two years and Clutterbuck twice, and Sims stuck to the presidency for twenty-two years. Dr. Callender referred to the appointments and offices occupied by Sir Holburt Waring, and said that notwithstanding all the claims upon his time he had done a great deal for the society.

THE ETIOLOGY OF CARDIAC DISEASE.

In his Long Fox Memorial Lecture¹ Dr. Carey F. Coombs summarizes much of the valuable work which he and his collaborators have for years carried out in Bristol on the etiology of cardiac disease. Thus he shows that disease of the heart arises, not from a single cause, but from a conspiracy of causes, and that it is not the seed alone, but the soil and the environmental conditions, such as stress and strain and exciting lesions, that matter. Rheumatic heart disease, like that due to syphilis, attacks all the tissues of the heart—in short, is a pancarditis. Histological examination has convinced him that the submiliary nodule or Aschoff's body, which he independently observed a few months after the Freiburg pathologist's discovery, is a constant feature of active cardiac rheumatism and is absent in other infections; for example, in subacute bacterial endocarditis or endocarditis lenta, usually due to the non-haemolytic *Streptococcus viridans*, the infection attacks the heart from its endocardial surface, and not, as in acute rheumatic cardiac disease, by the coronary arteries. The difference between the myocardial changes in the two diseases—multiple and widespread in the first, accidental and few in the other—is depicted in a diagram. The endocarditis of swine erysipelas, investigated with Dr. G. Hadfield, is a superficial mural infection of the endocardium with *Bacillus rhusiopathiae suis*, and in its superficial invasion resembles endocarditis lenta. The essential features of the submiliary nodules are found in all rheumatic lesions, such as the subcutaneous nodules, which are only the submiliary nodules on a large scale, and in the joints; they are correlated with infection by streptococci allied to the normal inhabitants of the alimentary tract, and it is suggested that the lymphoid tissue of the small intestine may, like the tonsil, serve as their focus. The bad effect of other bacterial toxins, such as that of pneumococcal infection, especially when long continued, is, of course, freely admitted, but the nature of the rheumatic submiliary nodule is different and quite characteristic. With regard to "the senile heart," which Dr. Carey Coombs observed in 40 per cent. of private patients as compared with 10 per cent. of hospital patients, the probability is that cardiac breakdown after 60 years of age is the fate of the sedentary worker rather than of the manual labourer. The new syndrome of thrombosis of the coronary arteries, described by American authors and by Drs. J. W.

McNee and Gibson in this country, is mentioned, and the suggestion of Professor F. R. Fraser that cardiac failure in elderly men is often the outcome of a series of coronary thromboses, only the largest of which are clinically appreciable, meets with support and approval. Dr. Carey Coombs pays a fine tribute to the memory of Dr. Long Fox, who displayed a noble humility and had the "student spirit" of ceaseless inquiry, in spite of the routine of a heavy practice.

THE LEAGUE OF NATIONS.

THE special Assembly of the League of Nations, which has been meeting to admit Germany to membership (writes our correspondent from Geneva), has done something else of which little note has been taken in the march of larger events. It has adopted a proposal to proceed with a scheme for establishing the headquarters in Geneva with an architectural style and spaciousness worthy of the position of the League. Hitherto the secretariat has been housed in what was formerly a hotel. Some of the most momentous decisions in the League's brief history have been arrived at in what was intended, not for a council chamber, but for a ballroom. The offices of the League are inadequate and unworthy. The Assembly—which is the public debating organ, and corresponds quite remarkably to the Representative Body of the British Medical Association in its constitution, functions, and relation to the Council—has met in a public hall in another part of the city, perhaps the shabbiest parliament house in the world. The Assembly decided last week to purchase a large area of ground, some 60,000 square metres in extent, bordering on the lake, and thereupon to erect an Assembly hall and secretarial buildings of a suitable character. The cost of this development, after allowing for the sum to be realized by the sale of the existing hotel, will be 13 million Swiss francs, or about £500,000 in English money. When completed it will be a very stately edifice on the outskirts of Geneva, in grounds that stretch to the new building of the International Labour Office, and it is hoped that each of its larger rooms may be furnished by one of the great nations in some distinctive way. The adhesion of Germany to the League entails a great enlargement of the League budget. The additional expenditure on the ordinary work of the secretariat consequent upon the admission of another great Power is estimated at £21,000 a year, and this does not include the necessary enlargement of the four special organizations of the League—those, namely, dealing with health, with social questions, with economics and finance, and with mandates. The enlargement of the section dealing with social questions will include machinery for supervising agreements with regard to the traffic in opium and other dangerous drugs—a task which it is considered will remain in the hands of the secretariat for many years to come. Then, again, there will have to be German representatives on the various advisory and technical committees, such as the International Health Organization, and the Board of Intellectual Co-operation, and as the travelling and maintenance expenses of such members are provided from League funds these funds will have to be increased on this account by £1,600 a year. There is also to be established in Berlin an office of the League, on the same lines as the offices already in existence in London, Paris, and Rome, whose function will be to reply to inquiries, to keep in touch with the German press, and to explain news coming from Geneva—a precaution the necessity of which has been illustrated by recent experience. At the moment of writing, however, Germany is still waiting. The present impasse may be explained—if one may revert to the parallel, a very close one, already suggested—by supposing that the Representative Body had been called into session and had then been held up while the Council tried to

¹ The Long Fox Memorial Lecture, delivered in the University of Bristol at the meeting of the Medico-Chirurgical Society on December 9th, 1925, by Carey F. Coombs, M.D., F.R.C.P.

adjust internal differences. In more than one respect professional organizations could teach political organizations, even the most powerful and comprehensive, how to conduct business with expedition and to bring matters to issue.

FAILURE OF SYMPATHECTOMY FOR ULCER.

WITH the intention of ascertaining how far the operation of sympathectomy is to be regarded as of value in the treatment of chronic ulcers of the leg, Garcia-Diaz has made an analytical study of 346 cases treated in this way by various operators, and on this basis has produced a report¹ which will be of great value to surgeons who are seeking to form an estimate of the practical value of the method. His verdict is unfavourable. The majority of the cases have already been recorded in the journals; but 32 have not hitherto been published. The former are classified into four groups: (1) chronic ulcers of the leg; (2) ulcers of the toes (trophic and circulatory); (3) ulcers of the ankle (varicose, syphilitic, perforating); and (4) ulcers not readily classified under the above headings. Of the 37 cases in the first group only 2 could be regarded as definitely cured; of the 21 cases in the second group a cure was obtained in none, and in one-fourth of them the disease was aggravated; of the 29 cases in group (3), 2 remained healed after seven months and 1 after three years. The fourth group includes 213 cases; of these the results are not recorded in 23; in 3 the disease was aggravated; in 118 the operation was a failure; in 10 the result was doubtful; in 40 cicatrization occurred but the cases were not followed up; in 18 healing was proved to have lasted for from one to twelve months, and in 1 case for two years. The results in the unpublished cases were even more unfavourable than those above mentioned; a durable result was not obtained in a single case. As deductions from his analysis the author considers that in the trophic lesions accompanying obliterative arteritis sympathectomy is either without effect or harmful, and is therefore contraindicated in these conditions; that in perforating ulcer consequent on wounds of nerves the value of the operation has been greatly exaggerated, and that the results have been very discouraging in the trophic ulcers of stumps. In chronic ulcer of the leg sympathectomy promotes cicatrization at first in about one-half of the cases; but it is doubtful whether the result is permanent. It is, however, among these cases that the most favourable effects are met with, although the operation cannot be regarded as curative. On the strength of experiments he describes he is led to believe that the effects of the operation depend on reflexes related to the sensory fibres, and not on any modification of sympathetic action; he would for this reason prefer the term "periarterial neurectomy" to the term "sympathectomy." Dr. Kobayashi, of the orthopaedic department of Kyoto University, Japan, has also published recently the results of a series of experiments in which the effects of periarterial sympathectomy are compared with those of section of the abdominal sympathetic trunk. He found that (in dogs) the increased blood flow on the operated side is much greater and persists much longer after abdominal than after periarterial sympathectomy. The effect of the latter is at its height up to four days after the operation, but on the eighth day a tendency to anaemia is already observable, and the hyperaemia thereafter steadily decreases. The duration of the hyperaemia can be somewhat prolonged by denuding greater lengths of the artery. After abdominal sympathectomy a very distinct hyperaemia is present on the operated side for 200 days or more. Three cases of ulcers of the foot are recorded—two of a neuro-pathic type and one resulting from chilblain; the former

derived no benefit from periarterial sympathectomy, the latter healed in about twenty weeks, but local antiseptic treatment was also employed. He concludes that the effect of this operation is seen in the course of one week, but that later the condition gradually becomes worse. He has had no opportunity of testing the value of the abdominal operation clinically.

EDUCATION REGARDING CANCER.

RECENT correspondence in the JOURNAL has directed attention once more to the very serious need for education of the public regarding cancer,¹ and the possibilities of a cure if treatment be undertaken in the early stages. Dr. Hall-Edwards has gone so far as to state that if the public were armed with the knowledge of the disease at present at the command of the medical profession, they could, by their own efforts, reduce the death rate from cancer by 25 per cent. within a couple of years. The principle underlying this statement is being taught by cancer specialists in other countries. In the February issue of *The World's Health* there are two articles on the subject by Continental workers. In the first, Professor Winter of Königsberg, to whose untiring efforts the late Mr. C. P. Childo referred in our columns, gives some startling figures with regard to his experience during twenty-five years' work. In 1903 he made the following observations on 242 patients suffering from cancer of the uterus: (1) that 15 per cent. of the doctors who had treated these patients were to blame for the spread of the disease, either because they had neglected to make a proper examination or had resorted to unsuitable remedies; (2) that 45 per cent. of the midwives, who in Germany are often consulted by women afraid to consult doctors, were responsible for the aggravation of the cancer because they had treated the patients themselves instead of sending them to a doctor; and (3) that only 32 per cent. of the women suffering from cancer consulted doctors within the three months following the first appearance of symptoms. Many allowed over a year to elapse before consulting a doctor. Basing his plan of campaign on these facts, Professor Winter set out to educate doctors, midwives, and the women of his country by every available method. He wrote special pamphlets for medical students, had leaflets distributed to midwives, and wrote articles in the daily press or gave lectures urging women to apply for medical advice and treatment. As a result the number of neglected cases rapidly decreased. Similar methods have been followed by the Franco-Anglo-American League against Cancer, which operates in France, and an account of which appears in the same number of *The World's Health*. Its secretary, M. Le Bret, urges periodical medical examinations, especially after middle age, as the only certain method for detecting early cases of cancer. This league publishes posters and leaflets, arranges lectures, and supplies articles to newspapers. It has also instituted a system of visits by social workers to cancer patients both in hospital and in their own homes. These workers use social investigation cards, on which the nature of the disease and treatment are fully noted, so that the cards furnish valuable data to cancer research workers.

ANTE-NATAL CLINIC AT EDINBURGH.

THE managers of the Royal Maternity and Simpson Memorial Hospital have taken an important step in relation to the maternity and child welfare scheme connected with the hospital. In a building in immediate proximity to and directly connected with the hospital space has been set apart for the ante-natal clinic which has been in operation for some time. The new quarters will include a waiting room, dressing room, and a large examination room,

¹ *Etude analytique et synthétique de la sympathectomie périoritélle appliquée au traitement des ulcères chroniques des membres inférieurs.* Par Dr. Guillermo Garcia-Diaz. Paris: E. Le François. 1925. (Roy. 8vo, pp. 261: 21 figures, 4 plates. 25 fr.)

² See the JOURNAL, December 12th, 1925, p. 1147, and December 19th, pp. 1197 and 1198.

and the laboratory facilities of the hospital will at all times be available in connexion with the clinic. The town council has given a grant of £1,000 towards the equipment of the clinic, which is expected to be ready for work early in April. It will be recollected by those who are interested in the matter that the late Dr. J. W. Ballantyne was one of the earliest members of the medical profession to make the problem of pre-maternity conditions his special study. It is fitting, therefore, that a memorial tablet to Dr. Ballantyne should be placed in this clinic, as the managers of the Maternity Hospital propose to do. Dr. Ballantyne first drew the attention of the profession through the pages of the *BRITISH MEDICAL JOURNAL* in 1901 to the desirability of setting aside beds in maternity hospitals for the residential treatment of expectant mothers suffering from one or other of the maladies of pregnancy, or in regard to whom there was grave fear that the infant would not be born alive. As an almost immediate result, a sum of money was given to the Edinburgh Royal Maternity Hospital to endow one pre-maternity bed, which was put in service in November, 1901. At the present time fifteen beds are always available in connexion with the ante-natal clinic for this purpose, while three or four more can be utilized if needed. From the time of Dr. Ballantyne's first proposal the supervision of expectant mothers has been regarded by the managers of the Royal Maternity Hospital as an important aspect of the hospital's work, and has gradually been adopted in other places, while the Scottish Board of Health, in its memorandum of June, 1924, dealing with schemes of maternity service and child welfare, laid special stress upon the provision of ante-natal centres. It was pointed out by Dr. T. G. Nasmyth, chairman of the board of managers of the Royal Maternity Hospital, in an address last year to the Royal Sanitary Institute, that ante-natal clinics afford to the medical man the opportunity of discovering initial symptoms and applying treatment in preventing some of the most terrible catastrophes that occur in obstetric practice. This hospital is at present making an appeal to the public for funds to erect a new and enlarged building, which is considered to be urgently necessary. The commemoration of the pioneer work done by Dr. Ballantyne, as well as the connexion of the hospital with the name of Sir J. Y. Simpson, and the introduction of chloroform into obstetric practice, should be a strong incentive to the public to support this great institution, where so much important work has been already done.

DR. HERBERT JONES.

It is proposed to present a testimonial to Dr. Herbert Jones, who has been compelled by ill health, largely due to his services in the great war, to resign the appointment of medical officer of health for the Herefordshire Combined District. The Herefordshire Medical Society, which Dr. Jones was largely instrumental in resuscitating, and of which he was honorary secretary for many years, has taken the initiative in inviting subscriptions, and the response from Herefordshire will, it is believed, be generous, for his relations with the practitioners in his district have always been happy, and he has been ever ready to assist in any case of anxiety or doubt. But Dr. Jones has done a great deal of work both for the British Medical Association and for the Society of Medical Officers of Health, and it is anticipated that many outside Herefordshire will wish to contribute. He was a member of the Central Council of the British Medical Association for two terms, and also of the Public Health Committee; he was honorary secretary of the Hereford Division on two occasions, and its chairman in 1913. He was honorary secretary of the Worcester and Hereford Branch in 1904-6, and its president in 1916, and

was vice-president of the Section of Public Medicine and Industrial Diseases when the Association held its Annual Meeting at Bradford in 1924, and vice-president of the Section of State Medicine at the Annual Meeting in London in 1910. He has long been an active member of the Society of Medical Officers of Health also; he has been a member of its council from 1900 to the present time, and was its president in 1914-15. He was also acting editor of *Public Health* in 1924-25. There are few men more intimately acquainted with the intricacies of public health law and administration, and his knowledge has always been at the disposal of inquirers. The Herefordshire Medical Society is, therefore, justified in appealing to all classes of medical men for support of this testimonial to a distinguished member of the profession, whose self-sacrificing work has been of the greatest help, not only to his own district, but to the profession throughout the country. Subscriptions may be sent to Dr. John Steed, Staunton-on-Wye, Hereford, on or before April 30th.

POST-GRADUATE COURSES ON TUBERCULOSIS.

THE Joint Tuberculosis Council has organized a series of post-graduate courses on tuberculosis during 1926. It is stated that the British courses have received the approval of the Minister of Health, and will rank for grants; the question of foreign courses ranking for grants is at present under consideration by the Minister. From April 12th to 17th Professor S. Lyle Cummins will hold a course at Cardiff, and from April 19th to 24th there will be an intensive course in London at various hospitals. Sir Robert Philip will hold a course in Edinburgh from May 17th to 22nd, and Dr. S. Roodhouse Gloyne will deal with the bacteriology and pathology of tuberculosis at the City of London Hospital from May 31st to June 12th. From June 21st to 26th a course on non-pulmonary tuberculosis will be held by Sir Henry Gauvain at Alton and Hayling Island, and a study tour in Norway is being arranged for July. Mr. G. R. Girdlestone will hold a course on non-pulmonary tuberculosis at Oxford from September 23rd to 25th. Arrangements have also been made whereby individual study visits to certain tuberculosis institutions can be arranged for a week or longer. All applications and inquiries should be sent to the honorary secretary, Joint Tuberculosis Post-Graduate Courses, 19, Brunswick Square, Camberwell, S.E.5.

SIR ARTHUR KEITH, F.R.C.S., F.R.S., Conservator of the Museum of the Royal College of Surgeons of England, has been chosen by the Council of the British Association for election as president of the annual meeting of the association in Leeds next year.

THE Board of Trinity College, Dublin, has appointed Dr. T. Percy C. Kirkpatrick to be honorary lecturer in the history of medicine in the University of Dublin. Dr. Kirkpatrick holds the degrees of M.D. and Litt.D. of the university, is a Fellow and the Registrar of the Royal College of Physicians of Ireland, and a member of the Royal Irish Academy. He is the author of several well known books on the history of Irish medical institutions, including the School of Physic in Ireland, the Rotunda, and Dr. Stevens's Hospital.

THE twelfth International Congress of Physiology will be held at Stockholm from August 3rd to 6th next. Full information as to the British party which is being formed, of the routes, and of the cost, can be obtained from Dr. W. A. M. Smart, London Hospital Medical College, London, E.1.

NINETY-FOURTH ANNUAL MEETING of the British Medical Association, NOTTINGHAM, 1926.

ST. MARY'S CHURCH, NOTTINGHAM.

the neighbourhood. We publish below the third of a series of descriptive and historical notes on Nottingham and the neighbouring country; the first appeared in the JOURNAL of December 5th, 1925 (p. 1081), and the second on January 23rd, 1926 (p. 158).

THE COUNTRY ROUND NOTTINGHAM.

BY

E. L. GUILFORD, M.A.

I SHOULD not like to say how often I have heard people say that there is no scenery worth looking at in the Midlands, and then the speaker has generally gone on to refer to some beauty spot which has taken his fancy. This is a very unjust judgement, and ought most assuredly to be refuted. Taking Nottingham as a centre, a traveller can find almost every type of scenery within a radius of forty miles. I said "almost" because the lofty mountain and the wide-stretched lake are absent.

In the immediate neighbourhood of Nottingham the two types of scenery most in evidence are river and woodland.

The Trent is a majestic stream, flowing in a wide course from west to east until it reaches Newark, when it turns northwards to the Humber. The Trent has always been notoriously fickle, changing its course, flooding its banks, and subject to drought. Modern improvements have checked these vagaries somewhat, but they have left their mark on the lands on its banks. Here and there above Nottingham the Trent is difficult for small boats, because the stream flows rapidly through a narrow bed—as, for instance, between Wilford and the beautiful wooded slopes of Clifton Grove. From Beeston up to Trent Weir the river is excellent for boating, and is much frequented during the summer months by picnic parties.

Below Nottingham the Trent has been taken drastically in hand and made to behave itself so that it may be fitted to deal with the transport of merchandise. There are many very picturesque reaches of the river between Nottingham and Newark, and near these will be found inns which do a roaring trade during the summer months. Below Newark the river is less known, not so much because it is less beautiful, but rather because it is less accessible to the

general traveller. The villages by the side of these reaches of the Trent are very charming, and at Littleborough, where a Roman road used to cross the river on its way from Doncaster to Lincoln, may be seen the eagle, the tidal wave which sweeps up the river in a wall of water some five feet high. Its passage is so rapid that the unwary boatman is certain to be swamped.

Nottingham is singularly fortunate in having Sherwood Forest at its very doors. Years ago the Forest came right up to the walls of the town, but recent industrial developments have caused the woodland to retreat some miles.

Trent Bridge, Nottingham.

On the road from the county town to Mansfield or to Ollerton there is still ample evidence of this old forest. It must always be remembered that the mediaeval forest consisted primarily of open moorland covered with heather and gorse, and here and there a belt of woodland. It is between Ollerton, Mansfield, Worksop, and Retford that the real woods for which Sherwood Forest is so famous are to be found. In this area, too, are the great enclosures of Welbeck, Clumber, and Thoresby.

Here is park land at its best, and there are probably few districts in England where so many noblemen's houses are to be found within such a small area. But this is not the true Sherwood Forest. To find this it is necessary to get off the beaten track, away from the main roads, or even the side roads—for these are overrun by trippers nowadays—right into the silent forest, among the oak trees and the bracken. Then may be felt the spirit of the forest; and the imaginative may even see Robin Hood and his fellows, resting in some glade, while waiting for news of some rich quarry to reach them. Such spots are best in the late hours of a summer or autumn day, and those who are fortunate

enough to visit them then will surely agree that there are few, if any, more beautiful places than Sherwood Forest.

West of Nottinghamshire lies Derbyshire, a county of singular beauty. Again the coming of the modern tripper has done much to spoil the handiwork of Nature. Matlock would be beautiful if it were not for man and his works, which, in this case, have spoiled it in catering for the populace. The lover of beauty only uses Matlock and other well known resorts as a base of operations. He gets off the beaten track into the secluded valleys where he can still enjoy himself. Of late years the road between Rowsley and Bakewell has been made hideous by the horns of motor charabanes and the raucous voices of trippers bound for Haddon Hall. Luckily, such folk have no desire to visit the many beautiful spots lying just off the beaten track. The lover of Nature must turn off the main road to Youlgreave and explore some of the valleys near by, and he will be amply rewarded for his trouble. Dovedale at its southern end has been vulgarized, but nothing could really spoil its natural beauty, and if it can be visited when there are few people about it will be acknowledged, even by those accustomed to beautiful scenery, to be one of the most delightful valleys in these islands. It is usually approached by way of Ashbourne, a very charming old market town well worth a closer study than it usually gets. The road from Ashbourne to Buxton is much used by motorists, and advisedly, for it is better than, though not so picturesque as, the more easterly route by Bakewell. In fact, the Ashbourne route is exceptionally bleak, as anyone will agree who has had to travel on it in a snowstorm.

Derbyshire is an exceptionally beautiful county. Collieries have spoiled its eastern side, but except for this it is well worth exploring. The scenery in the south varies considerably from that in the north. Here the valleys of the Trent, the Soar, the Dove, and the Derwent meet, and help to form a country of pleasant meadowland and broad prospects.

Tastes in scenery differ, as in everything else, and Derbyshire provides something for everybody. Should the visitor desire moors, he must go north to Kinder Scout, Langsett Moors, Stanage Edge, and the Rivelin Moors, where he will find, perhaps, the bleakest region in all England. In autumn these moors are ablaze with purple heather and russet bracken, a sight worth travelling many miles to see.

Lincolnshire is quite another story. It is by no means the unbroken flat land that it is often supposed to be, for there are the wolds, stretching from north to south, which, though never very lofty, are sufficiently steep to break the landscape up very pleasantly. Lincoln itself stands on a hill. It is a charming town, the magnificent cathedral standing up as a landmark for miles around. The east coast of Lincolnshire is a favourite holiday resort for visitors from the industrial centres of the Midlands. The popular towns are few. In the north there is Cleethorpes adjoining Grimsby, and then follows a stretch of desolate coast until Mablethorpe is reached. A few miles further south comes Sutton-on-Sea—quite small, but provided with magnificent stretches of sands, an ideal playground for children. Were it not for the sands this coast would have little attraction, for the country just inland is singularly devoid of charm. It is pure marsh, intersected by a network of dykes. Twenty miles south of Sutton-on-Sea

comes Skegness, which has grown rapidly during the last few years, and shows signs of becoming the most progressive seaside resort on this part of the coast. South of Skegness there is no place of any size on the shores of the Wash. Here the traveller is approaching the Fen Country, the land of beautiful churches, vast potato fields, and far-stretching orchards. Here is some of the richest soil in England. The potato, bulb, and fruit industries have grown rapidly during recent years, and much capital is now invested in this part of the country. A visit to Spalding when the daffodils are in bloom is a thing never to be forgotten. Vast fields of yellow stretch apparently for miles in what would otherwise be dreary flatness. All these towns in South Lincolnshire are interesting. There is an air of extreme respectability about them, though not much sign of commercial energy.

Going westward towards Nottingham again two most interesting towns are passed. Ancaster, now a little dreamy place, is famous still for its quarries, whence came the stone from which so many of the Midland churches are built. Grantham is well known as a railway junction and an engineering centre. It has other claims to attention, for

the church possesses a spire which rivals in beauty that of its neighbour at Newark, and in the town is the Angel Hotel, one of the best survivals of a mediaeval hostelry in this country. Turning Londonwards, down the Great North Road, Stamford is soon reached; it is the most southerly town in Lincolnshire; in fact, part of it lies outside that county. It is a town of architectural interest, with its magnificent churches, its mediaeval hospital, and, on the outskirts, Burghley House. No one should miss Stamford if he can help it.

South of Nottinghamshire lies Leicestershire—the hunting county *par excellence*

—a county of sloping fields, pleasant woods, and jolly little rivers. Leicester itself is a very prosperous town. It was the site of the Roman station of Ratae situated on the Fosse Way. There are some traces of its Roman origin, but Leicester's appeal to the antiquary lies rather in its old churches, which are full of problems and puzzles, which delight the true archaeologist. Loughborough has little to attract the visitor, though it is a very prosperous little place. Lutterworth, to the south of Leicester, has its close association with Wycliffe, who spent the evening of his varied life in charge of the church here, and whose ashes were strewn in the river which flows sleepily through the town. Charnwood Forest is quite the beauty spot of the county, a vast moorland tract of hilly country, beautiful yet bleak, and bravely trying to beat back the encroaching hands of industrialism.

The chief impression a visitor to Leicestershire gets is that of a county of large country houses and parks, pleasing to the eye. Some of the old houses are charming, and a stroll through such a valley as that of the Wreke is restful and typical of agricultural England. On the Nottinghamshire borders is Belvoir Castle, the seat of the Duke of Rutland. This modern building on the site of a mediaeval priory stands on the top of a richly wooded hill, and is a landmark for miles around. It gives its name to the Vale which is famous for its barley and its hunting. It is full of beauty spots which delight the eye of the artist.

This completes the survey of the district round Nottingham. Whosoever does not find something in it to satisfy his

A view in Sherwood Forest.

most fastidious tastes must indeed be exacting. It does not compare with the Lake district; it has none of the beauties of the sea coast of Devon and Cornwall; but apart from this there are spots which can compare with any others which England can show. Lincoln and Southwell Minsters have architecture which will outrival any in this country—or in any other. Southwell is a little retired town well off the beaten track, but it is well worth the trouble of getting there to visit the magnificent Chapter House, which is decorated with sculpture such as no other

building in these islands can show. Southwell, too, has interesting associations with King Charles I, as was pointed out in the last article.

What, then, are the general impressions to be got from a visit to the Midlands? A country reminiscent of all parts of England; it borders the extreme types to be found in the north, south, east, and west, and it is no exaggeration to say, that within this area, of which Nottingham is the centre, a more varied selection of scenery can be found than anywhere else in these islands.

THE LISTER WARD AT GLASGOW.

We publish a reproduction of a recent etching by Mr. Wilfred Applebey, showing the process of demolition of the Lister Ward in Glasgow Royal Infirmary. The etching has been purchased by the Glasgow Corporation for the Art Gallery collection; it shows the block of the Royal Infirmary

which used to stand on the left of the entrance gate. The ward on the lower story is that which is specially associated with the name of Lister, and of which he was in charge during his Glasgow period from 1862 to 1869. Behind the partially demolished building appears the cupola of one of the new blocks of the infirmary. The buildings have been in process of reconstruction since some years before the war, and it had been planned to utilize the place occupied by the Lister block for a new out-patient department. No great interest had for some years been taken in this block, which was one of the newer portions of the old infirmary, until the proposal for its demolition was made public some two years ago. In the half-century which had elapsed since Lister left it, many internal changes had naturally taken place and very few of the furnishings and fittings, indeed little but the walls, dated back to 1869. The managers of the Royal Infirmary were confronted by the problem that the block stood on the site which had been allotted for the new out-patient department, that it formed a considerable obstruction to the light and air in the quadrangle of the institution, and that it was difficult to plan a scheme by which the ground flat of the building could be preserved while the two upper stories were removed. On the other hand, a considerable section of the public, and of the medical profession of Glasgow, were very desirous of preserving the ward, if possible, in order to form a memento of what had been one of the principal surgical achievements of the city of Glasgow. It was in this ward that Lister originated the antiseptic treatment of compound fracture in March, 1865,

by the application of pure carbolic acid, a method he published in 1867. Here also he had tried various other substances such as zinc chloride and more dilute carbolic acid, as recorded in the *BRITISH MEDICAL JOURNAL* in 1868. The ward was justly, therefore, looked upon as the birth-

place of antiseptic surgery, although more important work in this line was done by Lister during his Edinburgh period (1869-77), when he was using more dilute applications of carbolic acid and perfecting his method. Still more important work belonged to his subsequent London period, when he saw the necessity for purifying the sponges, dirty instruments, and "unclean material upon our hands or on the skin of the patient," as we find recorded in the *BRITISH MEDICAL JOURNAL* of 1893.

The ward, therefore, although it saw the birth of antiseptic surgery, was not connected with the development of its more important phases. Those who attended the meeting of the British Medical Association in Glasgow during July, 1922, will remember that a reception was held in this ward, and that considerable disappointment was experienced because so little could be shown of the actual surroundings in which Lister had conducted his experiments and researches. When the proposal to demolish the ward was made public a considerable amount of controversy arose in the press as to whether the ward should be preserved or

DEMOLITION OF THE LISTER WARD.

(This illustration is reproduced by permission of the etcher, Mr. Wilfred C. Applebey, "Carlotia," Jordanhill, Glasgow.)

not. It was understood that the managers of the infirmary were willing that it should be allowed to stand if any person or body of persons would provide the funds necessary for the purchase of an equally suitable site for the out-patient department of the Royal Infirmary in the immediate neighbourhood. Pleas for the preservation of the ward came from the French Academy of Medicine and from various scientific and medical bodies throughout Europe and America. Sufficient success, however, did not attend the effort to raise the subscription necessary to provide an alternative site. When the demolition was in

progress, a certain number of the furnishings and fittings which had Listerian associations were secured by Mr. C. J. S. Thompson for the Wellcome Historical Medical Museum, where it is intended that they shall be exhibited when the rearrangement of this museum has been effected. The old building has now been completely removed and its place is at present vacant, but it is hoped that in the erection of the contemplated out-patient block the managers of the Royal Infirmary will include some worthy memorial of the former associations connected with the site.

Scotland.

TREATMENT OF DIABETES.

THE Scottish Board of Health has issued a circular (I.D. No. 1, 1926) to local authorities and medical officers of health reminding them that the treatment of patients suffering from diabetes may be provided by the local authorities under the Public Health (Scotland) Amendment Act, 1925, which was passed at the end of last session. Local authorities who are already supplying such treatment should inform the Board of the arrangements made in order that sanction may be obtained, and any local authority now proposing to exercise such powers should also submit its plans for approval. The Act gives covering authority for any action taken in this respect since March 1st, 1924, provided the arrangements receive sanction. Two or more local authorities may act together, if they think fit, for the purpose of the Act, but authorities wishing to combine should submit their proposals for the consideration of the Board. Arrangements have been made with the manufacturers of insulin whereby local authorities may obtain this preparation at the special rate of 2s. per 100 units, postage extra. Local authorities wishing to take advantage of this arrangement should send their orders to the Board stating the quantity and make of insulin required. The orders will be transmitted to the makers, who will supply the insulin direct to the local authority, and the Board will render accounts to these authorities in April and October.

EXTENSION OF EDINBURGH ROYAL INFIRMARY.

An agreement now seems probable between the Royal Infirmary of Edinburgh and the Edinburgh Merchant Company for the transfer to the Infirmary of the present site of George Watson's College for Boys, together with a large space of ground surrounding it, used as a playground. The education board of the Merchant Company has for some time contemplated the removal of the school to a more suitable locality. The board was prepared to accept the sum of £100,000 for the site from the Infirmary, whilst the sum offered by the Infirmary was £75,000, payable in instalments before possession; with interest this would represent somewhat over £80,000 by the time the Infirmary obtained entry. By the munificence of Sir John R. Findlay, Bt., who has offered a sum of £10,000 to the Infirmary managers for this purpose, the Infirmary has now been able to offer £90,000 for possession of the site not later than Whit-Sunday, 1931. It is believed that this will be accepted by the Merchant Company.

EDINBURGH UNIVERSITY SETTLEMENT.

The Edinburgh University Settlement, which was founded in 1905, is established in premises near the old college in a part of the city adjacent to the Flodden wall and above the Pleasance, one of the most congested districts. The Settlement is a centre of great activity, with various clubs for men and women, boys and girls, run on a self-governing basis by a committee, with the warden, Miss Grace Drysdale, as chairman. It has a membership of considerably over 500, for which the present buildings and equipment are quite inadequate. The cost of rebuilding the premises will, it is estimated, be £30,000, for which an appeal is now being made to the public. During the last week of February the students of Edinburgh University organized a carnival and other functions in an effort to raise a portion of the amount required. The interest of university students in the work of the Settlement has steadily grown, and a close co-operation exists between the

Settlement and branches of the public health authorities of the city. An occupation centre for mentally defective children, which meets daily in the Settlement, has done good work. A very useful department has been the Hospital Social Service which for some years has been carried out by ladies operating from the Settlement. Since October, 1924, this has become the Social Service Department of the Royal Infirmary.

EDINBURGH DENTAL STUDENTS' SOCIETY.

The thirty-eighth annual dinner of the Edinburgh Dental Students' Society was held on February 26th, with Mr. C. H. Kenball in the chair. Dr. John Orr, dean of the Edinburgh School of Medicine of the Royal Colleges, in proposing the toast of "The Society," said that its meetings had an effect in forming character and in teaching, which was of infinite value in professional life. Fruits of the society's influence could be seen in the type of men now being turned out. Mr. A. Scot Skirving, C.M.G., in proposing the toast of "The Dental Hospital and School," recalled the early days of the hospital as contrasted with the beginnings of the Royal College of Surgeons, which might be looked upon as parent of the Dental Hospital and School. He believed that the harder examinations were made the more candidates appeared. The higher dental diploma, which had been recently instituted, was only to be gained by persons of considerable ability, and he trusted that it would be safeguarded in every possible way, so that the holders might reasonably be proud of it. Splendid work was being done in the school, and this would be carried out under far better auspices in the new buildings which were at present under construction. Dr. William Guy, F.R.C.S., dean of the school, who replied, said that there had been a very continuous and marked advance in the status of the dental profession, with appreciation on the part of the public of the services it rendered to the community.

CHRISTIANITY AND HOSPITALS.

Professor W. Manson, D.D., preaching in Glasgow University Chapel on Hospital Sunday in aid of the Glasgow Royal Infirmary and the Western Infirmary, remarked that, although the Christian ideal seemed to have been shattered so often on the real, yet the hospitals stood out as exceptions in which there had been transformation of the ideal into actuality. Though the full social application of the spiritual ideal still remained to be achieved, yet in ministering to the physical ills of humanity the Christian experiment was almost complete. Christianity, lagging and impeded elsewhere, had in the healing of human sickness come into its own. It was possible that in the upward evolutionary process of human life the physical adjustment to the environment must precede the social and spiritual, and so man's physical sympathies had been the first to approach perfection. It might, therefore, be hoped that what Christianity had achieved in the physical sphere it would also succeed in doing in the social and spiritual spheres.

England and Wales.

THE WELSH NATIONAL MEDICAL SCHOOL.

THE conference between those in favour of the constitution of the Welsh National Medical School as an independent school of the university and those opposed to it, which, as already reported, was held in Cardiff on January 15th, appeared to come to an end without having achieved any agreement on several fundamental points. Negotiations have, however, been going on, and at a special meeting of the Court of Governors of the University College, held last week under the chairmanship of Sir David R. Llewellyn, a resolution was adopted which is considered to be a step on the road to agreement. The resolution, which was in the following terms, proposed to appoint a warden or provost to be the chief administrator and academic officer of the school:

That without prejudice to the ultimate organization of the Welsh National School of Medicine, and in particular to the future position of anatomy and physiology as departments of the College, it is advisable that immediate steps be taken to

create the office of provost or warden or master of the Welsh National School of Medicine, who shall, subject to other constitutional offices created by the charter, be the chief administrative and academic officer of the school, and who, by virtue of his office, shall act as chairman of the Faculty of Medicine and as an *ex officio* member of the Board of Medicine, and who, pending such constitutional development as may be made, shall be responsible for the performance of his duties to the College Council.

An amendment to postpone the consideration of the proposal was moved, but was opposed by Principal Trow, and was eventually defeated by 45 votes to 30. The resolution will accordingly be submitted for discussion to a conference of representatives of the College and of the University Council which is to be held next week.

MIDDLESEX HOSPITAL.

Prince and Princess Arthur of Connaught and other members of the Royal Family attended a "scientific evening" at the Middlesex Hospital on March 10th, at which about 2,000 guests were present. An extensive exhibition was arranged on the ground floor of the hospital and divided into six sections to illustrate the scientific side of the prevention and treatment of disease. One outstanding feature was a collection of different kinds of heliotherapeutic appliances in operation, showing the rapid advance of this form of treatment and its wide field of utility. Numerous firms collaborated in this section, which remained open until March 16th for inspection by medical officers of health and other medical practitioners interested. Other rooms were devoted to the curative and diagnostic procedures associated with diathermy, radium, and x rays, while a collection of pictures and various forms of surgical instruments and apparatus was lent by the Wellcome Historical Museum to illustrate phases in the history of medicine and surgery. A great variety of physiological, anatomical, and chemical demonstrations were provided in other sections, and several rooms were required for pathology, special attention being devoted to bacterial diagnosis, spectroscopy, insulin treatment, biochemistry, tissue growth, and ultramicroscopy. During the evening the new cinematograph propaganda film of the hospital was exhibited, and demonstrations were given to illustrate the properties of liquid air.

ROYAL SOUTHERN HOSPITAL, LIVERPOOL.

The annual meeting of this institution took place in the Town Hall, Liverpool, on March 8th. The Lord Mayor was in the chair, and expressed the hope that during his tenure of office the scheme to alleviate the financial distress of the voluntary hospitals and to place them in a position of security would come to fruition. The financial statement shows that the hospital is in debt to the extent of £26,414. The work of the hospital is steadily increasing, and the expense of conducting the various departments now fully equipped does not diminish. The president of the hospital expressed his view that if the financial position did not materially improve curtailment of its beneficent work would have to be seriously considered. The honorary treasurer made a forcible appeal through the local press. He said it was deplorable in view of the large population of the city that the subscription list was such a paltry one.

ENCEPHALITIS LETHARGICA.

Arrangements are in force for the reception in one London county mental hospital—West Park Hospital, Epsom—of London patients certified under the Lunacy Acts for detention in a mental hospital who are suffering from the after-effects of encephalitis lethargica, or are known to have suffered from the disease, so that they may benefit from a scheme for co-ordinated treatment and research which has been instituted there and at the laboratory of Maudsley Hospital. It has also been agreed, at the instance of the Board of Control, to receive at the same hospital not more than thirty patients suffering from the after-effects of encephalitis lethargica who are chargeable to parishes and unions outside the county of London.

L.C.C. FEE FOR MEDICAL CERTIFICATES.

The London County Council is raising its fee paid to medical practitioners, whether its own district medical officers or not, in respect of medical certificates issued

to the operative staff employed at main drainage stations and on sludge vessels. The fee, when a visit to the home of the employee is involved, has hitherto been 3s. for a certificate; it is now to be increased temporarily to 3s. 6d., and later it will be on the permanent basis of 5s. for each certificate.

Correspondence.

DYSENTERY IN MESOPOTAMIA.

SIR,—Dr. Boney (February 13th, p. 303) and Dr. Mitchell (March 6th, p. 449) express great surprise at the recent report on the health of the army with reference to the prevalent types of dysentery in Mesopotamia. Personally I see no cause for such surprise.

From June, 1917, to January, 1920, I was in charge of the dysentery wards of 133 British General Hospital at Kut-el-Amara (under Lieut.-Colonel J. G. Foster, to whom I am indebted for permission to publish these figures). From March to December, 1918, a ward register was kept in which all direct admissions of cases of dysentery were entered. Amongst the cases transferred from other hospitals higher up the line bacillary dysentery was common enough, but the register was only meant to include cases of the disease contracted locally.

All cases presenting the clinical symptoms of blood and mucus in the motions were entered as "clinical dysentery." Stool examinations were then carried out with the following results:

March to December, 1918.			
All dysentery—"Clinical"	149
Bacteriological diagnosis:			
<i>E. histolytica</i>	141
Entamoeba-free	6
<i>B. dysenteriae</i>	Nil
No organism	2

Personally I did none of the bacteriological work, but I know that *E. histolytica* was only reported to be present when (1) either the amoeba was seen in an active condition, containing red blood corpuscles, or (2) the characteristic tetragenous cyst was present.

All the other hospitals in Mesopotamia, I am aware, obtained quite different results, but probably the conditions at Kut in 1918 most nearly resembled the conditions present in Mesopotamia now.

The explanation may be as follows. Defective sanitation generally, including water supply, is the chief etiological factor in bacillary dysentery, while the presence of house-flies is the chief factor in spreading amoebic dysentery. At Kut in 1918 the general conditions and water supply were very good, the mosquito almost absent, and even sandflies reduced in number. The house-fly, however, continued to flourish in spite of miles of wire gauze round, kitchens and mess-rooms.

Probably the army in Mesopotamia enjoys good general sanitation now, but has not yet defeated the house-fly, and consequently it is not "incredible," but as would be expected, that the prevalent type of dysentery is now amoebic and not bacillary.—I am, etc.,

Tadworth, March 9th.

B. E. JERWOOD, M.D.

MENTAL IRRITABILITY AND BREAKDOWN IN THE TROPICS.

SIR,—I am interested in the letter of the Bishop of Singapore published in your issue of March 13th (p. 503) on mental irritability and breakdown in the tropics.

In the *Proceedings of the Royal Society of Medicine*, 1925, vol. xviii (Section of Tropical Diseases and Parasitology), I drew attention to the experience that fatigue, ill health, and worry bring out latent defects in the eye in any country. A hot climate causes greater fatigue than a temperate one, and this fatigue in many cases leads to fatigue indigestion, with resulting physical depression. Worry, whether of private or official origin, similarly causes ill health.

Under any of these conditions trifling errors of refraction or slight degrees of heterophoria (lack of normal muscular balance of the eyes) exert effects quite out of proportion to

their severity. It is therefore of the greatest importance that correction of these errors should be made as carefully as possible, and that the spectacles ordered should be adjusted correctly. In a highly sensitive person, whose nerves are constantly being jarred by physical or mental discomforts, the correction of a very small degree of astigmatism may make all the difference between happiness and misery.

The symptoms which patients with an uncorrected error of refraction complain of are familiar to all ophthalmic surgeons—headache, neuralgia, aching of the eyes, especially after a late night, frequent frowning, indigestion, inflammation of the eyelids, and so on. Inability to see as well as other people in the dusk is a not infrequent symptom, especially when the general health is impaired.—I am, etc.,

London, W.1, March 12th

A. F. MacCALLAN.

COMMON SENSE IN RELATION TO DOUBTFUL TUBERCULOSIS.

SIR,—In acknowledging Dr. Mackey's kind reply (March 6th, p. 449) to my criticism on the question of the best way of dealing with a case of doubtful tuberculosis, I admit that there may be two schools of thought. In the earlier days of public health (tuberculosis) organization the commoner view was that held by Dr. Mackey—namely, that the doubtful case should be treated on the assumption that tuberculosis was present. But the experience since gained has convinced many that the "benefit of the doubt" lies rather in leaning to the negative than to the positive side, until a definite decision can be arrived at. I cannot help thinking that Dr. Mackey somewhat exaggerates the danger from delaying sanatorium treatment in such cases for a week or two, or sometimes even a month or two. If the patient is kept under careful observation it is improbable that the disease, if present, will make such progress that by the time a definite diagnosis can be made his chances of benefiting from sanatorium treatment will be seriously jeopardized.

The whole idea of careful observation, including sputum examinations, temperature records, weight records, and in appropriate cases tuberculin tests (from which, however, cases of haemoptysis would be excluded), is that a definite diagnosis shall be arrived at before the disease could have made any serious progress. The longer the time required to arrive at a definite diagnosis, the less the likelihood that the patient has a very active and progressive type of infection.

Dr. Chandler, in a letter published in the same issue, says he fails to understand the point of my letter, because Dr. Mackey had advised only a "restful fresh-air holiday" and not sanatorium treatment. In my letter I argued that "the restful fresh-air holiday" under careful observation, prescribed for the patient, would generally connote a period of treatment at a sanatorium. That this is accepted by Dr. Mackey himself is apparent from the final paragraph of his letter.

Dr. Chandler is very properly indignant at finding "with what equanimity some doctors will regard haemoptysis." Every tuberculosis specialist will echo his sentiment. But I, in turn, fail to see what this has to do with the point at issue. I do not advocate that haemoptysis should be neglected. On the contrary, I advocate a period of intensive observation, embracing all the "important elements" of investigation of which Dr. Chandler speaks. At the same time, with regard to cases of haemoptysis occurring without other symptoms or physical signs, and in which no subsequent development of pulmonary disease occurs, I prefer to maintain the scientific attitude of mind rather than adopt the dogmatic attitude, and, while looking upon tubercle as the most probable cause in such cases, to regard it as "unproven."

As to the outstanding importance of early diagnosis, which means early treatment, all authorities on tuberculosis are agreed. Unfortunately there are many practitioners who are not so fully alive to this.—I am, etc.,

Alderley Edge, Cheshire, March 8th.

E. WEATHERHEAD.

P.S.—The Editor has kindly allowed me to add a few words with reference to the letter from Dr. Bushnell which

appeared in the last issue of the BRITISH MEDICAL JOURNAL. Dr. Bushnell has started a different hare. I cannot agree with him that there is any appreciable risk of infection of a possibly non-tuberculous person at a well ordered sanatorium. Indeed, I believe that a well ordered sanatorium is one of the last places at which one would be likely to get a massive dose of tubercle bacilli. I was concerned solely with the disastrous social consequences that may result from a mistaken diagnosis of tuberculosis. This does not mean that on general principles I am not in agreement with Dr. Bushnell that suspects under observation at a sanatorium should preferably be accommodated in separate "observation sections."—E. W.

March 13th.

THE THYROID AND MANGANESE TREATMENT.

A Warning.

SIR,—In an interim report on this treatment published in the JOURNAL of December 26th last (p. 1209) I described a cachet containing pure potassium permanganate gr. 1/8 in powdered form, combined with a powdered thyroid gland tablet of a grain or half-grain strength. And I stated that the tablet referred to was the "ordinary" 1-grain thyroid tablet which is prepared by the wholesale druggists, meaning a tablet which is standardized, and commonly believed to be equivalent to thyroid siccum gr. 1/5.

But apparently my meaning has not been understood, for chemists and wholesale druggists have been combining these drugs in very irregular proportions. I have two samples in front of me which come from well known houses. One is a combination of potassium permanganate gr. 1/8 with thyroid siccum gr. 1. This contains five times more thyroid substance than I suggested; yet it has been sent to me as representing such.

The other is a combination of potassium permanganate gr. 1 with thyroid siccum gr. 2. This contains eight times more permanganate and ten times more thyroid siccum than the cachet described as having properties of considerable promise. Doses such as these may be found useful on rare occasions, but from the experience gained by watching the effects of various strengths of the drugs I should regard them as likely to be harmful if frequently repeated. I have felt compelled to draw attention to this matter in case the mistake is made by other makers, for the more one uses this combination the more one realizes that the smaller dose of thyroid is the more generally useful.

This is not the time or place to enter into speculations as to the underlying reasons why interesting results are being seen by combining these two drugs in cachet form; but this at least can be said, that whether any new product is formed or not when these drugs are loosened simultaneously into water, much depends upon their being presented to the tissues in that fluid medium.

This being so, no soluble container should be used in making them which, when it is filled with the powder, sinks in water. The solution's power evidently depends upon it being freshly made in the empty stomach, and in that form passing quickly into the bowel; whereas if the container were to sink to the bottom of the half-pint of water with which it is swallowed it might easily pass through the pylorus unopened.

Another matter of practical importance must be touched upon—that is, the type of cachet holder that is used in making this cachet. The best one by far is the telescopic type, where the cover slips over the holder fitting so tightly that no moisture need be used to make the two parts adhere.—I am, etc.,

HERBERT W. NOTT.

Little Sutton, Feb. 27th.

DIET IN NURSING HOMES.

SIR,—In numerous English nursing homes the diet is excellent, but in others the reverse. I cannot state in what proportion of nursing homes the diet is unsatisfactory, since a reliable estimate could only be given as the result of prolonged investigations. But, from my own limited experience, I feel justified in concluding that the number of nursing homes in which the diet is unsatisfactory is so large as to make it desirable, in the interests of patients,

that the attention of medical men should be directed to the subject. Whilst I was a patient in an expensive London nursing home my diet was very often unsatisfactory. My wife was a patient in a well known and expensive London nursing home, and the end of her life was rendered miserable by the bad food. Many friends (chiefly relatives of medical men) who have been treated in expensive nursing homes have given me their opinions as to the diet in these homes; almost always it has been declared to have been unsatisfactory. During my practice as a consulting physician for thirty-six years in a large provincial town, I had many patients and friends who were treated in the nursing homes of that town; and when I had the opportunity of obtaining their opinions as to the diet, almost always it was declared to have been unsatisfactory. I know from my own experience that the dieting of patients in private nursing homes is frequently left by medical men entirely in the hands of the cook. Consequently unsuitable food is often supplied. Others may not have had such bad experience, but I cannot think my own is exceptional. Patients in many nursing homes have a right to expect more satisfactory food, both as regards quality and quantity. I would urge all medical men who are treating patients in nursing homes to see that their diet is always sufficient, and satisfactory as regards both quality and cooking.—I am, etc.,

March 8th.

PHYSICIAN.

FINAL NURSING EXAMINATION.

SIR,—Sister Tutor Billinghamurst, in her letter (JOURNAL, March 13th, p. 506), suggests that it is wise that nurses should be trained to recognize the early symptoms of disease, because when acting as private or district nurses they may be consulted as to the significance of these symptoms, or may call attention to their importance and the need for medical advice.

I readily admit that a nurse may have many opportunities for this, but I am not ready to admit that it is a necessary part of the work of a nurse, or that she need be trained for it. Whenever she is consulted on such a matter I submit that the advice she should invariably give is that a doctor should be consulted; and I think she should explain to those asking her advice that she has been trained to nurse the sick, and not to act as an unqualified medical adviser to the public. There is a very unfortunate tendency among the public to consult nurses as if they were doctors, and this should be most definitely discountenanced by all nurses. It is an attempt to get advice with little trouble, and no expense, in the same way that they apply to chemists for advice and treatment. The nurse, when consulted in this way, should invariably be the signpost directing to the doctor, and nothing more. If, with the smattering of medical knowledge which she may have acquired, she takes on herself the responsibility of saying, "Oh no; that is quite a trifling thing, and you need not trouble your doctor about it; make your mind quite easy," she may be right now and then, and quite wrong at other times. For instance, she may tell one woman who has slight haemorrhage after a well established menopause that it is of no consequence as long as it does not make her ill, or another woman that a lump in her breast need not be the cause of any anxiety because she knows of a case where an exactly similar lump disappeared. But, of course, even though she may have the most imperfect knowledge of medicine and surgery, she may know just enough to call attention to some symptom or sign of really serious disease, when her advice is not sought, and therefore it might be advisable to give to all nurses, instead of the useless courses in medicine and surgery they now attend, a course of lectures on the indications for calling in the doctor, which might be almost as useful to her as a course of first aid; but I think the better way would be to issue a guide direct to the public. A small book might with advantage be published, and sold at a very small price, on when to consult the doctor, or early signs of serious disease, written, not by a nurse, but by the collaboration of medical and surgical specialists. Such a book would emphasize the importance of recognizing such things as the danger of neglecting a lump

in the breast, an ulcer on the tongue, or the attack of severe abdominal pain and vomiting, which might be the early stage of acute appendicitis, or other abdominal emergency. The distribution of such a book free to the poor by the municipal health authority would be a very great advantage.

The other reason given by Sister Tutor Billinghamurst why nurses should be instructed in, and examined on, the surgical treatment of disease is that they may be able to make preparation for it—have everything ready for the surgeon to treat retroversion of the uterus, for instance. But surely the nurse need not know how to treat the case for this. All she need know (and be asked at the examination) is what she would have to prepare for the particular treatment which was going to be adopted. It would be ridiculous to ask a nurse, in an examination, how to remove the appendix, but it would be quite a proper question to ask her how she would prepare the patient and the operating theatre for an abdominal operation.

I am not a gynaecologist, but it seems to me that to "help a woman in the matter of attention to pessaries" does not require any knowledge of retroversion of the uterus, and that if it is a matter requiring more than a knowledge of simple gynaecological nursing it is one for the doctor, and not for the nurse.

Sister Tutor Billinghamurst points out that in the nursing examination alternative questions are given, "so that if a nurse finds one question which she cannot answer she can leave it for another." But what guarantee have we that both questions may not be as absurd, and unfair to the nurse, as those given in the examination paper which is the subject of this correspondence?—I am, etc.,

Bristol, March 14th.

CHARLES A. MORTON.

** Owing to the heavy claims upon our correspondence columns we are unable to find space for a number of other letters on this subject.

PHTHISIS A DISAPPEARING DISEASE?

SIR,—We are indebted to Dr. Baskett (March 6th, p. 449) for his insistence on the dependence of tuberculosis mortality on national poverty, but I should like to suggest a fallacy in his criticism of Dr. Flemming's reference to phthisis as one of the disappearing diseases. The fallacy consists in the appraising of rate of decline by actual decrement, instead of the ratio of this decrement to the diminishing death rate; an inch means much more to the Nelson Monument than to Mount Everest. This source of error has been fully described by Sir Arthur Newsholme in his book on vital statistics, with reference to this very subject of tuberculosis.

Dr. Baskett's statement is that the decline in phthisis mortality between 1896 and the present day is not nearly half so fast as before 1896. From the Registrar-General's review for 1924 (p. 35) it can be ascertained that the death rate per million from respiratory tuberculosis was, in the lustrum 1838-42, 3,782; in 1891-95, 1,461; and the mean rate over the five years 1920 to 1924, 865. It is a simple matter to find, by the aid of logarithms, that the rate of decline in the death rate was, in the fifty-three years between the first two lustra, 1.78 per cent. per annum, and, in the twenty-nine years between the last two lustra, 1.79 per cent. per annum. It would appear, therefore, that the decline has operated at a surprisingly constant rate, but fractionally faster after 1895 than before.—I am, etc.,

Guisborough, March 8th.

C. R. GINSON.

THE ACTION OF CERTAIN ALLEGED INTESTINAL ANTISEPTICS.

SIR,—In an article appearing in the JOURNAL of February 27th (p. 367), entitled "On the action of certain alleged intestinal antiseptics," Dr. Lawrence Garrod mentions one of our products, *izal* perles. We trust we may be permitted a few remarks on the deduction drawn.

Dr. Garrod rightly emphasized the difficulties of forming any accurate estimation of "the action of an alleged intestinal antiseptic . . . on the organisms in the upper part of the intestinal tract," and "to enumerate living

anaerobes [in the faeces] with accuracy is almost impossible." "Wide variations may occur from day to day in the total numbers of living organisms in the faeces."

It is of interest to note that Dr. Garrod's results with izal (1922) confirm the work of Gordon done twenty years ago, and that izal is the exception referred to. We are sorry Dr. Garrod did not feel disposed to invite our assistance in his investigation. Since we maintain a large permanent staff of qualified chemists, we could have confirmed that the composition of the oil in izal perles—a refined fraction of polymethyl phenols having the physical and chemical characteristics of isopropyl-meta cresol (thymol)—is guaranteed to be in every respect equal in germicidal value and quality to the oil always used for izal perles.

We do not admit any obligation "that specific and detailed evidence as to the alleged action of these drugs should be published," seeing that, apart from publishing Gordon's investigations years ago, we have never spent one penny in advertising izal perles.

The extensive use of this product by physicians and their constant recommendation of it is in these circumstances surely proof of value, especially when such use has continued to grow without the aid of advertising over a period of twenty-five years.

Dr. Garrod, unfortunately, does not indicate if keratin-coated perles were used for his experiment.—We are, etc.,
NEWTON, CHAMBERS AND CO., LTD.

Thorncliffe, near Sheffield, March 11th.

** With regard to the above reference to Dr. Mervyn Gordon, we are informed by Dr. Gordon that having found experimentally that izal oil, when taken by mouth, was capable of reducing very considerably the number of organisms in the faeces, he published a paper in the *Lancet* in 1902 giving details of the experiments and their results. We are further informed that, without consulting Dr. Gordon, Messrs. Newton, Chambers and Co. circulated a reprint of his paper. Dr. Gordon requested the firm to discontinue this, and understands that they ceased to do so.

** We have received the following correction from Dimol Laboratories of their letter published last week (p. 505):

"A slight confusion would appear to have been introduced by the use of the word 'solution' in regard to the behaviour of a dimol tablet (after removing the outer coating) in water. Whether it is 'dissolved' in 20 c.cm. of water or in 200 c.cm., the result is the same—not 'solution' in its strictest sense, but an extremely fine emulsion, which is conventionally termed 'solution,' even by bacteriologists. Dimol is made available in this form for the simple reason that, other things being equal, emulsions of bactericides have at least three times the efficiency of solutions."

ARTIFICIAL LIGHT CLINICS IN GLASGOW.

SIR,—In your notice of the Glasgow public health department's report on artificial light treatment, in the *JOURNAL* of March 13th (p. 494), you say that mercury vapour lamps of 20 to 75 amperes are being employed. This is of course an error. The 20 and 75 ampere lamps are open carbon arcs, after the style of those used by Reyn at the Finsen Institute. We also use a mercury vapour lamp, but it is of the ordinary K.B.B. type.

I shall be pleased if you will make the necessary correction.—I am, etc.,

Glasgow, March 15th.

ALEXANDER SMITH, M.B.

** We regret the error, which would give a wrong impression of the dosage with mercury vapour lamps. Such a dosage as was erroneously mentioned, with such a lamp, might cause serious trouble.

The Services.

INSPECTOR-GENERAL H. C. WOODS, C.B., C.V.O., M.D., R.N.(ret.), has been awarded the Greenwich Hospital pension of £100 a year, in the vacancy caused by the death of Inspector-General T. Browne, M.D., R.N.(ret.).

DEATHS IN THE SERVICES.

Surgeon Captain Alfred Ernest Weightman, O.B.E., R.N.(ret.), died in London on February 6th, aged 66. He was educated at Queen's College, Galway, and at Liverpool, and took the L.R.C.P. and S.D. in 1884. Entering the navy soon after, he reached an honorary step as surgeon captain, on November 11th, 1918. He received the O.B.E. on June 3rd, 1918.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

THE House of Commons has been concerned this week chiefly with the Economy Bill, which had a second reading debate on March 16th and 17th, and also with the Civil Service Vote on Account which accompanied this measure. The Army Estimates were introduced and sanctioned on March 15th. To aid discussion on the Economy Bill the Chancellor of the Exchequer issued a White Paper analysing national expenditure.

For consideration of the Births and Deaths Registration Bill and the Midwives and Maternity Homes Bill Dr. Fremantle, Sir Richard Luce, and Sir Kingsley Wood have been added to Standing Committee A. Dr. Drummond Shiels has been substituted for Dr. Salter in the committee on the registration of nursing homes.

The Economy Bill.

On March 16th the Economy (Miscellaneous Provisions) Bill came before the House for second reading. A preliminary memorandum was issued to explain its provisions.

The memorandum states that £8,310,000 to £10,160,000 is estimated to be saved by the bill in 1926-27, chiefly in National Health Insurance and in Unemployment Insurance. In view of the fact that the surpluses of approved societies were estimated to amount to £65,000,000 at the end of last year, the bill proposed to reduce the State contribution to health insurance from two-ninths to one-seventh in the case of men and one-fifth in the case of women as from January 1st, 1926. This reduction of grant would not diminish the accumulated surpluses, of which £30,000,000 had been, or will be, allotted to additional benefits payable in 1925-31, nor would it reduce the additional benefits at present provided. The memorandum pointed out that from 1928 additional sickness and disablement benefits would not have to be provided for persons from 65 to 70, who would be in receipt of old age pensions under the Act of 1925. This would practically counterbalance the change in the State grant, so far as additional benefits based on the first and second valuations were concerned. Provision was made for meeting from the Reserve Suspense Fund any deficits in the funds of individual societies and branches which might result from the reduced State contribution. A sum of £1,100,000 was to be transferred to the Exchequer from the surplus in the Navy, Army, and Air Force Insurance Fund.

Concerning the provision for medical benefit, the memorandum said that the authorized charge for medical benefit under the National Health Insurance Act was 9s. 6d. a year for each insured person, with a further 6d. for administration. The actual cost at present (including the 6d.) was about 12s. 6d., seven-ninths of the excess being temporarily met from unclaimed stamps of the excess and other sources. This provision came to an end on December 31st, 1926, and, as recommended by the Royal Commission, it was proposed to place the full charge, not exceeding 13s. per insured person (including 6d. for administration), upon the funds from which benefits were ordinarily paid. The maximum additional charge involved was about £2,300,000 a year, towards which the Exchequer would contribute one-seventh (men) and one-fifth (women)—approximately £400,000. The latter was not a new charge; the Exchequer was already paying the statutory proportion of the whole expenditure authorized. Special provision was made to meet Scottish conditions, without, however, altering the maximum amount to be devoted to the cost of medical benefit.

Government Actuary's Report.

The Government also circulated a report from the Government actuary, who, in recommending these changes in the finance of medical benefit, explained that the rates of sickness by which the liabilities in regard to sickness and disablement benefits were assessed would be taken, in the case of men, on the basis of the rates disclosed by the experience of the Manchester Unity of Oddfellows in the five years 1893-97, due allowances being made for the commencement of sickness benefit on the fourth day of incapacity. The change from the present basis in this respect consisted in the deduction of the margin of approximately 13 per cent. originally added to the Manchester Unity rates, and which, after evidence of experience in the years 1921-23, the Actuarial Committee considered to be unnecessary. The liability for sickness and disablement benefits in women would be estimated with reference to rates of sickness deduced from the experience of a representative body of insured women in 1923. This experience was obtained by the Ministry of Health from the records of approved societies chosen in such a way as to constitute as nearly as might be a microcosm of the whole population of insured women.

Second Reading Debate.

Mr. Churchill, in moving the second reading of the bill, said that the first proposal was to reduce the State contribution to health insurance from two-ninths to one-seventh for men and one-fifth for women. This would effect a saving of over £2,750,000. The con-

tribution of the State to the Widows and Old Age Pensions Bill was £5,750,000, and the old age pension was granted at 65. This substantially reduced the liabilities for which the health insurance fund was responsible, by taking off from the beginning of 1925 every contributor between 65 and 70—that was to say, at the period of life when sickness benefits were at a maximum, and would relieve the fund of a responsibility actuarially computed at upwards of £37,000,000. The surplus of the health insurance fund was to-day estimated at £65,000,000. Of this, £13,000,000 was due to be spent over the next five years in additional benefits. The Royal Commission had reported that after providing these large additional benefits there would be a surplus of over £2,000,000 per annum after meeting also the cost of medical benefit for which this bill also made provision. Of course, it would be very agreeable to apply this surplus on still further extending the benefits, and it would be easy to unfold many desirable plans for spending the money. Such plans would, however, automatically attract an additional State grant of £500,000, and would throw an increasing burden upon the overstrained Exchequer. The Government had therefore decided that the time had come when the State contribution to national health insurance could, both in justice and in prudence, be reduced as proposed in the bill.

Mr. Snowden moved the rejection of the bill, on behalf of the Labour party. He said there was no economy in the reductions in the bill, but the intention undoubtedly was to rob the sick, the disabled, the unemployed, and the children.

In the course of the debate, Dr. Drummond Shiels discussed the National Health Insurance aspect of the bill. As had been pointed out, the scope of the National Health Insurance Bill of 1911 was very much wider than the actual scheme in operation at present. The first essential in the social health insurance system was a complete medical scheme, not only a general practitioner service, but a scheme which would give all expert advice, both medical and surgical, and all remedial and curative agencies, such as dental and optical treatment, and all kinds of institutional treatment, with skilled nursing, with the help of such accessories as x rays, massage, light treatment, and so on, which could not be given in the miserable homes in which so many of the workers lived. The original Insurance Act of 1911 did not limit the kind of medical system which might be set up. The limitation was made by Regulations under the Act, and was doubtless a result of difficulties with the medical profession, and also financial and administrative difficulties. Just before the war proposals were brought forward by the Government of that day for an extended medical service, but these had to be dropped, like many other things, on account of the war. Since then they had been hoping for and expecting the new developments of the extended medical service. The Act had proved its soundness by being able to carry on during the war. It had gone through two actuarial examinations, and was now regarded as financially sound. The Royal Commission suggested that the various medical services organized by the State would continue to expand, both in their scope and in the range of the persons to whom they applied. They said, also, that medical benefit had been a valued and successful element in the scheme of National Health Insurance, and, further, that while it had been inevitable hitherto that medical benefit should be confined to a general practitioner service, this limitation had detracted from the value of the benefit, and its removal was urgently desirable. This extension of treatment, which the Commission considered urgent, should be made, they said, if and when funds were available, in the following order: Expert medical advice and treatment for persons who could travel to meet the specialist; expert advice and treatment for persons unable to travel; and laboratory services. These recommendations were arrived at after careful investigation of the finances of the scheme, based on the present arrangement and the present ratio of payments by workers, employers, and the State. The proposals of the Government in this bill were, therefore, made in face of the findings of an impartial Royal Commission, which recommended the continuance of the health insurance service on the present system of contribution partnership, and with its present amount of State grants. The man responsible for the Government White Paper explaining the provisions—the Government actuary—was actually a member of the Commission which made this recommendation. It was, therefore, given after a full consideration of the fact that a reduction of the State grants would prevent the extension of the medical benefits which, in the opinion of the Commission, was desirable, and which was part of the original bargain made with the insured.

Mr. Neville Chamberlain, interposing, said that he was sure Dr. Drummond Shiels did not want to mislead the House. He would recollect that the report of the Royal Commission, while recommending the extension of medical benefit, pointed out, and indeed recommended, that that extension should be financed out of the surpluses. It therefore did not depend upon the continuation of the present State grant.

Dr. Shiels, continuing, said that Mr. Chamberlain would admit that the Commission never contemplated, or at least it did not express the expectation of, any reduction of the present amount paid by the State. He submitted that this so-called economy by the Government was a declaration by it that it did not realize the importance of this great health service for the workers of the country.

Army Estimates.

Sir L. Worthington-Evans, Secretary for War, introduced the Army Estimates into the House of Commons on March 15th. He said the normal system of promotion in the army up to the rank of major would not be changed, but officers of conspicuous merit would be selected for and granted accelerated promotion. All pro-

motion above the rank of major would be by selection. Recruiting had been good throughout the recruiting year ending September 26th last. The number of candidates for enlistment rejected as unsuitable on physical and medical grounds was still very high. The only real shortage of officers was in the Royal Corps of Signals and in the Royal Army Medical Corps. This shortage had nothing to do with the recent reduction in the pay of officers now entering the army.

On the question that the establishment of the army in 1926-27 be 159,400, all ranks, Sir Richard Luce said it was time the House of Commons should realize the deplorable condition to which the Royal Army Medical Corps had been driven because it was unable to obtain the necessary recruits. The establishment of officers of the R.A.M.C., which had been about 1,000 before the war, was now fixed at 900, but the strength was only 794. Between the end of the South African war and the outbreak of the great war the R.A.M.C. had developed into a really splendid body, after a long struggle against official prejudice and inertia, coupled with economy. In the great war the R.A.M.C. did what was expected of it, and its very success was its undoing. The public had forgotten it, and the "axe" had been applied until the whole tree was in danger. The present unpopularity of the corps was partly due to the fact that the increase of pay in the R.A.M.C. was less in proportion than that of any other branch of the service. A captain's pay in the R.A.M.C. had been increased by only 74 per cent., but that of a captain in a line regiment by 88 per cent.; a major's pay had been increased by 49 per cent., compared with 97 per cent. for a major in a line regiment. The increases granted in retired pay had been grossly inadequate. An officer who left the service as a major got less than he would have got before the war. Last year, owing to the report of the Lee Commission, it became necessary to increase the pay of all officers of the Indian Civil Services, especially the pay of married officers, and to give married officers of the army serving in India extra allowances. But the R.A.M.C. was specially exempted from this extra allowance, although serving in exactly the same conditions as other branches of the army in India. The result had been that, whereas 45 new recruits were required yearly to make up the wastage of the corps, it had only been able, during the past three years, to get an average of 10, and there was a yearly loss of about 35 officers. The officers of the corps were hardly able to perform the duties expected of them, much less the duties which would be expected in time of war. They could only carry on at all by employing civil practitioners (who could not be sent abroad) where R.A.M.C. officers should be employed. The shortage made the corps more unpopular, for the work was harder on those who were left. There were practically no juniors, and senior officers had to do the work of juniors. As the officers of the corps became more and more discontented, that discontent prevented fresh officers joining. Last October a committee was appointed by the Cabinet to inquire, not only into the R.A.M.C., but into the medical services of the Navy and the Air Force. That committee was still sitting. Various recommendations had been made to it for the improvement of the corps generally; first, in the matter of pay, especially those in the middle ranks, majors and lieutenant-colonels, who suffered most because their expenses were heavier; secondly, for the removal of the grievances to which he had referred; and, thirdly—this point had been pressed over and over again but had always been turned down—for the granting of a position on the Army Council to the Director-General of the Medical Service. This was one of the most important considerations. If the service was to be maintained it should have a separate voice in the control of army matters. There would be a heavy responsibility on the Government if it failed to appreciate the need for restoring this service to popularity and well-being. He knew the Secretary for War appreciated what was happening to the corps, but he appealed to the whole Government and to public opinion.

The House agreed to the vote, as also to the votes for pay, pensions, and other army services.

Coroners Bill.

In moving the second reading of the Coroners (Amendment) Bill in the House of Lords, the Lord Chancellor said the first clause required that coroners should have a professional qualification, either medical or legal, saving for persons who had served as coroners for not less than five years prior to the commencement of this Act. There was a provision abolishing the requirement that a county coroner must possess land in fee. A coroner was to be appointed for the Isle of Wight on the same footing as in the rest of the United Kingdom, and franchise coroners were to be abolished. Borough coroners, like county coroners, were to be paid by salary. A council might call on a coroner to retire upon pension. There was also a provision to enable the coroner to retire voluntarily or on medical grounds. A clause made permanent the section of the Juries Act of 1915 which enabled a coroner to dispense with a jury in certain cases, but the bill provided that a jury must be summoned if it appeared to the coroner: (a) that the deceased came to his death by murder, manslaughter, or infanticide; or (b) that the death occurred in prison or in such place or in such circumstances as to require an inquest under any Act other than the Coroners Act, 1887; or (c) that the death was caused by an accident, poisoning, or disease, notice of which is required to be given to a Government department, or to any inspector or other officer of a Government department, under or in pursuance of any Act; or (d) that the death was caused by an accident arising out of the use of a vehicle in a street or public highway; or (e) that the death occurred in circumstances the continuance or possible recurrence of which is prejudicial to the health or safety of the public or any section of the public. These, said Lord Cave, were useful

MEDICAL NOTES IN PARLIAMENT.

[THE BRITISH
MEDICAL JOURNAL]

safeguards, and would secure, in those cases in which a public inquest by a jury was especially desirable, that a jury should be called.

The bill further proposed that the viewing of the body should be obligatory only on the coroner himself. It extended the power of the coroner to accept the verdict of a majority of the jury, and also, in other cases of disagreement, to discharge the jury and begin the inquest afresh, instead of adjourning it to the assizes. Where two deaths arising from the same cause had occurred in different jurisdictions the bill would enable a body to be taken, by order, into another jurisdiction, so that only one inquest might be necessary. An inquest could be held, by direction of the Secretary of State, even when the body was destroyed or otherwise not available. A second inquest could be held where the High Court was satisfied that, by reason of the discovery of new facts or evidence, this was necessary or desirable. To avoid clashing of a coroner's inquest and an inquiry before the magistrates in cases of suspected murder, manslaughter, or infanticide the bill provided that, in the absence of reason to the contrary, the coroner should adjourn the inquest until after the criminal proceedings. Where the inquest was resumed the coroner must furnish the particulars needed for registration of the death. If it was resumed the issues decided in the criminal proceedings must not be canvassed. The bill also provided for certain *post-mortem* examinations or analyses being made without holding an inquest.

Lord Strachie said the County Councils Association welcomed the bill and approved its provisions. He thought, however, that in counties the appointment of deputy coroners and of assistant deputy coroners should rest with the county council. Deputies to medical officers of health were always appointed by the council. Lord Haldane remarked that if the bill passed a consolidation bill would thereafter be urgently required. The Lord Chancellor agreed. He did not know whether it would be possible to consolidate the Coroners Acts this year, but the suggestion would be considered.

The bill was read a second time, and the Committee stage was set down for March 18th.

Deaths in England and Wales.—In reply to Mr. Rhys Davies, Mr. Neville Chamberlain furnished the following analysis of deaths registered in England and Wales:

Year.	Total.	On Medical Certificate.	On Coroner's Certificate (Inquest Cases).	Uncertified.	
				Reported to Coroner.	Not Reported to Coroner.
1896	526,727	482,109	32,990	11,628	2,034
1900	587,330	539,712	36,861	9,223	617
1910	483,247	441,480	35,109	6,041	—
1920	466,130	423,456	31,011	5,563	—
1921	458,710*	424,166	29,304	5,240	—
1922	485,829*	409,994	30,346	5,487	—
1923	444,869*	437,112	30,776	4,999	—
1924	473,270*	435,494	31,103	5,050	—
1925	473,006*		32,701	4,811	—

* Figures marked with an asterisk are provisional.

Small-pox.

Answering Mr. Groves, Mr. Chamberlain said he was reluctant to impose on the Ministry of Health the expense and research involved in stating how many cases of small-pox were notified to the Ministry of Health in 1924 and in 1925; how many proved fatal; the districts from which they came; the vaccinal condition and results of the cases in each district; and the vaccinal condition of each fatal case, including any vaccinations that may have been performed during the incubation period of small-pox. The Annual Report of the Chief Medical Officer for 1924 (pp. 33 and 37) gave for the country as a whole the number of cases of small-pox, with statistics of vaccinal condition. Complete figures for 1925 were not yet available. Mr. Groves further asked Mr. Chamberlain what methods were adopted by the medical officers of his department to decide definitely whether cases or illness examined by them were small-pox or not; and whether the vaccinal condition of the patients was taken into account as one of the factors to decide the diagnosis. Mr. Chamberlain said the medical officers of the Ministry who advised in regard to the diagnosis of suspected cases of small-pox were those who had had considerable experience of that disease, and in forming an opinion as to the nature of the illness they took into account all known factors, including the vaccinal condition of the patients. Mr. Groves: Just so! Mr. Groves further asked Mr. Chamberlain whether his attention had been drawn to the fact that during the years 1922, 1923, and 1924 the percentage of fatal cases of small-pox occurring among the unvaccinated patients was less than that of the vaccinated cases; and whether he would make a statement as to the attitude of his department in view of the bearing of this circumstance on the claims made on behalf of vaccination as a mitigant of small-pox. Mr. Chamberlain said the facts were as stated, but reference to the reports of the chief medical officer of the department for the years in question would show that, of the 16 fatal cases among vaccinated persons, only one was under the age of 35, while of the 22 fatal cases among unvaccinated persons, 7 occurred in infants under 1 year of age

and 6 in children between the ages of 1 and 9. Of the fatal cases among vaccinated persons, only one had been revaccinated, and in this instance it was doubtful whether the case was one of small-pox. The remaining 15 cases had been vaccinated in infancy, but had not been revaccinated. In his opinion these figures indicated the importance both of infantile vaccination and of revaccination at appropriate ages.

In reply to Captain Fairfax, Mr. Chamberlain said there was no record in the Ministry of Health of any case where venereal disease was directly caused by vaccination since the Vaccination Act of 1898 came into operation, and he was advised that the use of calf lymph, which became general after the Act, made it impossible for venereal disease to be transmitted by vaccination.

National Insurance.—Mr. Chamberlain, in answer to Mr. H. Williams, said the number of persons insured in Great Britain under the National Health Insurance Act during 1925 was not yet available. In 1924 they were 15,220,300. In answer to Captain Garro-Jones, Mr. Chamberlain said that, apart from reserve value, the funds held by approved societies in England and Wales on December 31st, 1924, were: (1) Sums standing to the credit of approved societies in the National Health Insurance Funds, including amounts in the Investment Health Insurance (2) sums invested by or on behalf of approved societies, £50,000,000; (3) cash in hands of societies, £1,000,000; making a total of £91,000,000.

A Unified Medical Service.—During the debate on the Navy Estimates Commander Bellairs asked the Financial Secretary to the Treasury whether the committee of investigation into the rates of pay of the medical services of the Navy and the Army and of the new medical service of the Air Force would be allowed to investigate the proposal for a unified medical service for all the fighting forces. In a written answer Mr. R. McNeill replied that the report of the Weir Committee of 1923 on the amalgamation of services common to the Navy, Army, and Air Force, and the consequential conclusions of the Government as explained to the House on May 30th, 1923, had been made available to the Committee. Mr. McNeill added that he could not anticipate the nature of the Committee's report.

Deaths from Alcohol.—The Home Secretary told Mr. Scurr that in London during 1925 inquests were held on 17 persons in which the verdicts attributed death to excessive drinking. This compared favourably with 31 such verdicts in 1923 and 35 in 1921. He could not confirm the assertion that the beverage in most of these 17 cases was methylated spirit, but on that assumption the figures gave some reason to hope that the introduction of pyridine as an ingredient, which began in May, 1924, had beneficial results. This assumption was supported by a substantial decrease in 1925 of the number of persons convicted of drunkenness whose condition was due to methylated spirit. The preventive measures already adopted appeared to deserve a more extended trial before further measures were considered.

Lead Poisoning.—On March 15th Sir William Joynson-Hicks, the Home Secretary, presented the Lead Paint (Protection against Poisoning) Bill, the object of which is to make better provision for the protection against lead poisoning of persons employed in painting buildings. The bill was read a first time.

Factories Bill.—In an answer to Major Glyn, the Home Secretary said he proposed to introduce the Factories Bill for consultation and discussion later in the session. The bill could not be passed into law this session.

Indian Subordinate Medical Staff.—On March 15th Colonel Applin asked the Under Secretary of State for India whether he was aware that no promotions to commissioned rank had been made in the Indian subordinate medical service since 1923; and, in view of the number of qualified men eligible for and awaiting promotion, he would take steps to ensure that their claims were dealt with at once. Earl Winterton replied that the circumstances were brought to the notice of the Secretary for India by the Anglo-Indian deputation which waited on him last summer. The Government of India was being asked for an early report on the subject.

Notes in Brief.

The model by-law enforcing the use of a mechanical stunning instrument before the slaughter of animals for food has been adopted by 190 local authorities, of whom 57 adopted it in the last twelve months.

Of 274 persons comprising the indoor staff of the Welsh Board of Health, 52 are fully conversant with the Welsh language. Recent appointments of higher executive officers to the Board were approved by Mr. Chamberlain in the ordinary course.

Deaths from influenza, tuberculosis, and cancer are not recorded separately in the Indian mortality statistics.

The gross revenue of the Central and Provincial Governments of India from opium in 1923-24 was £5,331,000. Figures for 1924-25 are not yet available.

Obituary.

W. PERMEWAN, M.D.LOND., F.R.C.S.ENG.,
Consulting Laryngologist to the Liverpool Royal Southern
Hospital; Late Lecturer in Laryngology, University of
Liverpool.

THE death of Dr. Permewan on March 9th came as a shock to many of his professional colleagues, and Liverpool has lost one of its foremost public men. He had been in precarious health for the past six months.

William Permewan was born at Redruth in Cornwall in 1865. After a sound general education he became a student of University College, London, took his M.B. degree with honours in materia medica in 1886, became M.D. in 1888, and F.R.C.S. in 1889. After qualification he held the post of resident at the Miners' Hospital in his native town. In 1887 Dr. Permewan went to Liverpool to fill the post of house-surgeon to the Northern Hospital, and later on he became head surgeon of the Northern Dispensary. It was during the tenure of this post, in set discussions on various subjects, that he developed and cultivated his ability to express himself cogently and forcibly, an ability which later on enabled him to enter into public affairs and win the esteem of his fellow citizens. Attracted early to specialism, he devoted himself to diseases of the throat and ear, and published several articles in the *Liverpool Medico-Chirurgical Journal* (The relation of the nose to chronic respiratory disease, Submucons resection of the nasal septum) and in the *Journal of Laryngology* (Laryngeal paralysis in chronic nervous disease). As a member of the Liverpool Medical Institution his communications were much appreciated for their lucidity, gracefulness of expression, and charm of voice. A good debater, he never lost the thread of his argument, and was quick to seize the weaknesses of his opponent. He was a vice-president of the Institution in 1902.

Dr. Permewan took a keen interest in municipal politics and was a member of the city council for six years. There he proved himself to be a valuable colleague, and his judgement, based on sound knowledge, coupled with his remarkable ability to seize essentials, paved the way to his being made a justice of the peace in 1906. Referring to the loss that the city had sustained in the death of Dr. Permewan, the stipendiary magistrate, Mr. Stuart Deacon, stated that Dr. Permewan was one of the most brilliant men on the bench of magistrates. In 1910 he contested in the Liberal interest Bootle, having as his successful opponent Mr. F. E. Smith, now Lord Birkenhead. It was on this occasion that Dr. Permewan revealed himself to be a politician of the first rank and a master in confronting successfully political audiences with his ready repartee. He made another attempt to enter Parliament later on in the same year, but in spite of his indomitable energy failed. Although greatly interested in public affairs, his reputation in his specialty increased so that in 1914 he was appointed lecturer in laryngology in the university, and he expounded with his native grace and literary gifts his subject to the delight of the students. He was president of the Philomathic Society and an active member in its debates. Dr. Permewan contributed thoughtful articles to the monthly reviews, in which he dealt with the prospects of the Liberal party, of which he was until within the last year a prominent stalwart. His speeches were always vigorous, convincing, and carefully delivered.

In private life Dr. Permewan was a genial man, and quite alive to the foibles of his many friends, at whom he would occasionally poke fun in his humorous way. He will be missed medically as well as politically, and at the funeral service held on March 13th a large number of his friends, professional and political, were present to show their respect for one held in high esteem by all classes. Dr. Permewan married a daughter of the late Dr. E. K. Muspratt. He had two children—a daughter who predeceased her father some six weeks before, and a son. Deep sympathy is felt with Mrs. Permewan and her son in this second bereavement that has befallen them.

Dr. G. E. GABITES of Timaru, New Zealand, who died on January 15th, was born at Christchurch in 1867. He was educated at Edinburgh University, where he graduated B.Sc. in 1891, and M.B., C.M. in 1894, and in 1898 he became F.R.C.S. Ed. He was resident physician at the Royal Infirmary, Edinburgh, in 1894, and a year later was appointed resident surgeon at the Royal Maternity and Simpson Memorial Hospital, Edinburgh. In 1899 he became surgeon superintendent of the Timaru Hospital. A matter in which he took particular interest was ambulance work, and when South Canterbury had progressed sufficiently to claim a corps he was appointed the first corps superintendent surgeon, and continued to hold that office up to the time of his death. He was an honorary Associate of the Order of St. John of Jerusalem. During the South African war he served with the New Zealand contingent, and was awarded the Queen's medal with four clasps. During 1917-19 he was camp commandant of the New Zealand training camp at Arapuni, and served as A.D.M.S. of the Otago military district from 1919 to 1920. For his services he was awarded the O.B.E. Dr. Gabites, who was lieutenant-colonel of the New Zealand Medical Corps Reserve of Officers, was a member of the South Canterbury Division of the British Medical Association. He is survived by his widow, two sons, and two daughters.

Dr. LOUIS BRIGHTWELL HAYNE of Harrogate died on February 14th, at the age of 56. He was the second son of Mr. Henry Hayne of Tunbridge Wells, and received his medical education at the University of Cambridge and St. George's Hospital. He graduated M.B., B.Ch. Cantab. in 1894, and M.A. and M.D. in 1897. After serving as house-physician and house-surgeon at St. George's Hospital, and house-physician to the Victoria Hospital for Children, Chelsea, he joined the late Dr. Ozanne of Harrogate in 1901, and continued to practise there up till his death. He was honorary physician to the Harrogate Infirmary, and during the war served as medical officer at Grove House Hospital, for which he was awarded the M.B.E. Dr. Hayne, who was a member of the Harrogate Division of the British Medical Association, is survived by his widow.

Universities and Colleges.

UNIVERSITY OF OXFORD.

Radcliffe Prize, 1927.

THE next award for the Radcliffe Prize will be in the year 1927. The prize, which is of the value of £50, is awarded by the Master and Fellows of University College every second year for research in any branch of medical science, comprised under the following heads: human anatomy, pathology, medicine, surgery, obstetrics, medicine, hygiene. The prize is open to any University who have proceeded, or are proceeding, to a medical degree in the University. Candidates must not have exceeded twelve years from the date of passing the last examination for the Bachelors of Arts, and must not, at the date of the award, be Fellows on the Foundation of Dr. John Radcliffe. Candidates must send in their memoirs to the Secretary of Faculties at the University Registry on or before December 1st, 1926. The award will be made in March, 1927. No memoir for which any University prize has already been awarded is admitted to competition for the Radcliffe Prize, and the prize will not be awarded more than once to the same candidate.

UNIVERSITY OF CAMBRIDGE.

At a congregation held on March 12th the following medical degrees were conferred:

M.B., B.CHIR.—W. A. Barnes, G. A. Metcalfe.
M.B.—A. W. Ewins.
B.CHIR.—I. C. P. Beauchamp, F. R. Sandford, J. W. W. Jepps.
* Admitted by proxy.

UNIVERSITY OF LONDON.

Mr. R. C. ELSLEY has been recognized as a teacher of orthopaedic surgery at St. Bartholomew's Hospital.

Dr. G. V. Aurep has been admitted to the Faculty of Medicine as from March 1st.

The Vice-Chancellor, the Chairman of Convocation, the Chairman of the Academic Council, and the Chairman of the Council for External Students have been appointed delegates of the University to attend the third Congress of Universities of the Empire in July next.

Professor E. C. Dodds (Middlesex Hospital Medical School) and Professor J. C. Drummond and Mr. D. T. Harris (University

clinical lecture demonstrations by the clinical staff, lantern lectures by the honorary director, anatomical lectures and demonstrations by Professor Waterston, physiological lectures and demonstrations by Professor Herring, clinical pathology by Dr. Matthew Fyfe, chemistry by Dr. Hynd, radiology, and clinical lectures at the Royal Infirmary, Dundee, by Professors Price and Patrick. The fee for the course is £5 5s., payable in advance. Members of the class who wish to carry out practical work may do so in the laboratories under supervision at hours to be arranged.

THE Fellowship of Medicine announces that Mr. A. Tudor Edwards will give a clinical surgery demonstration at the Westminster Hospital on March 31st at 2 p.m., free to members and ticket holders of the Fellowship general course. Beginning on April 12th, St. Peter's Hospital will hold a two weeks' course in genito-urinary diseases, including daily clinical sessions and a lecture each afternoon. The National Orthopaedic Hospital has also arranged a special comprehensive course from April 12th to 24th. From April 14th to May 5th there will be lecture demonstrations in electrotherapy at the Royal Free Hospital at 5.15 p.m., and an intensive course in proctology is to be held at St. Mark's Hospital from April 19th to 24th, with daily sessions, including lectures, demonstrations, and operations. This course will only be held if ten entries are received by April 12th. Copies of all syllabuses and of the general course programme may be had from the Secretary of the Fellowship of Medicine, 1, Wimpole Street, W.1.

A JOINT meeting of the Tuberculosis Society and the Society of Superintendents of Tuberculosis Institutions will be held in the Pathological Lecture Theatre, Cambridge, on March 25th, 26th, and 27th. Communications will be made by Sir Humphry Rolleston, Bt. (Regius Professor of Physic in the University), Sir St. Clair Thomson, Professors Collis and Lyle Cummins, and Drs. J. Crockett and G. Marshall. Dr. H. de C. Woodcock will demonstrate apparatus for artificial pneumothorax, and this subject will be discussed by Drs. Clive Riviere, Vere Pearson, and Parry Morgan, and Mr. Morrison Davies. Particulars may be obtained from Dr. F. J. C. Blackmore, Tuberculosis Dispensary, Maxey Road, Plumstead, S.E.18.

THE British Council of the International Congress for Life Saving and First Aid to the Injured, which held a meeting on March 17th, co-operates with similar societies in other countries in furthering interest in life saving and first aid. The third International Congress is being arranged in Holland in September of this year, and the fourth International Congress will be held in London in 1928. The British Council includes Sir William Collins, Sir Thomas Oliver, Professor E. L. Collis, Dr. Theodore Thompson, and Dr. D. A. Coles, who is chairman. Dr. H. N. S. Menko, 2, Grosvenor Gardens, Cricklewood, N.W.2, is the honorary secretary.

THE Section of Laryngology is arranging a complimentary dinner to Sir St. Clair Thomson, President of the Royal Society of Medicine, on the evening of Friday, June 4th. The dinner will be followed by a dance, and Fellows and Members may obtain tickets for themselves and their guests from Mr. Norman Patterson, 82, Portland Place, W.1.

A DRAWING-ROOM meeting was held at Grosvenor House on March 18th, when Viscountess Astor, the Bishop of London, and others spoke in support of the scheme of the Save the Children Fund to establish an open-air residential school for delicate London children.

A PARTY of two hundred and fifty American and Canadian members of the Inter-State Post-Graduate Medical Association of North America will this spring make a post-graduate tour to Italy, Switzerland, Czecho-Slovakia, Austria, Germany, Holland, and Belgium. The party will arrive in Paris on May 7th and the tour will terminate at Brussels on June 26th. The Foreign Relations Committee, of which Lord Dawson of Penn is chairman, and Mr. Philip Franklin, F.R.C.S., honorary secretary, asks us to state that twenty-five British medical men are invited to join the party in Paris and accompany it on the entire tour or any part of it. Further particulars can be obtained on application to Mr. Franklin, 27, Wimpole Street, London, W.1.

THE first Dutch Pedagogic Congress, which will be held at Amsterdam from April 8th to 10th, will consist of the following sections among others: Social pedagogy, psychology of the child, principles of pedagogy, abnormal children, delinquent and irresponsible children, school and home, and the history of education. Further information can be obtained from the secretary, O. van Veen, 1st Helmerstraat 36, Amsterdam. The thirty-first Dutch Congress of Public Health will be held on June 25th and 26th at Utrecht.

THE annual meeting of the International Society of Medical Hydrology is being held this year in Czecho-Slovakia from April 16th to 21st. The places to be visited include Karlsbad, Marienbad, Franzensbad, Prague, Pistany, and Tatras. A limited number of medical practitioners who are

not members of the society may join the party, but early application is essential. It is estimated that the railway fares to the frontier will cost about £11, and the cost of the seven days spent in Czecho-Slovakia, including subsistence and local travelling, is not expected to exceed £6. The honorary secretary is Dr. E. P. Ponton, 36, Devonshire Place, W.1.

MESSRS. CONSTABLE AND CO. (10, Orange Street, London, W.C.2), the English publishing agents of the League of Nations, have issued a list for the Information Section of pamphlets on various aspects of the League's work. The prices are 3d. for single copies of a pamphlet or £1 for one hundred copies.

THE Home Secretary gives notice that it is proposed to apply for an Order in Council, in pursuance of Section 8 (2) of the Dangerous Drugs Act, 1920, declaring that Part III of that Act shall apply to veronal and the other drugs of the barbitone group in the same manner as it applies to the drugs mentioned in Subsection (1) of Section 8 (morphine, cocaine, etc.), and to make regulations limiting the supply of the drugs to authorized persons or institutions or to persons for whom the drugs have been prescribed by a medical practitioner.

THE house and library of the Royal Society of Medicine will be closed from Thursday, April 1st, to Tuesday, April 6th, both days inclusive.

ADMINISTRATION of vaccines by mouth in the prophylaxis of dysentery, cholera, and typhoid fever has recently been organized on a large scale in the Union of Soviet Republics with encouraging results.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **THE EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the **BRITISH MEDICAL JOURNAL** alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the **BRITISH MEDICAL JOURNAL** must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the **JOURNAL**, should be addressed to the Financial Secretary and Business Manager.

THE TELEPHONE NUMBERS of the British Medical Association and the **BRITISH MEDICAL JOURNAL** are **MUSEUM 9361, 9362, 9363, and 9364** (internal exchange, four lines).

THE TELEGRAPHIC ADDRESSES are:

EDITOR of the **BRITISH MEDICAL JOURNAL**, *Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Mediscera Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 4737 Dublin), and of the Scottish Office, 6, Drumsheugh Gardens, Edinburgh (telegrams: *Assortate, Edinburgh*; telephone: 4361 Central).

QUERIES AND ANSWERS.

THE ADMINISTRATION OF OXYGEN.

"OXYGEN" asks for advice as to the best way of administering oxygen in lung affections, and, in particular, for practical clinical experience of Professor Haldane's apparatus described and illustrated by him in the **BRITISH MEDICAL JOURNAL** in 1917 (vol. i, p. 181).

PAIN IN PARALYSIS AGITANS.

"BIDDULPH" asks for suggestions towards the relief of pain in a case of paralysis agitans. The patient is a retired schoolmaster, 66 years of age, a bachelor, a lifelong abstainer; during middle life a heavy smoker, but not so now; always subject to insomnia. The trouble is of three years' duration. Parathyroid had no effect, but massage has greatly diminished the muscular rigidity, so that he can rise from a chair and walk with comparative freedom. The pain is chiefly in the upper arms and shoulders, and makes sleep almost impossible. After reading in this column about the successful use of hyoscine, this was tried. Beginning with 1/200 grain hyoscine hydrobromide by the mouth every fourth night, the dose was increased up to 1/75 grain, and even to 1/50 grain. These latter quantities upset him, so for some time he had 1/100 grain every fourth evening, and lately every third evening. The result is that he gets no sleep at all the first night; then follows a good day and a good night, followed by a fair day and a fair night; the third day he is as before.

HYPERPYREXIA.

DR. H. L. McCORMICK (Glasgow) writes: I examined a child to-day, aged 6 months, suffering from acute gastro-enteritis with convulsions. The axillary temperature, taken twice, was 109° F. and the rectal temperature 109.4° F. The child died half an hour later. Has any higher temperature been recorded in medical literature?

ALPINE "SUN BURNS."

"A. R." writes: I should be glad to know of the best remedy for the prevention of "sun" burns and the eczematous condition which follows while climbing in the higher Alps. They occur, as every climber knows, after traversing over snowfields, even without the sun shining.

TREATMENT OF LIPOMATA.

DR. A. Y. MASSOUDA (Cairo) asks for advice as to the treatment of a man, aged 31, who in 1920 developed a lipoma in the arm, and since then several others in the extremities. At the present time he has about twenty. The biggest is as large as a walnut. Our correspondent asks whether any medical treatment would cause the lipomata to disappear or at least prevent the appearance of new ones.

INCOME TAX.

Replacement of Car.

"J. V. C." bought a car in 1920 and sold it in 1925, buying another in replacement. What allowance is due?

"* * Treating the matter as one to be allowed for as a professional expense, it should be deducted, in the same way as other professional expenses, from the earnings of the year in which it was incurred—that is, of the year 1925—and will reduce the net profits of that year accordingly. It will therefore first affect the average assessable for the year 1926-27, and "J. V. C." will receive the full benefit of the allowance spread over that and the two following years.

LETTERS, NOTES, ETC.

ANOTHER DISEASE DUE TO FASHION.

"C. K." writes: During the last fortnight I have seen three cases of erythema intertrigo behind the ears in young women, due, in each case, to the covering of the ears with a wad of hair pressed down by a closely fitting hat worn nearly all day. When the ear was raised there was revealed what may best be described in the words of Mr. Mantalini as "a demn'd moist unpleasant"—and I may add steamy and smelly—surface, which reminded me forcibly of the condition sometimes found between the fingers when a hand has been bandaged up for days without due precaution. This word of warning as to the necessity for keeping the space behind the ears ventilated may save other devotees of fashion from a very unnecessary complaint.

UNIVERSITY REFORM IN LONDON.

DR. RICHARD GILLBARD (Wilkesden Green, N.W.), in the course of a letter on this subject, writes: "Bloomsbury site are prodigious in their facilities, as Mr. Fisher has said, would res were good-will. The London University we cherish is for all—it concerns others besides senates, councils, and graduates: every man and woman with vision. Dr. Graham Little says the renewed discussion of the Bloomsbury site is fatuous because of the option ceasing on the first of next month. Let our reply be Mr. Fisher's: an appeal to the public to build a home in the heart of our city, to which students and pilgrims shall come from all parts of the Empire and rear aloft the greatness of London. Then those who oppose will, as Burke said, seem to oppose the decrees of Providence."

RECTAL INJECTION OF TARTAR EMETIC FOR BILHARZIASIS.

WE have received the two following communications from Tanganyika Territory, East Africa, on the treatment of bilharziasis by rectal injections of tartar emetic.

DR. WILLIAM H. DYE, Sanitation Officer, Tanganyika, writes: When in Nyasaland, Dr. H. F. Wilson kindly brought his method to my notice, and as I was at that time stationed in a place where infection with both *S. haematobium* and *S. mansoni* was extremely common and usually heavy I gave the method a thorough trial. I found, as Dr. Barcroft Anderson (see BRITISH MEDICAL JOURNAL, October 17th, 1925, p. 700) did, that large amounts (up to 16 grains) could be injected per rectum, even in small children, without any toxic effects. It is obvious that only a fractional part of these heroic doses can be absorbed, as no untoward symptoms were ever noticed. In the vesical form it frequently cleared the ova from the urine, only to relapse at short and variable intervals. I think that the explanation of its action is that, when given intrarectally, it is absorbed in very small amounts, but sufficient to kill the adult and mature flukes that are at the time in the rectal or bladder walls, but has little or no action on those situated at a distance when the drug has become less concentrated. Good results might therefore be expected in very lightly infected cases—an uncommon event in natives. I cannot agree that the ova of bilharzia are killed by tartar emetic. If ova are put in a saturated solution of tartar emetic and left for two hours no hatching takes place, but on removal of the drug by repeated centrifugalization and the

addition of water they will hatch out as readily as in the control tube, the long contact with a very high concentration of the drug making no difference. It can also be proved experimentally that while the ova are quite unaffected by this drug, the miracidia, while standing a fairly high concentration, are more quickly affected, and the cercaria even more so. Clinically we know that the adults are killed by relatively very small doses. This is what might be expected, as the adult flukes live normally a very protected existence, while the ova have to be prepared to stand varying degrees of acidity, alkalinity, and salt concentration in the urine, and may be exposed to many conditions after they leave the body. Much stress has been laid on the appearance of dead or so-called "black eggs" in the urine, as evidence of the lethal action of the drug on the ova. If a heavily infected urine is examined a certain number of these ova will always be seen. They may become more evident after treatment, when they remain the only ones to be discarded, being merely foreign bodies to be cast off; the healthy egg having the power of dissolving the tissues ahead, and therefore accelerating its progress. In conclusion, I would agree with Dr. Christopherson (BRITISH MEDICAL JOURNAL, November 7th, 1925, p. 866) that few medical men practising in the tropics will admit that an enema is simpler or quicker than an intravenous injection. The finding of the smallest vein with a sharp needle only requires a modicum of practice. In addition, it is surely safer to give a known dosage of a drug than to rely on an unknown quantity absorbed, which must be an extremely variable factor. I have found in some hundreds of cases that intravenous tartar emetic in sufficient dosage is safe, simple, and absolutely efficient.

DR. D. V. LATHAM writes: In the BRITISH MEDICAL JOURNAL of October 17th, 1925 (p. 700), Dr. J. Barcroft Anderson wrote that, following the lead of Dr. H. F. Wilson, he used the rectal method exclusively of administering tartar emetic for the treatment of bilharziasis. The simplicity of the method and the fact that the patients need not be detained for a long period appealed to me, and I experimented with a typical case. The results of the treatment were entirely unsatisfactory. The patient was a native boy, aged 11 years. He was given four rectal injections, at weekly intervals, of 4, 6, 8, and 11 grains respectively. The urine was examined every four days from the commencement of the treatment, until twelve days after the last injection, and on every occasion ova were found. On the last two occasions the urine was allowed to stand and live free embryos were seen. I followed Dr. Anderson's technique and kept the patient recumbent with the hips raised for half an hour after each injection, and in no case did the patient go to stool sooner than six hours after the injection. The injections had no more effect on the patient than if they had been normal saline. Check cases treated with the same batch of tartar emetic by the intravenous method responded in the usual way. I am forced to the conclusion that antimonium tartrate is not absorbed from the rectum.

SALICIN IN PSORIASIS.

DR. D. ROBERTS (Holyhead) writes with reference to the paragraph on this subject published in the *Epitome* of March 6th, 1925 (para. 258), that mention should have been made of the late Dr. Radcliffe Crocker, who prescribed salicin for psoriasis many years ago. Dr. George Pernet, the author of the article in the *Archives of Dermatology and Syphilology*, refers to the work of Dr. Radcliffe Crocker, with whom he was associated for about seventeen years.

COVERED MOTOR BUSES AND FRESH AIR.

DR. JOHN N. BEADLES (Streatham) writes: The love of fresh air is considered a British characteristic, and writers like Jerome K. Jerome poke fun at the awful atmosphere of a Continental railway carriage, a condition which it takes the audacity of an American tourist to alter. But in large cities like London it is not so easy to get this fresh air, and a large proportion of its citizens never enjoy robust health from sheer want of it; however, a splendid opportunity is given to many of getting one hour's fresh air every day by travelling to and from work on the top of a motor bus. In the book on *Home Nursing* issued by the St. John Ambulance Association it is stated that fresh air is so vital to a nurse that an hour's ride on a motor bus will often do her more good than lying down for two hours; a remark which I should certainly endorse. I hope this opportunity is not going to be taken away from the public by the suggested alteration in the motor bus.

* * We entirely agree with Dr. Beadles.

SUNSHINE RECORDS.

DR. H. D. BISHOP (M.O.H. States of Guernsey) asks us to state that he gave Plymouth for Portsmouth in the table published last week (p. 514). The entry should have been Portsmouth 1,923 hours.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 43, 44, 45, 48, and 49 of our advertisement columns, and advertisements as to partnerships, assistantships, and locum tenencies at pages 46 and 47. A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 99.

THE TREATMENT OF EXOPHTHALMIC GOITRE.

I.—GENERAL MANAGEMENT OF CASES.

BY

FRANCIS R. FRASER, B.A., M.D.,
F.R.C.P. Ed.,

DIRECTOR OF THE MEDICAL UNIT, ST. BARTHOLOMEW'S HOSPITAL;
PROFESSOR OF MEDICINE, UNIVERSITY OF LONDON.

THE general management of cases of exophthalmic goitre is so wide a subject that it is not possible, in the time allowed, to refer to many important methods of treatment. The cause of the disease is unknown, so no treatment directed at the cause is possible. Recent developments, however, have made it advisable to review the situation in order to improve the general management in the light of these developments. They are:

- (a) The reintroduction of treatment by iodine;
- (b) The recognition of thyroid disease as a cause of auricular fibrillation and heart failure; and
- (c) Improved skill in the surgery of the thyroid gland and in the selection and preparation of patients for operation.

CLASSIFICATION.

It is unfortunately necessary to discuss briefly what is meant by the term "exophthalmic goitre." If we exclude cases of cretinism and myxoedema, and cases of simple goitre in which there are no symptoms other than those of an enlarged thyroid gland or such as are the mechanical results of the enlarged gland, and omit cases of thyroiditis and of malignant disease, there remains a large group of cases of goitre with symptoms of thyroid intoxication. The term "hyperthyroidism" is frequently used in the same sense as "thyroid intoxication" is used here, but, for various reasons which cannot be discussed now, the term "hyperthyroidism" is unsatisfactory and is being gradually replaced. Among the cases with symptoms of intoxication there are those with diffusely enlarged, very vascular goitres, and the classical picture of Graves's disease with its eye signs, tremor, tachycardia, and peculiar excitable nervous and mental state. There are others in whom the symptoms of intoxication appear after perhaps years during which a simple goitre has been present. In these cases the general intoxication is usually less, the eye signs may be slight or absent, but the cardiac disturbance is relatively more prominent. This same clinical picture is seen also in a larger group of cases that have no previous history of simple goitre, but in whom the enlargement of the gland is irregular, or the gland is less vascular and harder than in the typical form, or scarcely enlarged at all.

In the first group histological examination usually shows a change involving the whole gland which suggests great activity of the secreting cells and an absence of colloid storage. In the other groups areas of similar activity are seen, but they are localized, colloid storage is present, and in addition a fine or a coarse fibrosis. The fibrosis may be so coarse as to give the appearance of multiple adenomata, and various forms of degeneration may be present in localized areas. In the present state of our knowledge I propose to use the terms suggested by Williamson and Pearce,¹ and call the first group of cases "Primary Graves's disease," and the others "Secondary Graves's disease." This is practically the classification of Möbius.² The terms of Williamson and Pearce are based on histological examination, and although it is clinically possible to recognize many cases as belonging to the primary group and many as belonging to the secondary group, there are many that are difficult to place on clinical evidence alone.

¹ An opening paper read at the joint meeting of the Sections of Medicine, Surgery, Therapeutics and Pharmacology, and Electro-Therapeutics of the Royal Society of Medicine on March 9th, 1926.

I find it difficult to recognize a clear distinction between those with eye signs and those without, and therefore at present include the cases described by Plummer³ as "toxic adenoma" in the secondary group, which includes also "toxic adenomatosis," "toxic goitre," "incomplete" forms, "formes frustes," "thyro-toxicosis," etc. Without doubt further work and experience will allow of more exact differentiation, but this distinction between the primary and the secondary groups has some importance in treatment and prognosis.

ETIOLOGY.

We are quite ignorant of the cause of primary Graves's disease, and quite ignorant of the cause of the onset of symptoms of intoxication in secondary Graves's disease; but in both forms of the disease exacerbations and relapses are common features, and there are certain factors associated with these. Adolescence, pregnancy, the puerperium, and the menopause appear to be dangerous events, and may be associated with increased intoxication. Infections and, above all, septic tonsils, nasal sinuses, and teeth sockets, are particularly important because so often overlooked, and are frequently responsible, not only for exacerbations and relapses, but also for maintaining a high level of thyroid intoxication. Worries, mental stresses, and shocks are also important, and are often acknowledged by the patients, but are sometimes not disclosed until skilfully inquired for.

COURSE OF THE DISEASE.

Before the measures to be employed in management can be considered it is necessary to have as clear a knowledge as possible of the natural course of the disease. This knowledge is difficult to obtain, since hospital records deal with the more severe cases only, and social position enters greatly into the possibilities of adequate management. Barker⁴ has stated that the course of the disease associated with diffuse hyperplasia of the whole gland—that is, primary Graves's disease—"is probably two or three years, no matter how you treat it (medically, surgically, or radiologically)." He mentions, however, that relapses occur. Kessel, Lieb, and Hyman⁵ studied 50 cases, and maintained that sufficient recovery to enable a resumption of work resulted from rest and symptomatic treatment only, without surgical or x-ray treatment. Read⁶ published composite curves to show that the progress, as measured by the basal metabolic rate, is much the same, whether general medical measures, x rays, or surgery are employed. Holmes, Means, Porter, Richardson, and Starr⁷ confirm this in general, but show that treatment by subtotal thyroidectomy has a definite effect on the course. My experience is, in general, in agreement with these views, but the frequency of relapses robs the main contention of much of its significance.

In secondary Graves's disease, although the general level of intoxication is not so high, the tendency to recovery is not so great. The condition is much more chronic, and after years of exacerbations and remissions, cardiac disturbances, auricular fibrillation, heart failure, mental disorders, and increasing emaciation not infrequently develop, and may so dominate the picture that the causal condition is not always recognized. The basal metabolic rates seldom rise to the heights seen in the primary form. I suspect that a case showing the features of primary Graves's disease in early life may later present the clinical and pathological features of the secondary form, but there is at present a lack of dependable records of the life-histories of these cases, and the ultimate results are still quite unknown.

MANAGEMENT OF PRIMARY GRAVES'S DISEASE.

Even if there is a tendency towards spontaneous recovery in primary Graves's disease, cases may flare up and die with severe intoxication. What is perhaps of greater importance is that during the period of months or years in which the disease is running its course the patients are often quite unable to carry on their work. It is necessary that they should be managed so that the level of intoxication at which the disease runs its course should be as low as possible.

Rest.

Of all the methods of treatment rest is the most important. The patient should be put to bed and observed for a week or more without any other form of treatment, so that the severity of the condition may be estimated. Physical rest is not more important than mental rest. Whether the rest should be given in hospital, at home, or in a nursing home, must be a matter for careful consideration in each case. Temperaments, not only of the patient but also of the relatives, must be considered. The financial status is important. The usual daily duties must be known. After the first few weeks the rest need not be absolute, for if too strict it leads to restlessness, and some employment for body and mind has a beneficial effect on both. If the heart is grossly dilated or if the general intoxication is increasing, strict rest is essential. I do not think that tachycardia or a moderately increased basal metabolic rate is an indication for the strict enforcement of rest in bed. The influence of the mind in patients suffering from this disease is great, and detailed attention to the surroundings and to the cheerfulness of the attendants is always necessary.

Elimination of Sepsis.

During the preliminary period of rest a thorough search for infections is made. Even if no evidence is found of tonsillar infection, a history of sore throats during the onset justifies an examination by a throat specialist. Sinuses and teeth must be examined, and any suspicion cleared up. In several cases that were not improving as quickly as was hoped for an onset of acute tonsillitis has unmasked buried sepsis, and such an occurrence, though it causes a distressing exacerbation, should be viewed with satisfaction, as a cause for the unsatisfactory condition has been found and can be dealt with. In 60 cases of all forms of Graves's disease that have been under the care of the Medical Unit at St. Bartholomew's Hospital in the last five years tonsillectomy was performed in 14, and in each case for gross sepsis. In such cases the disease runs its course at a lower level after the operation, and the danger of a serious exacerbation is greatly diminished.

Iodine.

The reintroduction of the use of iodine has been of considerable value in enabling the disease to run its course at a lower level and in checking the severity of the exacerbations, but it need not be considered in detail now, as this subject has been discussed at a recent meeting of the society. The place of iodine in the general management must, however, be briefly summarized. After allowing one to two weeks' complete rest without other treatment, so that an estimate can be made of the degree of intoxication and of the various factors present, iodine may be commenced in daily doses of 15 minims of a 10 per cent. solution of iodine in 95 per cent. alcohol ($1\frac{1}{2}$ grains of iodine). The alcoholic solution is best given in a wineglass of milk. In the course of a few days the pulse rate and the basal metabolic rate commence to fall, and the body weight to rise. When the maximum effect is obtained, the daily dose can be dropped to 10 minims, and later to 5 minims, and many patients continue to take this small dose for months or years. It is difficult to demonstrate the effect in these long-continued administrations, but the patients in nearly every instance say that they feel better when taking it. In the event of a relapse, usually due to infections, the dose is again increased. Much larger doses are used during the so-called "crises" by American workers, but our own experience of these dangerous relapses is too limited to allow of conclusions. In the secondary type of the disease harm may result from even moderate doses, so that the patient should be under careful supervision while taking iodine, as the distinction between the two types is not always possible. My own impression is that in any case of thyroid intoxication a dose can be found that will cause improvement. After surgical treatment convalescence is greatly aided by the administration of iodine for several months at least.

Diet.

Diet must be mentioned, if only to say that at present there is no clear indication of the value of any special diet. The diet must be liberal, as the patients are often hungry, and since their general metabolism is raised it may be presumed that they require a higher calorie intake than is normal for their size and their external activities. At present an ordinary diet arranged to suit the habits and status of the patient is all that is indicated, but it must be liberal.

Many other methods of treatment—by drugs, by hydrotherapy, by physiotherapy, etc.—have been used, but I believe that they are all either symptomatic or exploded, and it would but cloud the main issue to discuss them, however important as symptomatic treatment they may be. Of treatment by x rays and by insulin I have practically no experience and will not discuss them, but doubtless others will consider them fully to-night.

Results and Indications for Surgical Treatment.

If treatment is carried out on the lines I have mentioned, most of the cases of primary Graves's disease make a satisfactory recovery and return to nearly normal conditions of life and efficiency. Many, perhaps, do not require even as much treatment as I have suggested, but these we are not in a position to study in hospital practice. Of the cases that attend hospital, many are quite unable to carry out such treatment. The absence from heavy household duties or from business worries, that is so essential, results in other worries or in financial straits that rob the rest of all value. Such patients must be returned to their ordinary duties within a relatively short period of time. By surgery this can be effected.

If under good conditions a satisfactory improvement has not been effected in six months so that a return to work can be at least attempted, operation should be considered. If at the end of six months the pulse rate at rest remains constantly above 100, or if serious cardiac disorders such as auricular fibrillation develop, operation should be considered.

TABLE I.—*Exophthalmic Goitre, 1921-25.*

Type and Treatment.	No. of Cases.	Results.				
		Good.	Poor.	Bad.	Not Traced.	Died.
PRIMARY (32 cases):						
Non-surgical	18	8	3	2	2	3
Surgical	14	13	—	—	—	1
SECONDARY (23 cases):						
Non-surgical	10	5	—	1	1	3
Surgical	13	12	—	—	—	1
DOUBTFUL (5 cases):						
Non-surgical	5	2	—	—	3	—
Surgical	—	—	—	—	—	—
ALL TYPES (60 cases):						
Non-surgical	33	15	3	3	6	6
Surgical	27	25	—	—	—	2
Total	60	40	3	3	6	8

Of the 32 cases of primary Graves's disease that have been in the wards under my direction during the last five years 14 have required operation—one only for persisting general intoxication, 3 because of auricular fibrillation and heart failure, and 10 on economic grounds (see Table II). Of the 18 that did not have operations, 8 are doing well, 3 improving very slowly, 2 are doing badly and are practically confined to bed, 3 are dead, and 2 lost sight of (see Table I). Of the 14 that have had operations, one died immediately after, and I feel sure that with our greater experience now in the preparation of the patient and the selection of the optimum time this death could have been avoided. The other 13 are all doing their work successfully, but still show signs of the disease, and at times of stress recognize that they have a limited capacity.

MANAGEMENT OF SECONDARY GRAVES'S DISEASE.

The general management of cases of secondary Graves's disease is on similar lines. The degree of general intoxication is usually less, and many cases can be guided through life with little interference with their activities. The effect of iodine is generally less marked, and great care must be taken not to do harm rather than good by its use. The more chronic course and the absence of the tendency to spontaneous recovery render these cases more serious in their prognosis—the more so since it is in them that cardiac disturbances and congestive heart failure form a prominent feature. In them, therefore, surgical treatment is more clearly indicated once a serious degree of crippling is reached. A few years ago the cases of auricular fibrillation and oedema would have been considered impossible cases for successful operation, but by the improvement in surgical skill, and the more efficient selection and preparation for operation, these are the cases in which the indication for surgical treatment is most clear (Dunhill, Fraser, and Stott¹) and in which the results are most striking. Of 23 cases of secondary Graves's disease 10 were treated on general lines, and of these 5 are continuing satisfactorily, one is doing badly and has now developed auricular fibrillation, one has been lost sight of, and 3 died before they could be brought to a satisfactory state for operation. Of the 23, 13 have had thyroidectomy operations. One of them has recently died in hospital when readmitted for further thyroidectomy two years after a lobectomy; the other 12 are doing well—7 of them had auricular fibrillation and heart failure, and are all now free of cardiac irregularity. In preparing these cases for successful operation careful treatment with digitalis and iodine and much patience are necessary. In some the auricular fibrillation disappeared spontaneously after operation, in others quinidine was necessary to effect a return to normal rhythm.

TABLE II.—Indications for Surgical Treatment.

Type.	No.	Indications.			
		Toxic.	Cardiac.	Eyes.	Economic.
Primary	14	1	3	—	10
Secondary	13	2	8	2	1

In considering the high proportion of cases operated on in our series it must be remembered that we only see in hospital the cases that are doing badly, or that are not improving satisfactorily relative to their financial position or the necessity for an early return to work. That these cases can be restored to economic efficiency, or saved from invalidism or from death, is dependent on the co-operation of a skilled and experienced surgeon; but both the physician and the surgeon must guide continually for long periods, both before and after surgical treatment, to obtain the maximum beneficial results.

CONCLUSIONS.

The differentiation of types of exophthalmic goitre is important in treatment and prognosis. In the present state of knowledge the separation into primary Graves's disease and secondary Graves's disease is of value. By means of rest, the administration of iodine, and the elimination of sepsis, the level of intoxication at which the disease runs its course can be lowered, and most cases require no other treatment. By improvement in the preparation and selection of cases for operation, and by increased surgical experience and skill, cases when necessary can be restored to economic efficiency at an early date, and others can be saved from invalidism and death.

II.—SURGICAL TREATMENT OF EXOPHTHALMIC GOITRE.*

BY

T. P. DUNHILL, C.M.G., M.D.

(From the Surgical Professorial Unit, St. Bartholomew's Hospital.)

I SHALL speak almost entirely about the operative treatment of exophthalmic goitre because I have been requested to do so; but I wish to make it clear in the beginning that I do not regard operation as the one and only treatment for every stage of this disease. For some stages, however, I do regard it as the main treatment.

It is impossible to compress into a twenty minutes' address all the material which is of interest, therefore I propose to leave out much, to skim rapidly through other aspects of the subject, and to concentrate on such as appear to be most profitable for discussion. I have thought that it would best serve this purpose to speak under the following headings: (1) How cases are selected for operation; (2) how operation can be made safe and effective; (3) death rate; and (4) end-results.

Every case of toxic goitre must be treated on its own merits, but if we are to discuss principles of treatment we must have a working classification of cases. It can be simple, and must perforce be arbitrary. For other purposes we have the masterly classification of Scott Williamson and Miss Pearce,¹ but the one I speak of is a simple sorting out of cases. I divide patients into five classes as follows:

Simple Classification.

- I. Patients in the first six months of Graves's disease.
- II. After the first six months and before the stage of heart failure.
- III. Cardiac failure or/and severe oedema.
- IV. *Formes frustes*.
- V. Toxic adenoma.

I. Those patients in the first six months of Graves's disease. They differ in degree. In some the commencement is insidious with so little obvious disturbance that the diagnosis is at first unsuspected. In some it starts much more abruptly, all the signs developing early, sometimes accompanied by severe gastro-intestinal disturbance.

II. Those who, at the end of six months, have not regained normal health but who have not yet reached the stage of heart failure. Those in whom the symptoms were slight have settled into a state of chronic ill health. Those with a severe onset have also settled into a more chronic condition. The disability of patients in this class may vary within wide limits; they may carry on their work, better at times, worse at times; generally speaking they are too ill to work. The majority of the patients who wander from hospital to hospital are in this class.

III. Those from the previous classes who now have visceral degeneration, chiefly failing hearts, as shown by permanent auricular fibrillation, or marked oedema or anasarca. I do not mean simply swelling of feet or ankles. These patients are completely invalided. In this class we must also place those in whom the restlessness of the disease has caused such mental disorder that it has become practically impossible to nurse them in their own homes, and also those in whom glycosuria has developed.

IV. *Formes frustes*. We each have our own idea as to what these are. I take the term to mean cases that are not typical: where, with some symptom of Graves's disease, such as exophthalmos, there is excessive obesity, or where, with the other symptoms characteristic, there appears to be no goitre present. I do not take it to include toxic adenoma.

V. Cases which have been described and published by all of us, called by Plummer "toxic adenoma," by others "secondary Graves's disease"—not really Graves's disease at all. There is a unilateral or a nodular goitre which has existed for years without giving trouble. Then cardiac signs, often of a serious grade, have developed, but the nervous phenomena are absent or only slightly developed.

* A paper read to the Royal Society of Medicine on March 9th, 1925.

Patients in this class scarcely come into our discussion to-night, and they are not included in my statistics, but they must be mentioned so that our minds may be clear as to what we are talking about.

That is an arbitrary division, but it gives a working plan on which we can begin to discuss the question of operation.

How do we view the patients in each of these classes as regards the advisability or the necessity for operation?

Class I.—It may be stated as a general rule that exophthalmic goitre patients in the first six months of the disease do not require operation. Cases that are mild should be piloted in ways that have been sufficiently indicated to you. There must be many people who nearly fall victims to the disease, but just do not. There must be many who fall victims who could be cured if, at that early stage, the causes that induced it could be removed. The very grave cases commencing with vomiting and diarrhoea require careful management in ways that have also been indicated to you, and it must rarely happen that, in either the mild or the grave case, the best interest of the patient would be served by operation. During this six months most patients who have not been cured by medical means reach a point of maximum severity and then subside into a chronic stage. These constitute the second class.

Class II.—It is in this stage that there will be most dispute regarding the advisability of operation. It has been stated by Barker² that all patients get well equally quickly, whether they are treated medically, by x rays, or by operation, and that the average time taken is two or three years. Those practitioners whose experience has made them feel that this is true, and whose patients can afford the time and obtain the necessary nursing, will naturally and rightly treat their patients along medical lines. But first we want to know if that statement is true. It is not my experience. Of the 831 patients I have operated upon for exophthalmic goitre I have made a careful analysis of the histories of 170 consecutive cases, and have been able to determine fairly accurately the length of time these patients have been ill before operation was performed. The accompanying table shows these periods.

Number of Years during which 170 Consecutive Exophthalmic Goitre Patients have Suffered from the Disease before Operation.

Under 4 years.	Over 4 years.	Over 6 years.	Over 8 years.	Over 10 years.
102	63	48	37	32

Another fact to be borne in mind is that all the patients in Class III, the class with visceral degeneration, which we come to next, are examples of patients in whom the course of the disease has not been arrested, so that in considering the welfare of those who constitute Class II we must take into account the morbidity and the economic factor. This class is largely made up of women in the early middle period of life—young women who have to earn their living, and mothers of families. Therefore, in this class the social position of the patient counts for much. If the individual can afford to live a sheltered life with efficient nursing, possibly for years, well and good. The practitioner will watch the heart and mentality of the patient, and if either shows signs of being affected it will indicate that something more radical should be advised. With the poorer patient it is altogether otherwise. I find numbers of these patients coming to the out-patient department, ill, unable to work, with no place where they can be nursed; and with all this having in some way others dependent on them. It seems to me essential to cut short the disease and restore the patient to an industrial plane as soon, after the first six months, as it is realized that the patient is not improving.

Class III.—Patients who have drifted on through the first and second stages until the heart has given way under the continued intoxication. There is auricular fibrillation or permanent oedema or both. In the first class operation is rarely indicated; in the second class opinions may differ, but in this class I believe medical treatment can rarely restore the heart to permanent normal rhythm and functional efficiency. This result is now being achieved by operation in a sufficient number of cases to make us know that very striking benefit can be depended on.

Class IV.—Formes frustes. Different practitioners have different ideas as to what is meant by this. I do not take it to mean the toxic adenomatous condition accurately described by Plummer and more generally noted by many observers, but a condition in which the aspect of the patient appears to be that of Graves's disease, and in which there is some sign which appears unusual or wanting. For example, the patient, instead of being thinner than normal, is grossly fat, or exophthalmos is present and rapid heart, but there is no detectable enlargement of the thyroid gland. A clearer appreciation of the pathology of these conditions will be obtained from the work of Scott Williamson and Pearce referred to above.¹ I think we should not let these cases, which really form a very small proportion of the total number, blur the discussion, for I take it that we are making an attempt to get a clear view of the chief problem—namely, the position that operation should take in the different stages of typical exophthalmic goitre, beginning at its inception and going on to the late stages of cardiac failure; but because operation is of great value in some stages, it should not be pushed as the treatment in every kind of thyroid dystrophy.

Class V.—These patients can be gravely disabled by thyroid toxæmia, with oedema and irregular heart action. I believe they cannot be cured by medical means. At any rate, patients are not infrequently seen who have been completely invalidated for eight or ten years under good medical guidance, and during all this time the disease has steadily progressed. The danger of operation is not so great as in true Graves's disease, and the response to operation is prompt. These are not classed among my cases of exophthalmic goitre.

I have stated when I regard operation to be advisable. If it is helpful to some patients, it will be necessary to be satisfied on two points: (1) How can it be made safe? (2) How can it be made effective?

(1) How can Operation be made Safe?

By ensuring that the patient has no other load to carry besides the disease itself. It is surprising to what extent patients are still sent for operation with foci of gross sepsis present. This is very reprehensible. The majority of patients improve obviously when septic foci are cleaned up, and in an operation where the margin of safety is narrow enough every factor which reduces this margin should be eliminated. It should not be necessary to have to insist on this at this late period.

By rest in bed. It takes several days for the pulse rate to come down to its resting level when a patient is put to bed.

By iodine medication. This should be commenced as soon as it is seen to what extent the pulse rate has dropped as the result of rest and freedom from worries, usually about the third day. Not only will iodine further reduce the pulse rate, with the associated improvement in the patient's condition, but it will induce a definite change in the pathological state of the gland which makes the operation safer.

By confidence between patient and surgeon. It is not enough that confidence has been established between patient and physician. On the operation morning the surgeon must come as a friend, not as a person to be feared. This is not an emergency operation.

By adjusting the amount done at one operation to the patient's strength. This is most important, and the surgeon must be able to gauge it. It is always tempting to continue and get the complete job done in one operation. The patient who has been ill for a long time will often plead for it to be finished at once; and for the surgeon it is vastly easier to deal with the second lobe in a field unhampered by scar tissue. This is sometimes possible, and, if so, it is the right thing to do; but until the surgeon can judge this he will tell the patient in the beginning that two operations are necessary, and then, without disappointing her, do at one stage only what is within her strength.

In dealing with the third class—patients with dilated hearts beating irregularly, and with oedema—safety is only attained by the closest co-operation between surgeon and physician. In this class the results obtained are sometimes so good as to be hardly credible, but the margin of safety

is very narrow. A surgeon may be able, but can scarcely be expected, to sort out flutter from fibrillation, and know from an electro-cardiogram when heart-block is present. Nor does the surgeon know just the amount of improvement in the pulse deficit that can be expected; the amount of digitalis that will achieve this, and how the dosage of this is to be planned; nor, when a patient is waterlogged, can a surgeon be expected to know how best to employ the diuretics or measure fluid intake against urine output. Therefore in his hospital he will associate himself with a physician who is interested in these matters, and day by day the two will work in their wards together. Without this close co-operation patients in this class cannot be operated upon safely or the desired result attained.

Anaesthesia must be considered. I regard chloroform as unsafe. Gas and oxygen with a little ether, given by the endotracheal method, is safe and interferes less with the surgeon than any other method. If a surgeon will take the trouble and give the necessary time before the operation, local anaesthesia gives a comfort in working and a freedom from bleeding which is attained in no other way. Freedom from bleeding saves much time at the operation, and this saving of time, as well as the diminished loss of blood, is of importance to the patient. In cases of auricular fibrillation I believe that local anaesthesia is essential.

If these precautions are taken—and always excluding the moribund—there are few patients who cannot be carried through operation with a reasonable degree of safety; but no consideration of urgency on the part of the patient, or convenience on the part of the surgeon, should ever tempt him to operate at a time other than that which is the optimum, taking all the factors into account.

(2) How can Operation be made Effective?

There are many patients who have been operated upon for exophthalmic goitre who are not cured. Dr. McNee stressed this point on March 3rd (BRITISH MEDICAL JOURNAL, March 13th, p. 478). The earlier publications on operative results were misleading. Kocher⁴ stated that removal of one lobe with the isthmus, and ligature of an artery of the other side, cured 83 per cent. of cases. Similar statements were published by American surgeons. Eighteen years ago I had insisted that this was not so, and I have insisted continuously since.⁵ The remaining lobe is bigger than the whole normal gland, and very toxic. It is not reasonable to suppose that the patient could be cured while all this remained. This must be realized in the beginning. The removal of the first lobe is comparatively easy. Removal of the appropriate amount of the second lobe is more difficult. The approach is through scar tissue; the anatomical planes may have been destroyed by adhesions; and an extremely vascular gland is to be cut through; but unless the surgeon is prepared to undertake the second he must not do the first. Removal of one lobe improves a patient so much at first that patient and surgeon are pleased; but this result is so far short of a cure that, if left at that, it can only bring the operation into disrepute. The pulse rate will not remain down; the eyes will not recede, and in patients with auricular fibrillation there will not be restoration to normal rhythm. To make the operation effective sufficient gland

substance must be removed to reduce the secretion to the minimum compatible with the physiological needs of the body.

Death Rate.

The death rate for this operation will vary within wide limits. It will vary according to the type of patients operated upon, and greatly according to the time selected for the operation in each individual, and the care with which the preliminary treatment has been carried out. Some surgeons will be careful for their statistics; others will undertake operation at some risk on patients who, without operation, are, so far as can be judged, doomed to complete invalidism; and it will naturally vary according to the experience of the operator. My own death rate in 831 operations for Graves's disease—excluding toxic adenoma—is 2.9 per cent. It became rather higher three years ago when we were feeling our way with some very severe cases, but owing to better preliminary treatment, selection of time, and, at hospital with severe cases, the co-operation of my medical colleague Professor Fraser,

85 patients were operated upon between the last two deaths.

The Advisability of Operation.

It may be asked if the risks of operation are only to be successfully negotiated by extreme care; if a certain degree of skill and judgement is necessary, and if there are other satisfactory methods of treatment available; if Dr. Barker is right when he states that patients recover in two or three years whatever the course pursued, then why operate? Well, is that statement true? I have had my last 170 consecutive cases analysed very carefully. Of these, I find

that 68 have been ill over four years, 48 over six years, 37 over eight years, and 32 over ten years. Therefore, in time alone, wastage is very high.

The Condition of these Patients.

I find that of these 170 patients 30 have had a heart beating with permanently irregular rhythm. Of most of these I have electro-cardiographic records. Some were far too ill to be sent for it to be carried out. I do not include in this number those with temporary fibrillation. Glycosuria, corneal ulcer, or a severe grade of oedema had occurred in many cases. In others the restlessness had progressed to severe mental disorder. Because I have seen auricular fibrillation commence intermittently and become permanent, corneal ulceration occur, and mental derangement become more pronounced while patients are under treatment, I am compelled to believe that Dr. Barker's statement is not a true statement of the case.

I am not dealing now with the patients who are cured. I know as well as my medical colleagues how many are, and I know that if we were living in a modern Utopia instead of a rather hard modern world patients would not come to the condition I have described; but while we are all trying to eliminate the causes of the disease, we have to deal from time to time with a situation which is present.

End-results.

What evidence can we produce that surgical treatment will shorten the duration of the disease or restore to normal function organs which have shown evidence of failure?

I am not sure how much you will care to hear on this

Chart showing the urine output for three weeks in a patient with oedema and anasarca while under treatment with digitalis and diuretin, and the increase immediately following removal of part of the thyroid gland.

* Premature contraction in the last coil spontaneously; Q it disappears but recurs.

point; whether you would like a good deal of detailed evidence, or whether you would regard that as rather boring repetition. I have selected some photographs to illustrate different grades of the disease and the response to operative treatment in each.

First, two young women whom I place in the second class—that is, they had been ill more than six months, but had no heart failure—one of them earning her living by working in the General Post Office, the other with rather difficult home duties. The first went back to her work immediately on her return from convalescent home and has worked continuously for four years since. She feels quite well. The second, whose exophthalmos was such that she suffered from corneal ulcers both times she was in hospital, went home to nurse an invalid father who, apart from her day work, calls her out of bed several times every night. She states that she has not felt so well for many years. A fireman on the northern express service went back to his duties after his return from a convalescent home and has carried on continuously since. Two photographs were then shown to illustrate the disappearance of exophthalmos after operation.

Next we pass to patients in the third class—namely, with cardiac failure. These slides show electro-cardiograms of patients with permanent auricular fibrillation before operation and showing normal rhythm after operation. One of these, we believe, had had fibrillation for eight years, another for five years, so that it is difficult to believe that the fibrillation would have disappeared by means other than surgical. Leaving out those with temporary fibrillation, I operated upon eighteen with permanent fibrillation between 1921 and 1924, ten more during 1925, and four more this year, and of these almost all have regained normal rhythm. This is interesting in another respect. We do not yet know the origin of this disease, but the disappearance of fibrillation after operation shows that the origin of the toxins which cause some of the most distressing symptoms is in the diseased thyroid gland.

The accompanying chart (p. 559) illustrates the increase in the amount of urine immediately following operation in a waterlogged patient in whom diuretics had been ineffective. This patient arrived from South Africa as ill as a patient could be. Legs, thighs, and trunk were enormously distended; the abdomen and pleurae contained fluid; she was dyspnoeic, and the daily amount of urine passed was little over one pint; the heart had been irregular for five years. She was kept for a month while every effort was made to increase the urine, decrease the dropsy, and lessen her breathlessness. She was worse rather than better at the end of the month, and then one lobe was removed. You will see that in three days the urine output increased to 60 oz. and then to 90 oz. The oedema disappeared synchronously with this. Part of the second lobe was removed later. She went back to South Africa by herself. She now camps out, rides on horseback, and manages her household affairs.

One further aspect remains to be spoken of—namely, mental disorder. This complication is not common, but, taking a large number of cases, it is not infrequent. I could give instances of patients who suddenly became worse and died. I have had to decide what course to follow in eleven patients who were gradually getting worse and who were approaching, or had reached, a stage when they could not be managed in their own homes. I have never operated upon these patients without the fullest consultation, and without the relatives appreciating all that there was at stake. It is wise to have the help of a specialist in mental disorders before a decision is arrived at. Only one of these patients has not improved; the others have, after operation, returned to their ordinary way of living. One of them has married since, and one of the worst was driving her own car around London within eight weeks of her second operation.

The degree of recovery in these cases—and in the majority of cases—appears to be very high, and yet I think this is the appropriate place to say that I believe that in Graves's disease the secretion is not normal secretion, and that by reducing its amount by four-fifths we are not leaving a patient with an output of secretion normal in amount and quality, and therefore the end-results are not comparable with those obtained after removal of a diseased appendix. Patients who have suffered severely from exophthalmic goitre never become as normal as before the disease occurred, but they are a great deal nearer normal than if they had not been operated upon.

I would ask you to bear in mind two points. We must visualize a heart and nervous system flooded with toxic secretion, sometimes continued for years; if that toxic secretion is suddenly reduced by four-fifths the organs quickly show relief—often, indeed, dramatically—but it is unreasonable to expect that their complete recovery (their capacity to stand up to strain) should be other than gradual and may never be quite complete. My second point is, that from the time that a sufficient operation is performed the downward progress of the disease is arrested, the patient feels a different woman, and is on an upgrade all the time. She is conscious of this herself, and it is obvious to her friends.

THE TREATMENT OF GRAVES'S DISEASE BY LIGATION.

BY

LAMBERT ROGERS, F.R.C.S. Ed.,

ASSISTANT IN THE SURGICAL UNIT, WELSH NATIONAL SCHOOL OF MEDICINE,
ROYAL INFIRMARY, CARDIFF.

EARLY in the course of acute Graves's disease efforts should be made to abolish, or at least reduce, the thyrotoxicosis, prolonged exposure to which has been shown to result in definite myocardial degeneration. If after fair trial medical measures prove ineffective, more radical means should be adopted.

In my opinion both x-ray and radium therapy are undesirable, and the method of choice is partial extirpation of the overactive gland. The Mayos have emphasized the importance of performing this operation during one of the periods of remission, to which these patients are subject, but even then, in very severe cases, primary resection may prove a formidable and dangerous operation involving an unjustifiable risk, because the reaction may be great. However, by gradually cutting off the blood supply to the gland by ligation of its vessels, the degree of intoxication may be gradually reduced with but little reaction. It may then be advisable to perform partial thyroidectomy.

When the goitre is small, diffuse, very vascular, and exceedingly toxic, primary extirpation may be very dangerous, particularly in the presence of marked cardio-vascular disturbances. In such cases especially ligation appears to be the procedure of choice, and may be performed under local analgesia, which should be by novocain only, adrenaline being contraindicated.

Professor John Rogers of New York has recently advocated quadruple ligation in these cases, and in many has found it unnecessary to perform resection of gland substance later. Kocher pointed out the necessity of absolute hæmostasis in operations on exophthalmic goitre. Strict asepsis and rapidity of operating also largely contribute to success. With Crile of Cleveland, Ohio, the ligation of the superior thyroid artery is a most remarkable surgical feat, being at times accomplished in forty seconds, through an incision about one inch in length.

While some authorities maintain that the superior thyroid arteries are the more important, and from the point of view of comparative anatomy this may appear to be so, yet, as de Quervain points out, in goitre the changes in the thyroid occur principally in the middle and lower parts of the lateral lobes and are associated with increase in calibre of the inferior thyroid arteries, which form the principal blood supply to these areas. For this reason, and because the inferior vessels can be tied very easily in the way subsequently described, without handling or in any way disturbing the gland itself, which the surgeon should strive to avoid in highly toxic cases, it is often advisable in these bad cases to begin with ligation of one of the inferior thyroid arteries. However, it is undesirable to be dogmatic on this point; in one of my cases the largest vessel was the left superior thyroid, which was almost as large as the internal carotid. Moreover, it is only fair to point out that some authorities maintain that more good is done by ligation of the superior vessels because of the interference with the secretory nerve fibres which are said to enter the gland with these vessels.

Whichever vessel is first tied it is probably advisable next to ligate the other artery of the same side, because the anastomosis across the middle line has been shown to be less free than that between the upper and lower arteries of each lobe.

Most of the textbooks advocate tying the inferior thyroid artery through an incision which exposes the anterior border of the sterno-mastoid, but from first experimenting on the cadaver and subsequently from experience gained in practice I have found that a slight modification of the posterior route, popular with some Continental surgeons and recently advocated by Professor John Rogers, greatly facilitates the procedure. An incision about $1\frac{1}{2}$ inches long is made along the posterior border of the sterno-mastoid just above the clavicle. The muscle is retracted forwards, and on dissecting through the fasciæ the tendon of the

omo-hyoid is defined and pulled down downwards and forwards. In the angle between its upper margin and the inner border of the anterior scalene muscle, and behind and slightly external to the carotid sheath, the thyroid axis will be found, and from its direction upwards, inwards, and forwards towards the lower pole of the gland, the inferior thyroid artery is easily identified. The vessel is divided between ligatures. At this point it is the main trunk which is divided, and the division is well outside the recurrent nerve. There may appear to be a slight danger of wounding the cervical sympathetic, but this has not been found to occur in practice. No harm results from any damage, and, in fact, some authorities deliberately sever any fibres that appear in the wound.

The advantages of ligation of the inferior thyroid near its origin are that here one is well away from the recurrent nerve, and that there is little danger of either wounding the thyroid veins or of producing tetany by damaging branches to the parathyroids and so interfering with the collateral circulation to these bodies. The phrenic nerve lying on the scalenus anticus is not injured, as it is displaced laterally with the muscle.

Dietrich and Langenbeck, who, according to Crotti, were the first to advocate tying the vessel on the inner border of the scalene muscle, approached the artery between the two heads of the sterno-mastoid, while Drobnik, Rudiger, and Wölfler made their incision entirely behind the muscle. Alamartine says that ligation of the trunk of the inferior thyroid artery by the retro-sterno-mastoid route at the internal border of the scalenus anticus is the method of choice. Most of the ligations described, however, have been carried out below the tendon of the omo-hyoid; my slight modification is in approaching the vessel above the tendon.

The superior thyroid artery is exposed through the usual transverse incision at the level of the middle of the thyroid cartilage, and may be identified by tracing the vessel from one of its branches at the upper pole of the gland. The large veins leaving the upper pole may obscure the field and render ligation difficult. The loop of the artery should be looked for, as it lies on the inferior constrictor below the superior laryngeal nerve, but, as Kocher pointed out, it is sometimes necessary to free the external carotid and identify the artery by its origin.

Care should be taken to include in the ligature the posterior branch of the vessel, which sometimes arises high up and courses down the back of the gland. Severing what appears to be the main vessel between ligatures will enable the surgeon to see whether the posterior branch has been included or not.

The following is a brief history of a case of quadruple ligation.

The patient, a man aged 52, suffered from acute Graves's disease. Stellwag's and von Graefe's signs were positive. The pulse was 140 to 180, with occasional attacks of auricular fibrillation. Tremors were marked. The goitre was small, diffuse, and highly vascular. The patient was very emaciated and short of breath, and had been an invalid for many weeks. Three months before he had had to give up his work as a railway signalman.

Quadruple ligation was performed, one vessel at a time being tied under novocain analgesia; an interval of from ten to thirty days elapsed between each operation.

Subsequently there was great improvement. Ten weeks after the last ligation he had gained 29 lb. in weight, the pulse rate had fallen to 80, and there were no longer any tremors, but slight exophthalmos remained. He has since gained still more weight and returned to work, pulling heavy levers all day without discomfort. It is now nearly a year since his discharge from treatment; he has reported from time to time, and there have been no signs of tetany or cachexia strumipriva.

From such simple operative procedures involving little risk to the patient results of this type are very gratifying.

Quadruple ligation has now been performed very many times, and, contrary to what might be expected, deficiency symptoms following it are almost unknown. It is apparently very rare to meet with either tetany or myxoedema, and the explanation no doubt is that it is the trunks of the main thyroid arteries which are ligated, and that Neubauer's artery (the thyroidea ima) is a fairly constant vessel.

It is true that Kocher did not consider it permissible to tie all four arteries, because on one occasion on which this operation was performed by him his patient subsequently suffered from tetany; but this is probably accounted for

by the fact that his procedure was to tie the inferior thyroids close to or within the capsule of the gland. In 22 cases in which de Quervain tied the trunks of all four arteries no sign of tetany occurred subsequently.

At a later date it is hoped to supplement this paper with a detailed record of cases, but the object here has been to draw attention to the benefit of quadruple ligation in certain bad cases of exophthalmic goitre, and to put forward one or two points in technique with the hope that they may prove useful.

DENTAL SEPSIS AND SEPTICAEMIA.*

BY

E. M. BROCKBANK, M.D., F.R.C.P.,

HONORARY CONSULTING PHYSICIAN, ROYAL INFIRMARY, MANCHESTER.

ILLNESSES secondary to foci of infection situated about the roots of the teeth are known to be very common, but are apt to be overlooked. The infection may arise from: (1) An abscess at the roots of crowned or filled teeth which apparently are perfectly sound and causing no trouble whatever. (2) Nodular collections of organisms on the roots of the teeth. (3) Absorption of the alveolar process of the jaws, generally associated with more or less visible pyorrhoea, which leads to retraction of the gums and greater or less exposure of the roots of the teeth. (4) Tartar on the teeth.

Whenever a person is suffering from some illness of painful, debilitating, or infective nature for which no other cause can be found the teeth should be carefully examined. Visible pyorrhoea in small or profuse amount may be present, and swelling and inflammation of the gums and interdental papillae; or retraction of the gums may be very obvious. On the other hand, the teeth may be a picture of excellent crowning, bridging, or conservative filling work with healthy gums and yet harbour septic organisms.

It is therefore advisable to have all filled and crowned teeth or protruding teeth examined by x rays, because frequently it is by this means alone that serious septic lesions can be found. The films must be taken by an expert dentist or x-ray specialist used to dental film work; otherwise it is difficult to interpret the results accurately and unnecessary extraction may be done. Ill informed and inexperienced interpretation of x-ray films is responsible for much unnecessary extraction of teeth and disappointing after-results on the one hand, and for the overlooking of septic foci on the other.

The results of absorption of poison from infective teeth vary in an extraordinary way, and are in no way related to the extent of the dental sepsis. Some of the worst cases arise from small foci revealed only by x-ray examination; on the other hand, a marked degree of chronic purulent inflammation of the alveolar process of the jaws may be present, with visible pyorrhoea, teeth covered with tartar, and with foul breath, and yet the subjects enjoy rude health. Either these people's powers of resistance are perfect or the absorption of toxins is not so great where there is free escape of pus.

When septic absorption takes place the metastatic infection, whatever its nature, may run a definite course for a week or a few weeks and then clear up, Nature having produced efficient antibodies to neutralize the invading

toxins. There may be no return of bodily trouble for months or years. Then another outbreak of similar or different nature may occur. For instance, in one patient there was a violent painful inflammation of the tonsil like diphtheria which lasted ten days. Recovery took place, but in a year or so a severe acute painful neuritis and cramp affecting the nerves and muscles of the legs, especially of the feet, developed and lasted three weeks. X-ray examination showed extensive infection of the roots of the teeth, and wholesale removal has resulted in good health.

It is because of the use of x rays in investigating the condition of the teeth that more attention is being paid to general illnesses which can arise from dental sepsis than was paid ten years ago. I remember patients in private practice in my past experience, who had acute illnesses or who died, and in whom no satisfactory explanation of the toxic process was ever given. I often think of one man especially who had a virulent infection with a rash, which I took a fever specialist to see, and which was not scarlet fever. He died. I do remember that he had very bad teeth, but it was many years before the days of dental x-ray work. I do not refer to hospital cases in this paper.

There are two broad types of affections caused by sepsis of the teeth: one unaccompanied, and one accompanied by a rise of temperature.

1. *Apyrexic Affections.*—The common illnesses arising in this way are generally painful, such as myositis, fibrositis, neuritis, arthritis, or phlebitis. Affections of the stomach simulating ulceration and malignancy may, in my opinion, be caused by dental sepsis, and probably biliary infections as well. I always have the teeth of cases of indefinite gastric nature examined, and in many instances removal of septic teeth has relieved the complaint of the patient. A common type of apyrexic complication is an adult of 40 or more who has attacks of rheumatism or neuritis which affect any part of the body, come on at any time without exposure to wet or cold, but especially if the person is run down or overworked. The pain and stiffness may be very great, allowing lying down in only one stiff position to avoid pressure on the affected muscle or nerve, and causing a very crippled gait. Sleep without anodynes is impossible. If such a person has any septic teeth they are almost certain to be the cause of the trouble, and their removal will result in cessation of the pains, though, it may be, only after some months in long-standing cases. One interesting case I am watching now is a young gentleman farmer, aged 25, who has had three attacks of painful myositis, etc., affecting the neck and back, for which there was no cause like exposure to weather. He had an excellent set of his own teeth with only one filled molar. This we had x-rayed. The roots were not clear like those of the other teeth, and as it was a dead tooth it was removed, and definite evidence of sepsis about the roots was found. It is at present too early to say whether we have removed the cause of the "rheumatism."

2. *Pyrexial Affections.*—Among affections accompanied by a rise of temperature are inflammation of the throat, acute tonsillitis, arthritis, phlebitis, bronchopneumonia, and septicæmic conditions generally, including septic endocarditis. The temperature varies from a simple septic evening rise and morning fall lasting weeks or months to daily rigors of severe type lasting days or weeks or longer. In one case I will refer to it was more like rat-bite fever than any other condition I know of. In some cases it simulates that of irregular typhoid or paratyphoid infection, and Widal tests should be done to check diagnosis. Death has occurred in two cases in private practice under my observation.

PHYSICAL SIGNS AND SYMPTOMS.

Myasthenia Cordis.—One of the most important and commonest symptoms of dental toxæmia even in apyrexic cases is shortness of breath on slight effort—what I may call myasthenia cordis. This was the only complaint of one patient, and it had troubled him for many months. It may persist for several months after the offending teeth have been removed and the acute symptoms have passed off. There may be no evidence of dilated heart in these cases unless there is some associated anaemia; merely some inability on the part of the heart muscle to carry on the

* A paper read in opening a discussion on focal sepsis at the Manchester Pathological Society, December 9th, 1925.

circulation, and possibly the right side of the heart is more affected than the left because there is no oedema of the legs.

Lungs.—When the lungs are involved the condition is apparently a more or less extensive moistness or oedema not restricted to one part, with general crepitations varying in character and amount, and worse at the base. There is not much sputum. If the septic poisoning is extensive a widespread septic bronchopneumonia develops in one or both lungs, and death will probably result unless the teeth be removed.

Oral sepsis is one cause of delayed resolution in lobar pneumonia, and it may affect the course of the disease.

Nephritis in two of my cases began as albuminuria, followed by haematuria.

Phlebitis was a prominent complication in two of my cases, and directed my attention to the mouth. In one instance the man died of septic pneumonia; in the other the woman had a bronchopneumonia, which was a long time in clearing up.

An erythematous rash was a persistent complication in Miss Q.'s case; and it was present in the case I have already referred to which simulated scarlet fever. I have seen extensive erythema nodosum on legs and arms when the teeth were very septic.

Throat Affections.—Dental sepsis is a very common starting point for acute throat infections. Whenever there is a septic inflammation of the tonsils or pharynx which is not true diphtheria the condition of the teeth must be looked to. This is especially important in people who are subject to recurring throat trouble. Not only may there be a tonsillitis, but a profuse pharyngitis is common in dental sepsis.

Anaemia is sometimes a marked consequence of dental sepsis. The patient may look as if he were suffering from pernicious anaemia, but the anaemia is of the secondary type, with low colour index. I have never found extraction of teeth relieve true pernicious anaemia. Not uncommonly the teeth and gums are in a bad state in this disease, and removal is necessary as part treatment, but cure does not follow. I have not been able to get proper blood or bacteriological examination done in my cases. Many of them were seen in their own homes, and remote from such facilities. When I have had blood smears to examine there has been no definite departure from the normal in the number or characters of the leucocytes.

TREATMENT.

When obvious dental sepsis with inflamed and even bleeding gums is present in a case of septicaemia, and for which no other cause can be proved, the teeth should be extracted. Generally there is only a reduced number of teeth present, and they can all be extracted with safety. Bleeding is not likely to be as troublesome when many teeth are removed as it is for a single tooth or two teeth, the shock to the peripheral vasomotor system being so great that the arteries contract. The shock of extraction in all my cases has been very little; what bleeding has taken place has done good, and the temperature has soon come down to normal. I have had several infected teeth removed when there has been bronchopneumonia present. A skilled dentist will take only a few minutes to remove many teeth, and the anaesthetic for this time has so far done no harm in my cases with pulmonary complications. If most of the teeth are still in the mouth the worst half could be removed at one time and the rest cleaned with

carbolized dental pumice-stone powder and the gums painted with half-strength tincture of iodine daily. This cleans up a mouth very much, but will not remove the deep-seated sepsis.

Cases with No Visible Sepsis.

CASE I.

Mr. X., aged 50, in September, 1923, had a rigor followed by acute pneumonia of septic bronchopneumonia type. Empyema developed from a virulent streptococcal infection. One week after the empyema operation he had nausea, his feet swelled, and the urine contained albumin and blood with streptococci and *Bacillus coli*. The nephritis lasted until Christmas, 1923, when he got up for the first time. Before getting up the temperature was normal; but his pulse rate kept at 120, rarely below 100. In May, 1924,

his pulse was still fast and he was easily short of breath, but he felt better and resumed work in June. For seven weeks he felt comparatively well, then he began to suffer from appalling headaches and had to go to bed. The temperature was only 99°. Then intense soreness and swelling at the head of the radius bone came on rapidly like an acute inflammation of a joint. His temperature was then rising to 102° at night; he also had pains in his back and right shoulder, which lasted three days and kept him on his back. The elbow-joint pain passed off without any pus forming.

In October, 1924, x-ray examinations showed that there was no collection of pus in the chest. I found, however, that he had two old filled left molar teeth which had never given him any trouble. X-ray examinations showed abscesses at three of the four roots. The teeth were extracted and there was a reaction of temperature in twenty-four hours to 102°, and other slight reactions until a spicule of necrosed bone came away from the seat of extraction. The temperature then settled down and he gradually got back to his former health, but only after a period of eight months.

CASE II.

Miss Q., aged 28, was seen in March, 1925. For weeks before she had had severe pains all over, and in most of the joints, especially in the knees and ankles. There were daily rigors with temperature of 105°. She had an erythematous rash over the body as well. There was no obvious cause of the rigors, but the mouth was full of crowned teeth. These teeth were removed and the subsequent history is very striking. Her doctor writes:

"Miss Q. made a good recovery, though only after seven months' illness. For a month after the teeth were extracted she continued to have a daily rigor and high temperature, usually 105° or thereabout. On one occasion it reached 107° (taken by her mother).

"After a more severe attack of headache and sickness than usual the attacks came every second day, the temperature reaching between 103° and 104°, with very little headache and great improvement in the general state. This periodicity lasted about eight weeks. Then the attacks came every day (temperature about 102°) for six weeks up to the end of August. During September the attacks came mostly every second day (occasionally on the third). In the early part of October they came every third day. In the second week of October she had a very severe attack with violent headache, sickness, and prostration, the temperature reaching 104°; the next day she was fairly well, and on the day following that a slight attack—temperature 101°. Since then (the middle of October) there has been no fever and she has felt quite well. With every febrile attack she had a renewal of erythema, chiefly blotches; sometimes nodes on the arms, and pains in the joints, chiefly the ankles. Her mother and herself are quite certain that she had attacks of the same kind as in this illness, though much slighter, at intervals during the last two years. During this time they recollect her having red blotches on the lower part of the neck."

The dentist reported that there was some pus in the pulp cavity of one or two of the teeth; only in one tooth was there any trouble at the apex, and that only beginning.

CASE III.

Mr. E., aged 26, was well until three years ago. He had diphtheria in 1924. In June, 1925, he had swelling and pain in the glands in the neck below and behind the right ear. Temperature 102°. As the pain and swelling persisted the glands were opened; no pus came away, but only a brown thin discharge. Two days afterwards marked albuminuria developed, and in another day haematuria. Temperature of septic type with evening

Type of temperature. Widal test negative.

Type of temperature for weeks.

rise to 101.5° or 102° continued. I saw him six weeks after the onset of the adenitis. On examination it was found that he had five or six molar and bicuspid teeth which had been filled for five years, and when asked if they had caused trouble, said "No, except that two of them became tender on the day of the operation." The teeth were examined by x rays and absorption of the roots of those which had caused pain at the time of the operation was found. The other teeth were indistinct and suggested absorption. All doubtful ones were extracted and the patient has improved steadily since. The diphtheria may have been a septic condition secondary to focal sepsis.

Cases with Visible Sepsis.

CASE IV.

Mr. F., aged 45, for three weeks in 1923 had felt very ill and unable to carry out his work as a baker, although he did not go to bed. His temperature was rising to 101° and 103° at night; he had incontinence twice, and on one occasion had a kind of fit. The mouth was very foul, the gums being inflamed and bleeding easily. Although seriously ill (it was felt that he was dying) all the teeth were extracted. He recovered after this and has been quite well since. He was said to have had a similar illness sixteen or seventeen years ago, from which he recovered. This I believe to have been a slighter attack arising from similar though less virulent dental sepsis.

CASE V.

Mrs. C., aged 67, had pneumonia in March, 1924; it was apparently lobar pneumonia of the left base. This cleared up very slowly and three months later she developed oedema of the left leg. The temperature had been normal for a few weeks, but began to rise again three weeks before I saw her the second time. The mouth was very foul with septic incisors and canines. She had not visited a dentist for twenty years. The teeth were dealt with as soon as possible and she gradually got back her usual health.

CASE VI.

Mr. J., aged 49, was seen in November, 1925. In July he had an attack of "influenza" with high temperature but with no physical signs. Since then he was constantly short of breath, which varied in degree, and he found all stairs trying. A few days before I saw him he had a similar attack of feverishness. His temperature rose to 102° in the evening; the spleen was palpable, the W.B.C. test negative. A few moist sounds were heard over the bases of the lungs, especially the left lung. He had had a cough in recent winters. There were no teeth in the upper jaw, but eight or ten in the lower jaw were in a very septic state and he had pharyngitis. He was too ill to do anything, and he died in a few days of septic intoxication and bronchopneumonia.

CASE VII.

Mr. E., aged 47. This man's illness began with phlebitis and oedema in the left leg, which lasted ten days and was clearing up when the right leg became involved. I saw him at this time, and, looking for a cause, found a very offensive condition of the mouth, pus exuding from round all the teeth and stumps and spongy inflamed gums. The man was so ill that immediate treatment was thought necessary, and he was removed to hospital for it. He died, however, of septic pneumonia in thirty-six hours, and before the teeth could be dealt with.

CASE VIII.

Mr. K., aged 34, felt so debilitated that it was feared that he might have pulmonary tuberculosis, which was in the family. I could find no sign of organic disease anywhere. In the mouth he had five very fine specimens of crowned teeth which had been there for five years and had caused no trouble. X-ray examination showed seven teeth to be diseased at the roots. They were removed, and progress to usual health followed—slowly, as it does in most cases of dental sepsis.

CASE IX.

Mr. A., aged 54, complained of palpitation and shortness of breath on very slight effort and of easily getting tired. He was definitely anaemic and a blood count showed red blood cells nearly normal (4,700,000), colour index 0.8 only; no special changes in the white cells. He had some slight dilatation of the heart. His teeth looked very suspicious; there was a protrusion from the gums, but there was no marked pyorrhoea. X-ray examinations showed that there was a great deal of deep-seated sepsis. After necessary extractions by his dentist he began to feel better and soon got perfectly well.

CASE X.

Mr. M., aged 40, underwent operation for gall stones in November, 1925. Three weeks later double quinsy developed, with thirst, polyuria, and glycosuria; insulin was given. On December 7th bronchopneumonia affecting the bases of both lungs supervened, with pink sputum, a temperature rising to 103.5°, and an occasional rigor; he was very delirious at night. The teeth and gums were very septic; removal of the teeth was advised, and done the next day (December 12th), though he was extremely ill. Improvement followed almost at once, and recovery in a few weeks with no glycosuria.

I could give notes of other similar cases in private work and many from hospital practice.

DENTAL CONDITIONS LIKELY TO FORM SOURCES OF INFECTION.*

BY

BARRON J. RODWAY, O.B.E., L.D.S.R.C.S.ENG.,
HONORARY DENTAL SURGEON, ROYAL INFIRMARY, MANCHESTER.

WHEN discussing dental disease as a factor in the causation of general disease, it is difficult for a dentist to be definite in his statements. He frequently sees a patient who has been under medical treatment for an ailment for some time without sufficiently good results following, and he finds a condition of oral sepsis present. He treats this, the patient begins to improve, and he rather naturally is inclined to conclude that the removal of the oral sepsis has been the dominating factor in the successful treatment of the case. He also wonders if the oral condition was not also the dominating factor in the causation of the disease. As the patient in all these cases has been receiving medical treatment at the same time, he can only wonder—he cannot definitely claim that the treatment of the oral condition cured the general condition. But when he sees this happen time after time he necessarily concludes that there must be a probability that oral sepsis is a common predisposing cause of many ailments.

As I am therefore not able to make any definite statements as to the relationship between oral sepsis and the many diseases which may be influenced by it, I will confine myself to a description of the dental conditions which are most likely to influence the general health, and will indicate how x-ray examination of the teeth helps in the estimation of the likelihood of the teeth, in individual cases, forming foci of infection.

It appears to me that there are three broad classes of oral conditions which may result in general septic infection. In the recent discussion at Bath there seemed to be a disposition to regard only two classes—an open and a closed form; the open form being harmful from the effect of the swallowing of the organisms and their toxins, and the closed form from the absorption of the toxins through the blood stream via the bone. To me this seems a little misleading, as the condition of pyorrhoea is almost surely a combination of the two forms; hence my description of three types.

The first type is that in which sepsis is solely the result of neglect and lack of use of the teeth, where the teeth, at their gingival margins, are covered with deposits of salivary tartar and debris. There is generally a gingivitis present resulting entirely from the presence of these deposits, but the gums do not present, except just at the gingival margins, the congested appearance which is characteristic of pyorrhoea. This condition can generally be rapidly cleared up by careful attention to scaling and cleaning of the teeth. In this class of case, although there may be a certain amount of infection through the capillaries from the gingivitis, the chief ill effect is caused by the constant swallowing, both in the saliva and in the contaminated food, of the organisms and their products. The appearance of the mouth (in this type of unhealthy mouth) is often more striking than that of either of the other two types, but the condition is not nearly so harmful as regards infection.

The second type is that in which there are non-vital teeth present—that is, teeth whose pulps have been destroyed either in the process of preservation of the teeth, or through the progress of caries. Although very many teeth are successfully treated by devitalization of the pulp, with its subsequent removal and replacement by filling material, there are unfortunately many teeth whose pulp canals are beyond the skill of the average dentist to fill completely. In these latter cases, and in cases where the pulp has become necrotic as the result of caries extending to the pulp chamber, there is a possibility of the sepsis present extending through the foramen in the apex of the root, and causing an area of necrosis to develop in the vicinity. These areas are shown in x-ray films of the teeth as dark shadows round the apices of the roots of the

* A contribution to a discussion on focal sepsis at the Manchester Pathological Society, December 9th, 1925.

teeth, due to the presence of the resulting cavity in the bone of the jaw. The character of the walls of the cavity as shown in the film quite frequently gives an indication of the rate of progress of the bone destruction. Any toxins which may be formed in these areas are necessarily conveyed directly into the lymphatic system, as the region is completely shut off from the mouth.

The third type is that in which the condition commonly known as pyorrhoea is present. The subject of pyorrhoea, or chronic general periodontitis, is so large a one that I am not now in any way attempting to deal with it. Its symptoms are well known. After a preliminary gingivitis the gums become puffy and congested in appearance. The periodontal membrane begins to ulcerate and to break down, and then the edges of the bone become necrotic. The gum margins readily bleed and pus can generally be expressed from the edges.

There is a condition of acute gingivitis, very similar to the trench mouth condition seen so much during the war, which one sees frequently nowadays, and which is commonly incorrectly diagnosed as pyorrhoea; it is a condition which is amenable to treatment, but the slowly progressive general periodontitis, the true pyorrhoea, is generally so firmly established when it is first seen that the bone is already well infected, and nothing short of the loss of the teeth and the resulting absorption of the alveolus will cure the disease. I am pretty firmly convinced that only in its earliest stages is real chronic general periodontitis curable without loss of the teeth.

Having thus briefly described the three types of dental conditions which are likely to form sources of infection, I would like to emphasize the reason why such a source may be so injurious as it probably is. To do this I would point out that the most serious infection from the mouth takes place through the periodontal membrane and its surrounding tissues. It has been demonstrated, quite conclusively I think, that there is a very complete network of lymph capillaries extending through the slender papillae at the margins of the gums which accompany the blood vessels and nerves through the connective tissues into the spaces in the bone. This being so, it is easy to see how toxic substances are conveyed from the infected gums to the lymph glands and thence to the blood stream.

The extent of the periodontal membrane is not always appreciated. If the membrane is stripped off, say, the central incisor tooth and is flattened out, it will form a triangle whose sides will measure roughly three-quarters of an inch. If this triangle is multiplied even twenty times, allowing for the previous loss of a dozen teeth, a surface as large as the palm of the hand will be covered. An ulcerating surface of this size is quite a serious matter, especially when it is remembered that the ulceration is taking place in an area from which there is little external drainage.

By means of x-ray films it is possible to form a good idea of the probability of the existence of infection from the teeth and the alveolar margins. In the normal mouth the gingival trough, which is the small depression which surrounds each tooth at the margin of the gum, is covered completely with a layer of epithelium which shuts off entirely the periodontal membrane from any contamination from the fluids of the mouth. If, from any cause, this epithelial covering is destroyed, there is no longer any protection for the periodontal membrane from the action of the organisms present in the mouth. The membrane has very little power of resistance, and the organisms soon spread deeply into the tissues, including the bone, which gradually break down. Any cause of chronic irritation may account for the destruction of the epithelium of the gingival trough, especially any cause which results in a food stagnation area being formed. Such an area may result from irregularities of the teeth, the edges of overlapping fillings or crowns, improper diet, insufficient cleaning, etc.

Dental x-ray films show quite clearly when the cortical layer of the bone of the tooth socket is beginning to break down, and the extent of the bone destruction in any individual case can be readily seen. The films also show quite clearly when there are areas of necrosis around the apices of the roots of the teeth.

In cases of general illness, where a physician or surgeon has decided that the disease is probably one of infective origin, or is one which is being maintained on account of the presence of some septic focus, if dental x-ray examination shows a probability of the presence of bone destruction, either from infection of the periodontal membrane or from the presence of non-vital teeth causing necrotic areas in the bone, then the question of the advisability of removing the teeth affected has to be considered, and the question which perplexes is, How big a sacrifice in the way of removal of the teeth is justifiable in the hope that a good general result will follow?

There is no doubt that frequently all the teeth are removed for a patient and he finds that little, if any, improvement in his general health follows; but my own experience leads me to think that very much more frequently a big improvement follows.

When discussing the subject with the patient my practice is to point out that while treatment of the dental condition might be too late to overcome the harmful effects which have been accruing for years, it might reduce them to some extent, and would almost surely check the progress of the general disease. In order to avoid subsequent disappointment the patient is at the same time made to understand that artificial dentures are at the best only poor substitutes for a natural dentition, but that they can in most instances be made sufficiently efficient to deal with a selected diet. The extent of the dental extraction operation is too big a subject to deal with in a few words, but one fact is certain—if dentures have to be worn, no teeth must be allowed to remain which are not soundly implanted in healthy bone and surrounded by firm and healthy soft tissues. The wearing of an artificial denture on gums which are at all likely to suffer from gingivitis will speedily set up the condition.

OBSTRUCTION OF SMALL INTESTINE BY GALL STONES.

A SERIES OF THREE CASES WITHOUT MORTALITY.

BY

CHARLES BENNETT, M.B.,

ASSISTANT SURGEON, WESTERN INFIRMARY; SURGEON, OUT-PATIENT
DEPARTMENT, ROYAL HOSPITAL FOR SICK CHILDREN, GLASGOW.

THE discussion on intestinal obstruction at the last Annual Meeting of the British Medical Association¹ brought out, among other interesting matters, some remarkable facts and statistics concerning obstruction due to gall-stone impaction.

The number of such cases tabulated compared with the total number of cases due to all causes is insignificant: 28 to 3,064, an astonishing proportion. These 28 cases, moreover, occurred over a period of years in the practice of seven large hospitals. The incidence works out at less than one per annum per hospital. The condition must, therefore, be regarded as extremely rare, especially in the experience of any single individual. Not less remarkable than the rarity is the high mortality: of the 28 cases no fewer than 14 died.

In connexion with the discussion the cases reported below have peculiar interest. All three passed through my hands within the space of eight years, and, contrary to probabilities from the statistics above, all recovered. I have endeavoured to bring out the main points of the cases in accordance with the analysis used in the discussion at the Annual Meeting.

CASE I.

A married woman, aged 68, on May 8th, 1925, was admitted to ward 31 (Mr. G. H. Edmondson's) Western Infirmary, Glasgow, suffering from acute intestinal obstruction, with vomiting of forty-eight hours' duration. There had been no movement of the bowel for three days. Signs of acute intestinal obstruction were unmistakable. For three years this patient had suffered periodically from pain after food, and flatulence, but there had never been jaundice.

I operated about two hours after her admission, and extracted a gall stone from the ileum twenty inches proximal to the ileo-caecal valve. The patient made a good recovery. The stone was roughly spherical, 1 inch in diameter, and the dry weight was 140 grains.

CASE II.

On June 9th, 1924, I was called in consultation by Dr. E. R. Weir of Dunoon to see an unmarried woman, aged 68, who had been suffering from abdominal pain and vomiting for forty-eight hours. The signs of acute intestinal obstruction were complete, but the vomit was not faecal.

Operation was immediately undertaken. On inserting a hand into the abdomen I came at once upon a mass in the ileum four or five inches proximal to the ileo-caecal valve. Through a small incision in the bowel I removed a gall stone. Recovery was uneventful.

This calculus was roughly a truncated cone. The greatest length equalled the greatest breadth—namely, one and one-fifth inches. The dry weight was 180 grains.

CASE III.

A detailed account of this case has already been published in another connexion.² The operation took place on January 10th, 1917. A married woman, aged 52, had had a long experience of so-called gastric disease before intestinal obstruction manifested itself. The stone which I removed from the ileum was ovoid in shape, the greatest circumference being $5\frac{1}{2}$ inches, and the weight was 636 grains. Recovery was uninterrupted.

I saw this patient recently, more than eight years after operation, when she reported well, and stated that she had had no recurrence of discomfort.

It is noteworthy how seldom these patients have earlier symptoms pointing directly to the gall bladder; that there should sometimes be complete absence of any morbid signs before the onset of obstruction is equally striking.

It is scarcely ever possible to diagnose the cause of the obstruction before operation, but during the operation the mass in the intestine is easily discovered by the exploring hand. The bowel, tightly gripping the impacted stone, shows signs of bruising by the irregular surface of the calculus, and the direction of the incision into the intestine must be determined by the injury already sustained by the intestinal coats.

On no occasion have I attempted, as advised by several authorities, to move the stone along the interior of the bowel before cutting down upon it, as I am of opinion that the less the damaged intestine is handled the better.

It is now generally believed that gall bladder and small intestine adhere together on account of an inflammatory process, and that the large calculi pass directly into the intestine through a stoma set up by a process of ulceration.

There can be little doubt that these patients, when they have recovered from the operation for intestinal obstruction, derive considerable benefit from the cholecyst-enterostomy established by this curious happening. By this means they become possessed of two outlets from the gall bladder, and a period is thereby put to this organ acting as a factory of gall stones.

TUBERCULOSIS IMMUNIZATION.

BY

NATHAN RAW, C.M.G., M.D., M.R.C.P.LOND.,
LORD CHANCELLOR'S VISITOR IN LUXAC.

IN the BRITISH MEDICAL JOURNAL of July 19th, 1924 (p. 102), I described a series of animal experiments in which it was conclusively shown that it is possible to give active immunization to animals against a virulent dose of tubercle bacilli.

A further series of experiments has just been concluded at the Lister Institute with the same encouraging results, and I am hopeful that in the near future the work will be extended to young children, with a view to protecting those who are in daily contact with cases of open tuberculosis.

Animal Experiments.

A large series of rabbits and guinea-pigs were used. Half of the animals were given protective doses of vaccine prepared from attenuated killed human bacilli, which had been continuously subcultured by me for sixteen years, and were quite non-pathogenic and non-tuberculo-genic. Two protective doses were given—one on July 25th, 1925, and

the other on August 1st. The whole series of animals, including the controls, were then given 0.1 mg. of virulent bovine bacilli by Dr. Schutze.

One of the rabbits and two guinea-pigs died in three weeks from septicaemia, and the whole of the controls died within three months of acute and generalized tuberculosis. The protected animals gained weight and appeared quite healthy when they were killed on February 24th, 1926. A very careful post-mortem examination of the rabbits was made by Dr. Schutze and myself. The animals were fat and in excellent condition. At the site of inoculation (in each case in the thigh) was an enlarged gland or glands, but not extending into the inguinal glands. There was no trace of tubercle in any of the organs. Smears from the glands showed tubercle bacilli in large numbers, and these will be injected into guinea-pigs with a view to testing their virulence. It is evident that a local infection was produced at the site of inoculation, but the animals were protected against a progressive tuberculosis.

As my previous experiments have also shown, it is only possible to protect animals by using bacilli of human origin, against an infecting dose of bovine origin, and vice versa.

Conclusions.

The problem of tuberculosis resolves itself into the question of immunity. Contrary to what is observed in other infectious diseases, no immunity is conferred on the human by a previous attack of tuberculosis, caused by the same type of bacilli. Pulmonary tuberculosis, which is nearly always caused by bacilli of the human type, does not appear to give immunity in after-life, and patients whose disease has been arrested are liable after many years to another acute attack of active tuberculosis. Clinical experience, however, goes to show that children and young adults who have received a mild infection of bovine bacilli in milk, causing enlarged glands in the neck, bone and joint lesions, and other forms of localized tuberculosis, are practically immune to pulmonary tuberculosis, and it was this observation that led me to use bovine bacilli to immunize animals and man against the more serious disease of the lungs.

It seems to be probable that children may be protected against infection in the household, but some years must elapse before this can be finally established. All children over the age of 1 year who are living in the same house with a tuberculous member of the family ought to be protected if possible against infection, and it is in the early years of life that such infection usually occurs.

From a long observation of tuberculosis I am convinced that if some active immunity can with complete safety be given to those children who are directly exposed to infection at home, a long step will have been taken in the direction of prevention, which, after all, is the key to the problem.

The protection of the community by some safe scientific method of active immunization is the only effective way by which this preventable scourge can be eradicated.

FRACTURE OF THE SKULL AND EXTRADURAL HAEMORRHAGE WITH SYMPTOMS OF HYPOTENSION.

BY

SYDNEY SMITH, M.D., D.P.H.,

PRINCIPAL MEDICO-LEGAL EXPERT, EGYPTIAN GOVERNMENT SERVICE.

THE case recorded below is of much interest, since, although there was considerable extradural haemorrhage, there was a complete absence of pressure signs. The case suggests that a haemorrhage within the skull may act not only, by its own local pressure but also by its general effect on the pressure of the cerebro-spinal fluid of the brain.

A man, aged 26, was knocked down by a tram on November 27th and was taken to hospital in a comatose condition. On admission the pulse was 100 and irregular, the temperature 38°C ., and the respirations shallow. There was escape of blood from the nose and the right ear. The pupils were unequal and

fixed. The conjunctival reflexes were present, but all the deep reflexes were absent.

A lumbar puncture showed the cerebro-spinal fluid to be blood-stained and under tension. Subsequent lumbar punctures on November 28th, 29th, and 30th showed progressive diminution in pressure, and on the 30th the pressure was much below normal. The general condition of the patient did not materially alter for a few days, but on December 5th (nine days after the injury) he spoke, and was able to brush the flies away from his face. On December 6th and 7th he appeared to improve steadily as regards consciousness and muscular power, but the pulse continued rather feeble and rapid (110-112). On December 8th the pulse was 116 a minute and very feeble, and the respirations 40. At this time the blood pressure was 110 mm. and the pupils equal and reactive.

After recovery from the initial shock the patient showed general signs of cerebral irritation but none of pressure. From December 8th to 11th he remained in the same condition of partial consciousness; there was no sign of paralysis, but the pulse became progressively weaker and more rapid, and he died on December 11th—fourteen days after the injury.

At the post-mortem examination the following conditions were observed:

There was a lacerated injury about the size of a florin on the right parietal eminence of the skull which reached the bone and around which there was considerable infiltration of the tissues with blood. There was a fissured fracture of the skull under this injury which ran from the vault in two portions—one along the right petrous temporal through the sella turcica into the left middle fossa, the other forwards to the posterior wall of the right orbit. The fractures crossed both anterior and posterior branches of the right middle meningeal artery, and an extradural haemorrhage was caused by rupture of the posterior branch. This haemorrhage formed a clot, 7 cm. in diameter, beneath the above-mentioned injury, and the clotted blood, though not extensive, was sufficient to cause flattening of the convolutions of the brain beneath it.

On the base of the skull there was a quantity of clotted blood along the line of the fractures, and a certain amount of pressure must have been caused on the emerging nerves and on the pituitary body.

There was no injury to the brain substance of the right hemisphere except a small bruise over the right middle temporal gyrus.

On the left side of the brain the pia arachnoid showed a generalized diffuse blood staining, but no definite extravasated blood could be made out. There were, however, several lacerations of the left cerebral cortex—one over the inferior frontal gyrus near the frontal pole, a second on the middle frontal 5 cm. from the pole, and a third more extensive bruised area above and parallel with the posterior ramus of the Sylvian fissure affecting also the superior temporal gyrus in its anterior part and the orbital surface of the inferior frontal gyrus near the temporal pole. This bruise covered an area 4.5 by 3 cm., and passed through the grey matter into the white substance. There was also a bruise of the middle and inferior temporal gyri, extending from the temporal pole for a distance of 3.5 cm. On replacing the brain inside the skull cap the lacerations were observed to be roughly opposite the site of the injury if a line were drawn from this site through the central point of the skull. They were, however, dispersed over a considerable area, and in the writer's experience these contre-coup lesions are usually found over the poles of the brain whatever be the site of the violence.

The absence of any sign of pressure in this case is of considerable interest, for the extradural haemorrhage was sufficient to cause flattening of the brain convolutions, and, therefore, should have produced definite pressure effects. The diminished cerebro-spinal pressure is a feature which possibly explains the absence of pressure signs. Leriche has described a definite syndrome caused by diminished tension in the cerebro-spinal system with symptoms of torpor, mental stupor, or sometimes coma. There is no paralysis or contraction; the pupils are normal, and the reflexes positive. Stultz and Stricker¹ have caused an increase in the cerebro-spinal tension in these cases by the injection of 40 c.cm. of distilled water into a vein, which resulted in an almost immediate increase in tension and remission of symptoms.

In the case under review it is possible that the lesion of the pituitary may have caused hypotension of the cerebro-spinal fluid, which entirely obscured all focal symptoms of the extradural haemorrhage, and gave rise to the symptoms described by Leriche as those caused by diminution of the tension of the cerebro-spinal fluid.

In such cases—and they are probably not uncommon—it is possible that intravenous injection of 30 to 40 c.cm. of distilled water might not only cause a remission of the symptoms due to hypotension, but the increased cerebro-spinal tension would then allow the haematoma to produce symptoms which would lead to its localization and treatment.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

INJECTIONS OF ACRIFLAVINE FOR TUBERCULOSIS.

SINCE its introduction I have used acriflavine in every kind of case in which an antiseptic is indicated, because of its bactericidal properties and its non-toxic effect on the tissues. For the latter reason I was tempted to try, somewhat empirically, the effect of hypodermic administration of the drug in cases of advanced pulmonary tuberculosis. The results obtained exceeded my expectations, and I feel that a trial by others is warranted. Three cases only have been treated in this way.

CASE I.

A young woman, aged 24, with advanced phthisis of three years' duration, had on two occasions received sanatorium treatment, and was discharged the second time with the report that further sanatorium treatment was useless. After two or three injections of acriflavine the patient felt much better. Within a month the physical signs markedly improved—the fever was reduced, night sweats ceased, sputum decreased and became less purulent, and the moist sounds in the lungs cleared up. For nine months before the first injection she was confined to bed, and now, after five months' treatment, she is able to walk two miles daily without fatigue. The report on the last examination of sputum states that "the tubercle bacilli are not very numerous, about one per two fields." The first dose given was 5 minims of 1 in 1,000 solution of acriflavine in normal saline, and three doses were given at intervals of forty-eight hours. There being no local or general reaction, the amount was doubled and given at the same intervals. As still no contraindications were observed, the dose was rapidly increased to 40 minims twice a week.

CASE II.

A youth, aged 21, with Pott's disease of long duration, was treated in exactly the same way. Here again the improvement is definite, though of not so dramatic a nature.

CASE III.

This is an instance of advanced tuberculosis of the pleurae and lungs in a man aged 32, who (except during two short periods of sanatorium treatment) has been under the constant observation of my partner for four years. For the last year he has been a complete invalid, and for several weeks immediately preceding the treatment he had been confined to his bed by pronounced hectic fever with a daily rise of temperature to 102° or 103°. An application for further sanatorium treatment had recently been refused (after examination of the patient) on the ground of the hopelessness of the case.

After initial smaller doses beginning on December 9th, 1925, this patient has, from December 22nd, been given 25 minims of the solution of acriflavine every fourth day. From the commencement of these injections, except during an attack of coryza lasting four days, the daily maximum temperature has been 99.2° or less; night sweats have ceased, coughing is much less, and the quantity of sputum has diminished to one-tenth of its former amount. Tubercle bacilli are still present, but the sputum is now mucoid rather than purulent in character. The patient has left his bed during the last six weeks and is now able to walk a mile or so daily.

My colleague, while reserving judgement as to the value of acriflavine treatment, states that in a long experience he has never seen so manifest an improvement in an advanced case of phthisis.

How the drug works can only be a matter of conjecture, and I would welcome the opportunity of trying it in a larger number of cases, but I have not felt it justifiable to retain patients in the early stages of tuberculosis when sanatorium treatment is available.

I hope these notes will arouse sufficient interest in others who have the opportunity of treating the disease in its early stages.

Romsey, Hants.

G. H. JOHNSON, M.R.C.S.

PARATYPHOID A FEVER IN SCOTLAND.

THE following two coincident cases of paratyphoid A fever are of interest owing to the infrequency of this type of the enteric group in Scotland.

According to Goodall, paratyphoid A fever was not found in Europe before the great war, but was known to occur in Asia, especially in India. Paratyphoid B, on the other hand, was occasionally found in Europe but not in Asia.

The patients were two brothers, one of whom, aged 9, became ill on January 20th, 1926, with general malaise. His temperature was 102°, rising to 104° in the evening. There followed an afternoon rise of temperature for some days, fluctuating between 100° and 102°, on one day 104°. Constipation was marked throughout, with abdominal uneasiness and slight epigastric tenderness.

The lungs were clear. On January 26th epistaxis occurred, and on the 27th Dr. Marion Watson of the Johnstone Combination Hospital did the agglutination test, which proved positive to *B. paratyphosus* A and negative to *B. typhosus* and to *B. paratyphosus* B. The temperature came down by lysis and has been normal since February 5th.

The patient's brother, aged 12, left for boarding-school on January 19th. The next day he had a headache. He was isolated as a measles suspect. He had a slight rise of temperature for ten days, which latterly rose in the evenings. He was motored home on January 30th. A blood test at the Royal Infirmary, Glasgow, proved positive to *B. paratyphosus* A. He has since been apparently well with normal temperature.

Both patients spent two days at Craik (January 1st and 2nd) and had a meal in Glasgow on January 11th and 14th.

CYSTIC DILATATION OF URETER: REMOVAL OF URETERIC CALCULUS PER VAGINAM.

NEPHRECTOMY alone will not cure the cause be also dealt with. The this.

A woman, aged 49, was admitted to the Royal Victoria and West Hants Hospital, Bournemouth, on January 26th, 1926, complaining of a painful swelling in the left abdomen. This had been noticed for a year, but beyond occasional frequency of micturition there were no other symptoms. Twenty-four years previously her left kidney had been removed for what appears to have been a hydronephrosis.

On abdominal examination a smooth oval swelling, moderately movable from side to side but not from above downwards, tense, and dull to percussion, was found in the left lumbar region. A stalk proceeded from its lower pole to the pelvic cavity. By the vagina considerable induration of the cellular tissues could be felt in the left half of the pelvis; the genital organs were normal. The urine was acid, sp. gr. 1018, no albumin, no renal casts or tubercle bacilli.

First Operation.—On January 27th Mr. Belben operated. A left paramedian incision was made. No kidney was present on the left side, but a retroperitoneal cystic sausage-shaped tumour (about 5 by 2 in.) with a dilated duct (about 1½ in. across) passing downwards to the pelvic cavity occupied the usual position of the kidney and ureter. The cyst and upper part of the duct were removed, but the lower part was so buried in adhesions involving the iliac vessels that it was thought best to drain it. On February 22nd the wound was dry and healed. X-ray examination revealed a large oval shadow in the left side of the pelvis (? calculus, or calcified gland).

Second Operation.—Mr. Belben operated again on February 24th. The left vault of the vagina was incised and an oval calculus (about 1½ by 1/2 in.) was removed from the lower end of the left ureter. Some pus escaped but no urine. The wound was loosely stitched. There was a mild discharge which necessitated daily douching; this is now diminishing, and there is complete urinary control.

Pathological Report on Cyst.—The walls are lined by columnar epithelium. The cavity is filled by a dark fluid containing albumin, pus cells, blood, and mucin, but no urea.

I wish to thank Mr. Belben for permission to publish this case.

I. ATKIN, M.B., B.S.Lond.,
House-Surgeon, Royal Victoria and West
Hants Hospital, Bournemouth.

SAC OF CERVIX WITH RETAINED MENSES.

A PERSIAN woman, aged 26, consulted me for abnormal menses with intense pain. She had never menstruated normally, but every month had very bad pelvic pain and slight oozing of brownish fluid from the vagina. There was an indefinite history of vaginal discharge in youth. On examination there was an apparently closed vagina and neither cervix nor uterus could be felt, but, per rectum, a tumour could be defined high up, which it was thought might be the uterus. The patient begged for operation as, unless she was proved to have normal organs, she would be divorced.

I operated, opening in the mid-line of the vagina. High up I could feel something like a loop of thickened bowel; I pulled this down and found it was a non-vascular thick-walled sac with a small hole at the side from which dark brown menses exuded. On cutting into this I found the cervix, which I was able to pull down. The sac was attached all around it about 1½ inches above the os; this I excised, leaving enough edge to sew it to the cut vagina. The tissues healed well and when the patient was discharged her vagina appeared normal. She menstruated a few weeks later without pain and has since become pregnant.

Women's Hospital, Isfahan, Persia.

Reports of Societies.

LEAD IN THE TREATMENT OF MALIGNANT DISEASE.

DEBATE AT THE MEDICAL SOCIETY OF LONDON.

At the Medical Society of London on March 22nd, with Sir HOLBURN WARING in the chair, Dr. W. BLAIR BELL, professor of obstetrics and gynaecology in the University of Liverpool, delivered an address on the use of lead in the treatment of malignant disease. The society's room was crowded to the doors, and many members stood during the whole three hours of the proceedings. The address was followed by an animated discussion, in which criticisms were expressed in a way unusual in a medical assembly.

Professor Blair Bell's Address.

Professor BLAIR BELL, after appealing for well informed criticism, first described what he called his working hypothesis, which he had been endeavouring to convert into a scientific generalization beyond dispute. He believed that there were many predisposing causes of malignant disease. Clinical experience strongly suggested as much. Many factors were concerned in producing a common condition in the cell—some condition of metabolic starvation—which was going to develop possibly into cancer. Attacked in this way, the cell might recover, or might die, or, as a third alternative, might revert to an ancestral type—the trophoblast, the earliest functioning cell of the human ovum—in its efforts to live. A cell which reverted in this way underwent a process which should be described as dedifferentiation. It had often been stated by pathologists that the more malignant a cancer the more undifferentiated were the cells; the proper word was "dedifferentiated." Such was the hypothesis, but before it could be turned into a generalization an actual resemblance must be proved between the cancer cell and the core of the cell of a chorionic epithelium. This resemblance was made evident along various lines of investigation. By the exhibition of sections he showed that morphologically there were similar features in the early developing trophoblast to those found both in cancer and sarcoma. With regard to chemical evidence, he added the phosphatide-cholesterol ratio, which ascended markedly as one went from normal tissue to innocent and to malignant neoplasms, and was highest of all in chorionic villi, suggesting that the chorionic villi were a supermalignant type of cell. The high phosphatide-cholesterol ratio was associated with permeability of the cell membrane, such permeability, of course, favouring rapid growth, and of all tissues chorionic villi were the most permeable. With regard to physiological evidence, until two years ago none of value could be produced to show that there was any real metabolic difference between the cancer and any other cell; recently Warburg of Berlin took up the study of the glycolytic power of various tissues, and showed that, whereas the ordinary resting type of cell obtained its energy by an oxidation process, the cancer cell did so by a glycolytic process, and Murphy and Hawkins in 1925 showed that in the chorionic villi the type of metabolism was similar in this respect to that of frank malignant tissue, thus again suggesting that the chorion was a supermalignant type of cell. He next touched on the toxicological features which bore out the same conclusion. The toxicological attributes of a cell were entirely dependent on its chemical and physico-chemical constitution, and here he showed sections of growths from patients who had died, illustrating the effect after treatment with doses of lead. The changes were such as again to prove the close similarity between the cancer cells and the cells of the chorion. Some of those present would have seen the criticism of the Medical Research Council on his statement and that workers poisoned by lead did not develop cancer, and his own rejoinder (*British Medical Journal*, March 6th, p. 432), which had not elicited any further response. He had made the statement guardedly, because there must be a case or two of cancer among so large a number of subjects, but cancer was of such rarity among sufferers from lead poisoning that Hoffman, the American statis-

tician, who was conducting investigations both into cancer and into chronic lead poisoning, stated that he had never seen a case of chronic lead poisoning in which a tumour formation, whether malignant or benign, was mentioned as a collateral or contributory cause of death. One would have expected better things from the Medical Research Council, with its strong statistical committee, than that it should take a group like potters, 80 per cent. of whom never went near lead at all.

With regard to treatment, Professor Bell said that a large body of the medical profession, as well as of the lay public, were searching the heavens for a cure for cancer. Such a panacea would never be found. The medical profession should guide the public on this matter to a different outlook. Very much depended upon early recognition of the disease. Cases had come to him practically in a dying condition, in which any form of treatment must fail. He protested against the unfairness of setting the results from lead treatment alongside surgical procedures, when the lead treatment had been applied at an advanced stage, and in cases in which surgical procedure and perhaps x rays and radium had been used ineffectually for a long period previously. He quoted some statistics from the United States to show that operation cured less than 5 per cent. of cases of cancer. He regarded his own results, not as conclusive with regard to the claims of a particular form of treatment, but as confirmatory evidence of the scientific work following upon the original hypothesis. It was fortunate, of course, that at a first attempt there should be so many remarkable results. It had been said that he had exaggerated the risks of lead treatment. But lead was an extremely dangerous drug; the workers along this line of research had had their disasters, and still had much to learn in the way of safeguarding the patient. He desired that the method should be tried out by people who had proper laboratory facilities and were capable of making sound scientific judgements. He and his colleagues were anxious, however, not so much to put forward a new form of treatment as to establish a sound generalization from which research could proceed upon other drugs and substances in the treatment of cancer. They had been so fortunate with lead that it was difficult for him to suggest to his staff or to visitors that anything else need be tried; but it was, nevertheless, necessary to find something which would do the work without producing the disasters, few though they were, relatively speaking, which had occurred with lead. The many successes were apt to be forgotten by those engaged in the work, but the failures were a constant nightmare. He showed pictures of a couple of recovered cases. One was a cancer of the breast treated five and a half years ago; the woman had recovered and had had two children since. The other was a case of sarcoma of the scapula, in which treatment had ceased two years ago, and the man now had no sign of the former condition and was quite well. Professor Bell produced in tabular form on the screen the results of his cases during the last five years:

	Cases.
Admitted, but died before treatment could be commenced ...	20
Died before treatment could be completed ...	50
Died of intercurrent affections ...	3
Died after treatment (including two deaths from acute nephritis, the result of lead poisoning) ...	106
Died as a result of extensive destruction of growth by lead ...	4
Too recent for results to be estimated ...	14
Complete treatment refused, but patients living normal lives ...	9
Disease completely arrested ...	10
Believed cured; treatment stopped ...	31
	227

Evidence of Liverpool Fellow Workers.

Dr. LESLIE CUNNINGHAM (Liverpool), who during the last few years has been associated with Professor Blair Bell in his work, said that before treatment was started in these cases a blood analysis was made, the haemoglobin and the blood urea were estimated, and in some cases the blood sugar, an exhaustive analysis was made of the urine, and in cases in which renal inadequacy was suspected other

tests of renal efficiency were performed. The hepatic efficiency was also determined in cases in which there was reason to suspect liver involvement. In the course of treatment these estimations were repeated from time to time. The toxic effects had been noted, not only on the blood and blood-forming organs, but on the kidney, liver, alimentary canal, and in a less degree on the nervous system. Several factors contributed to these toxic effects of lead, among the most important being the susceptibility of the individual. Some people would tolerate a large amount of lead; others, after a moderate dose, would be violently ill, and might even die. Younger patients tolerated lead less well than older, and females less well than males. Provided there was no cachexia, a patient with a large growth usually tolerated lead quite well. The toxic effects on the blood included stippling of the red corpuscles, the appearance of abnormal cells, and polychromasia. The stippling of the red cells had been of great value in the estimation of toxic effects. Its appearance was an indication that treatment should be stopped, at any rate for the time being. The anaemia produced had been so great in some cases that it was necessary to resort to transfusion, and it was remarkable how rapidly after transfusion the patients recovered. The alimentary manifestations were nausea and vomiting. Until the middle of 1924 small doses of lead were given over a protracted period, and occasionally cumulative effects which were very serious were found. With the larger doses now used—0.15 gram—the symptoms were produced rapidly, but they tended to disappear rapidly also, and provided the interval was long enough there was no permanent damage. Since the larger doses were employed lead colic had been found to occur. True lead colic and lead sickness did not appear until perhaps ten days after injection. Constipation and diarrhoea had not given much trouble. Often the earliest and not the least important toxic effect of lead was on the kidney, and it was here that the worst disasters had occurred. He showed charts illustrating the progress of two fatal cases—one following a moderate and the other a massive dose. Some of the symptoms were probably due to the involvement of the liver, which in cases of generalized poisoning was the first line of defence.

Dr. J. G. ADAMI (Liverpool) said that he had heard it stated, almost as a criticism of Professor Blair Bell, that the central problem of cancer was the discovery and establishment of its cause or causes, from which discovery one could proceed in a scientific manner towards prevention and cure. He believed that was a wrong point of view. As medical men their central problem was not cause, but arrest and cure. He was a greater benefactor to humanity and a greater man of science who kept before him always the higher goal, not obscuring it by any mere pursuit of science for science' sake. All great men of science had made their most fruitful discoveries, not for the purpose of adding to knowledge as such, but for the service of mankind. When Pasteur took up the study of rabies he could not find the cause, but he did not therefore withdraw from the subject or spend long years upon that particular quest; instead, he proceeded to establish immunity. To-day, nearly fifty years later, the cause of rabies was still in doubt, but the arrest or prevention of rabies had been placed on a sure basis. The various forms of new growth and of malignant disease had to be regarded as following a great number of predisposing or proximate causes, and there was a good deal of reason for supposing that this matter would not be determined by the discovery of, say, a specific organism. The duty of investigators was therefore rather to look to the arrest of the disease, and to study the cancer cell and the means of destroying it when once it appeared. It was most politic and wise to do as Professor Bell had done and to study the characteristics of the cells. He (Dr. Adami) had been following this work with the keenest interest, he had seen a great number of cases, and he could give the assurance that this work had been performed on the most scientific basis. Professor Bell, following upon his first fifty cases, had placed himself in the hands of an expert committee, and it might now be said that the work was not entirely Professor Bell's own, but was the co-ordinated work of a number of scientific men. A complicated subject like this, with so many

different sides to the problem it presented, was beyond the range of any single man; only by group working could advances be made.

General Discussion.

Sir LENTHAL CHEATLE said that he had known Professor Blair Bell throughout his career, and he had always found him a man of the highest integrity. He was sure that his actions were guided by the very purest motives. He agreed also that he was performing a useful pioneer work in trying to discover the effects of poisons upon tissue cells. But when Professor Bell likened the epithelium of the chorionic villi to malignant growth and based a great theory upon it, it seemed to the speaker that he was making an absolutely fundamental mistake. The chorionic villi were not malignant growths, and did not behave as such; so that any theory based upon such supposed resemblance struck him as profoundly misconceived. He could agree that when a little more was known about that which induced carcinoma, then the chemical and morphological similarities which Professor Bell had pointed out would be of some interest; but he believed, nevertheless, that such interest would be subsidiary. He thought also that Professor Bell was unduly pessimistic with regard to the supposed impossibility of a cure for cancer, and that the statistics he gave from America, showing that surgical operations yielded no more than 5 per cent. of cures, required very careful analysis. There were different types of carcinoma, and while, in respect to certain types, especially what the Americans called "outspoken carcinoma," operation was practically hopeless, in others, like carcinoma of the breast without enlargement of the glands, quite a large proportion of cures might be expected. There was a great deal in Professor Bell's work which he did not understand in the least, but he congratulated him upon a pioneer effort.

Mr. C. J. BOND (Leicester) said that he had had the pleasure of seeing some of the cases which Professor Blair Bell had described, and of examining them alongside the microscopical sections. The results were such as to produce a great effect on the mind of an unprejudiced surgeon. They were all familiar with certain cases of retrogression clinically in this dreadful disease; and it might be said that that was the explanation in these instances; but he did not think so—he believed there was something more. The cases described, particularly that of the woman who had a cancerous breast five years ago, and after treatment had not only lived but had suckled two children, could not be lightly dismissed. With regard to the physiological aspect of the problem, what Professor Bell had to show was the way in which the lead got to these cells—both cancer cells and normal cells—and what happened to the cell when the lead, either in colloidal or other form, was taken out. He (the speaker) had been studying the effect of feeding living leucocytes with lead in different forms. About half a dozen different forms of lead had been employed, including latterly the colloidal form, and he had satisfied himself as well as the colleagues to whom he had shown the specimens that the leucocytes did take up lead, especially, for instance, lead chlorido crystallized under special conditions and with special care, previously mixed with a little blood serum. The leucocytes, after the ingestion of these lead particles, went through a sharp metabolic downfall, and the question was whether the lead attached itself to the lecithin element in the cell. There was increasing evidence that it was to the lipid content of the normal cell that the lead attached itself, and thereby produced its result. What he looked to Professor Bell to show was the nature of the happening in the cancer cells in regard to lead content and the respect in which it was different from the happening in the normal cell. If the cancer cell had a higher lecithin content, then some sort of working hypothesis seemed likely to emerge.

Dr. ARCHIBALD LEITCH said that if Professor Blair Bell's work had met with hostile criticism, if his cures had been received with incredulity, and even his methods called into question, he had only himself to blame. The cardinal mistake was made when, in 1922, there was allowed to be published in the *Lancet* an article setting forth cures, and yet withholding from the medical profession all details as to what it was that was done. It was said then, and it

had been said since, that this work was on an experimental basis, and from that day to this the method had never been disclosed. There was an apologia published in the *British Medical Journal* recently (March 6th, p. 431) in reply to accusations made in various quarters that the method of preparation of the material had not been disclosed, and there it was stated that "So long ago as February, 1924, Professor Blair Bell described and discussed the method of preparation of colloidal lead." This could only refer to an article published in the *Lancet* in 1924, in which, however, the speaker was unable to find what it was now suggested had been given. He was very much surprised that Dr. Adami had allowed his name to be used in the "manifesto" published in the *British Medical Journal* of March 6th, for, the speaker asserted, the details of the method of preparation had never been given as they were stated in that manifesto to have been given. He challenged Professor Bell to read to the meeting the part of the article referred to which purported to give the secret away, and to let those present judge how far in fact the secret was given. He went on to give a summary of what had been set forth in the *Lancet* article, and claimed that it furnished no real information. In his latest paper, in the *Lancet* of March 13th, 1926, it was true that Professor Bell disclosed a little more information, but the speaker was still of opinion that even with these further details it was impossible for any physical chemist to state exactly what was being done. The apologia referred to also said: "The very fact that the general body of practitioners appears to be ready to use the material if it be distributed without control, to the possible disparagement of the method and serious risk to the public, has impelled the committee recently to protect the method of manufacture, as was done in the case of insulin." This meant that it had been patented. The patenting of insulin was certainly a mistake, but two blacks did not make a white. A search over the patent list would not disclose what this remedy was. If the applications for provisional patents were scanned it would be found that when temporary protection was given no specification was available for the public. A search through that list revealed that on October 26th, 1925, Messrs. Blair Bell, R. D. Cohen, J. A. Smith, and W. C. Lewis applied for a provisional patent for improvements in the manufacture of certain products (No. 26726). It was very certain that no patent would have been applied for, still less granted, for any well known method. The speaker then went on to criticize the accounts given of the cases. In the *Lancet* of March 13th Dr. Adami vouched for the fact that he had seen thirty previously incurable cases of cancer cured; he had also had letters from another ten cases. (At this point Dr. Adami protested that he had not described them as "cures," and Dr. Leitch amended his remark by saying, "Well, they had no recurrences.") But Professor Bell himself up to that time claimed only thirty-one. Looking over the cases that Professor Bell had recorded he (Dr. Leitch) could identify only three as having been reported more than once, and he proceeded to read the reports on these three cases, and to point out that in certain details the reports of the same case varied. In one of the patients who died, for instance, a case of carcinoma of the breast, one report stated that the growth had shrunk by one-half, and another report that it had shrunk by one-third. One case was described by Professor Bell in his address at Toronto. This case—a cure—was painted in rather high colours, and the account ended with the words, "She was married to-day." But the same case was reported a month later in the more sombre atmosphere of Glasgow, and the tones then were very much lower. There was even a difference in the lady's age. Not a word was said about the intestines being involved, or the whole abdomen, of which much was made in the first instance at Toronto. In a third case—again a patient who had recovered—there were different accounts as to the particular time at which the surgeons had declared the growth inoperable, and the time it took for the condition to heal varied also in each case. This was just sloppy reporting, but taking all these things into consideration he was rendered particularly sceptical of the whole matter.

Mr. C. A. JOLL thought that Professor Blair Bell had been far too apprehensive about the risks involved in giving the details of his methods to the medical profession. No doubt he was right in assuming that if this preparation were generally used by unskilled practitioners many disasters might follow. But the speaker was sure, not only that he would be perfectly safe to-day, but that he would have been perfectly safe two years ago, in giving every detail to properly organized institutions such as existed in London and in the large cities. The result of such a course would have been that judgement could be based, not on something over 200 cases as at present, but on 2,000 cases or perhaps 20,000. It should be borne in mind that over 100,000 people died from cancer in England and Wales in 1925. If Professor Bell had any doubt whether clinical material was available, it might be mentioned that at the Cancer Hospital alone over 2,000 new cases of cancer were treated last year. He would pass over all the questions on which Dr. Leitch had touched as to the preparation of the material, but he would urge Professor Bell for the sake of humanity, if this lead preparation was a legitimate and scientific cure for cancer, to give every possible facility to properly organized institutions to test its value and to present their reports.

Sir WILLIAM WILCOX said that the toxicological aspect of the question appealed most to him. He wished to join with Dr. Adami and Mr. Bond in expressing admiration for the very great care with which this work had been done, for the combination of experts who had taken part in it, and for their careful and critical analysis—a method of procedure which might well be copied in other researches. A remedy had been chosen by Professor Blair Bell which was one of the most powerful toxicological agents in existence. Lead was one of the most dangerous of poisons. It was a heavy metal, it fixed itself in combination with the tissues, and it was excreted extremely slowly. A little time ago he saw a case of high blood pressure and arteriosclerosis as to which there was some question whether the condition was caused by lead. The man had not been in contact with lead for a year, but it was found, nevertheless, that lead was being excreted in quite appreciable amounts. The speaker had had no experience of the toxic effects of lead when given intravenously, and he was unaware that it had been so given until within the last four or five years, but he did know that lead which was absorbed into the system was combined with the tissues of the body, with the kidney cells, the liver cells, the nervous tissues, that it was excreted very slowly—much more slowly than arsenic—and that it produced, certainly when absorbed by the mouth, irreparable damage. He thought, therefore, that this method of treatment from the toxicological side demanded the most critical examination, and he had certainly gained the impression from Professor Bell's address that he was quite familiar with the danger. Professor Bell realized that he was dealing with a very powerful toxicological remedy. It was interesting to hear that the method of giving repeated small doses had been withdrawn in favour of the massive dose. He took it that the reason for this was that when lead was given intravenously a certain amount (x) was fixed in the body, and a certain amount (y) excreted, and that the ratio x/y was greater with the small dose than with the large. In other words, the massive dose might put the patient in danger of his life, but a larger proportion of the lead was got rid of, and there was less permanent damage. He wished to ask Professor Bell whether he had observed, in any cases treated some years ago, a change in the blood pressure, in the blood vessels, or in the renal or hepatic function. The liver, as he had observed on a former occasion, was the first line of defence in the case of all poisons, especially those given intravenously. The acute symptoms, such as vomiting, which had been observed in these cases, were, he thought, not due to the action of the lead on the gastro-intestinal tract, but were probably due to auto-intoxication from temporary paralysis of the function of the liver cells. Professor Bell had said that in two cases there were symptoms of acute nephritis. Probably what happened was just the same as happened with mercury—not an acute nephritis proper, but a degeneration of the cells of the kidney, with

loss of function and paralysis of excretion. If there were acute nephritis there would be blood and casts in the urine, marked oedema, and so on. Lead was a powerful, double-edged weapon, potent for good or harm, and from the toxicological aspect it required the greatest care and prolonged investigation in order that doses might be given which, while acting on the cancer cells, would not produce harmful effects on the healthy tissues.

Mr. D. C. L. FITZWILLIAMS said that he did not think that anybody could have listened to Professor Blair Bell without being struck with his sincerity and his high ideals in scientific work. ("Hear, hear.") At the same time the speaker had to offer some criticisms which he hoped would be taken in the right spirit. There were certain things disquieting in this matter. He had heard some very cruel accusations made, and had passed them by. But he believed, with Mr. Joll, that Professor Bell had overrated the danger of making his method available to the profession. He (the speaker) had himself been treating cases with lead for some time, and had had no trouble whatsoever. By "back-door methods" he discovered a little while ago what was the method and the material which Professor Bell used, and with which, he believed, he produced his first cures—namely, the iodide A1 and A2—and this was a perfectly stable preparation. So little trouble had he found with it that during the last week he had given it to four practitioners to administer to people under his care. At the hospital, of course, one was able to have the blood tested and all the excretions looked into, and so forth, but if this method was to be of any value it must pass from the specialist to the general practitioner. Cancer was so common among the whole population that the specialists alone could not deal with it. He would have been much more reassured if Professor Bell had brought down a chorus of enthusiastic young surgeons who had been able to back up his results in the way they would all like them to be confirmed. Another disquieting factor was with regard to blood changes and so on; none of these things were published, and it was a great pity they were not published. Lister could never have established his antiseptic theory if he had kept it to himself. He established it by the energy and enthusiasm which he inspired in every worker, and every worker was welcome to his laboratory. That spirit had been singularly absent from the work of Professor Bell, and Mr. Fitzwilliams was of opinion that neither on the ground of the instability of the drug he had used, nor on the ground of its toxicity, was the secrecy justified. He (the speaker) wrote and asked Professor Bell if he could visit his laboratory, and the answer he received was that he could only come as the representative of some society. If the president of that meeting could extract from Professor Bell an invitation to those interested in the subject to see the cases and the methods, he would have presided over not only a most interesting but a most useful occasion.

Mr. F. A. G. JEANS (Liverpool) said that he was able to offer clinical confirmation of certain of Professor Blair Bell's results. Though not associated with the team in Liverpool, he had been interested in the work. As a Liverpool surgeon also he wanted to pay a tribute to the sincerity of Professor Bell, and he thought that Dr. Leitch should not have been allowed to deliver in that society the speech to which he gave utterance, at all events without the disarming preamble which other speakers who wanted to say something disagreeable had been careful to employ.

Mr. FRANK COKE, who thought that Professor Blair Bell must be congratulated upon the hypothesis from which his work originated, said that with a colleague (Dr. J. B. Cook) at the West Middlesex Hospital he had been using lead for the past two years, and the results were published not long ago in the *British Medical Journal* (March 6th, 1926, p. 415). Two years was a short time for any work of this character. It occupied many months to provide a colloidal suspension of lead which could be given intravenously, and which could stand by for a considerable time without having to be freshly made on each occasion. Many more months were occupied in raising the dose to the proper level. They had now got a colloid which appeared to be very stable

indeed, and which they were accustomed to use in doses of 20 c.cm. two or three times a week without the slightest sign of protein shock or other disturbance. Favourable results had appeared in some cases. Doses were now being tried in larger amounts. On the question at such sharp issue in that discussion, he was inclined to agree that Professor Bell was in the right at first in following the course he did in maintaining secrecy; but a long time had now elapsed, and if it was true that "what Lancashire thinks to-day, the rest of England will be thinking to-morrow," the moment had arrived when England should be given the material for thinking, and when many should take a part in this work, preferably on some team basis.

Mr. L. E. C. NORBURY confirmed what Mr. Coke had said with regard to the work at the West Middlesex Hospital, as did another colleague engaged with Mr. Coke in the work.

Professor Blair Bell's Reply.

Professor BLAIR BELL was received with acclamation on rising at 11.15 p.m. to reply. He took up the last remark of Dr. Adami, and said that he had endeavoured to use the word "we" as much as possible in all this work, because much of it was due to the physiologist, the pathologist, the biochemist, and others. He thought that Sir Lenthal Cheatele was not justified in his remarks about the chorion, and he repeated the argument which he had developed at length in his address. He then turned to Dr. Leitch, with whom he found it extremely difficult to deal satisfactorily in view of what he described as the deplorable ignorance under which some of Dr. Leitch's statements had been made. He would not have thought that a scientific man holding an important post could have been found with so little knowledge of chemistry or ordinary physical facts. To say that in February, 1924, no fair description of this method was published was absolutely untrue. He agreed that in the paper in question he did not bother to explain certain details, but these related to kindergarten science, and he assumed that the facts would be common knowledge to anyone interested; if not, there were plenty of textbooks in physical chemistry available. Anyone who could not have repeated his work from that paper ought to go out of science and hide his head. Dr. Leitch's speech was unpardonable. He (Professor Bell) had been engaged on this work at his own personal cost for all these years. When the Association of Surgeons visited Liverpool every laboratory was open and he gave a demonstration. Nobody was prevented from coming. Many of his British and American colleagues had seen the material prepared. Mr. Fitzwilliams had complained that his own request had been refused. The truth was that those engaged on this work found it impossible, owing to pressure on their time, to take individual men round. What he thought he suggested to Mr. Fitzwilliams was that he should come with some of his colleagues from a society, when arrangements would be made to receive them as a party. (Mr. FITZWILLIAMS dissented from this interpretation of the letter.) That, at all events, was the sort of reply he had sent to individual inquirers. He repudiated the charge of secrecy. He had never been guilty of secrecy in his professional life, and he had published a great deal of work. The things in question were open to anyone who came with proper credentials to Liverpool. It had been the anxiety of all concerned that the method should be known, but they were aware that they were dealing with a dangerous drug, and if it had been allowed to go out while they were still unsure of its effects much harm might have been done and the whole of the work discredited. As for any errors in the accounts of cases, these were possibly attributable to the fact that the cases came under different observers at different times, and certainly in one instance that two sections of the growth were taken at different times. Slips in details and dates might creep in when descriptions were furnished at different periods, by different workers, of cases the treatment and observation of which were spread over a series of years. He took full responsibility for any slight disharmony in the different accounts, but he did not think that the truth of the whole narrative was seriously qualified.

TREATMENT OF EXOPHTHALMIC GOITRE.

THIS discussion (of which the first part was reported in our issue of March 13th, p. 478) was resumed at the Royal Society of Medicine on March 9th, when the chair was occupied by Sir LENTHAL CHEATELE, President of the Section of Surgery.

General Management and Indications for Operation.

The opening papers on general treatment by Professor F. R. FRASER and Mr. T. P. DUNHILL are printed in full at pages 555 and 557.

Dr. R. W. A. SALMOND dealt with the treatment of these cases by x rays, admitting that it was subsidiary to medical and surgical treatment. The cases in which he got the best results from x rays were those of a moderate degree of severity. He did not think it possible to ascertain beforehand how a given case would respond. The most obvious effect of the rays was an improvement in the general condition, disappearance of the palpation and tremors, and slowing of the pulse rate. As a preliminary, local foci of infection should be searched for and treated. No routine dosage could be laid down for all cases; each case must be a law unto itself. There must be adequate filtration of the rays—not less than 3 mm. of aluminium. Too prolonged treatment would be likely to lead to atrophy of the gland. Radiation treatment could be combined with the medical.

The CHAIRMAN said he disliked operating on a case of exophthalmic goitre which had been subjected to x rays, as he thought that such applications rendered the operation more difficult, because of the adhesions to surrounding structures, and he was not a believer in the value of x rays as a treatment of exophthalmic goitre. In the eastern and central parts of America, which he visited last year, the function of the physician in these cases seemed to be mainly the preparation of the patient for the surgeon. Some people in this country spoke as if operation for exophthalmic goitre was completely unnecessary. Barker, a writer and worker in America, considered that by careful dieting and attention to focal sepsis cases proceeded to a cure, but that was not the speaker's own view.

Professor G. R. MURRAY said he was particularly glad to learn the results of the intensive study and careful treatment of cases of the disease in the medical unit of which Professor Fraser had charge. Further investigations of this nature were practically only possible in similar circumstances, though Dr. Maude had made a most valuable study of cases of the condition a few years ago in his practice at Westerham, publishing a series of most instructive papers. Professor Murray's experience of the disease had been gathered in hospital and in his own practice. He differed from Barker as to the duration of the disease; he did not find that cases recovered without treatment in two or three years. There was a great variation in the duration in cases which ultimately made a good recovery. He favoured the use of the term "thyroid intoxication," though there was still no proof that in these cases there was any abnormal toxin, or any abnormal ingredient in the thyroid secretion in the disease. His experience had been that the secondary form was much less common than the primary: in his own 300 cases, 288 were primary and only 12 of the secondary type. Sometimes a case of simple thyroid intoxication became, later, a well marked and fully developed case of Graves's disease. It was true that the cause was not known, but he was inclined to lay special stress on the emotional factor in considering possible causes; in his 300 cases shock and emotional anxiety figured in 18 per cent. He also agreed as to the importance of infections. Early diagnosis was very important, so that the patient might come under treatment as soon as possible. He asked that general practitioners should make a careful examination of patients presenting the symptoms associated with goitre, and that they should be less ready to label them neurasthenia. He did not doubt the value of x rays in treatment of the disease. It was necessary to lay down very exact rules as to the amount of rest these patients should take, and

not be satisfied with a general direction about resting as much as possible. It must never be forgotten that this was a disease of long duration, and much patience was needed in its treatment; many patients, for economic reasons, were unable to rest as required. He agreed that the diet must be liberal; there was a tendency to lose a great deal of weight. One patient put on 4 st. in weight on x-ray treatment. His own practice was to warn patients against taking much red meat, since Chalmers Watson had found that feeding experimental animals on a generous meat diet resulted in an enlargement of the thyroid gland. A good deal of milk should be taken. In his own experience the effects of iodine on the disease were only transitory, though admittedly it had special uses in preparing patients for operation; he was not much impressed with the routine use of iodine. A fall in the pulse rate he regarded as a valuable indication that treatment was doing good. X-ray treatment, valuable though it was, was apt to fail in certain cases, particularly when the goitre was larger than the average. Radium was dangerous in acute cases—it seemed to cause a crisis.

Dr. DOUGLAS WEBSTER said that usually the radiologist saw a more severe type of case than the ordinary practitioner. Of a series of 107 cases, 88 showed marked improvement after being subjected to x-ray treatment; four were acute, and all did well.

The concluding sitting in the discussion on the treatment of exophthalmic goitre was held on March 10th, the chair being taken by Dr. HUGH THURSFIELD, President of the Section of Medicine.

Dr. JENNER HOSKIN analysed 130 cases of the disease from the standpoint of the indications of disease revealed in electro-cardiograms. The ages of the patients ranged from 13 to 60, and only ten were males. Nine had a serious myocardial condition; 56 per cent. of patients who had a healthy myocardium were under 30 years of age. Study of the cases showed that it was unwise to wait long before operating in the cases which did not show an early response to medical treatment. It was in cases of secondary Graves's disease that the heart was found to be most damaged, especially when the disease had been active a long time. He agreed with Dr. McNee that the pulse rate was a very fair indication of the amount of thyroid activity. A systolic blood pressure of over 160 mm. showed that either rest in bed, primary ligation, or a modified enucleation was required.

Mr. LIONEL NORMERY spoke highly of primary ligation in some severe cases of goitre; he reported very good results in some cases.

Dr. W. LANGDON BROWN emphasized the emotional or psychic factor in the disease, believing this to be an important factor in determining exacerbations, if not actually playing a large part in causation. He was also much impressed with the importance of tonsillar sepsis in the disease. Insulin would often stabilize the patient's weight in exophthalmic goitre.

Dr. J. W. MCNEE called attention to a specimen of a foetus in University College museum. The mother had advanced Graves's disease, and the foetus had very prominent eyes, a very large thyroid gland, and other physical characters found in exophthalmic goitre. It suggested that the condition could be transferred from mother to offspring.

Dr. H. E. B. CALVERT said he used insulin in this disease as it seemed to take the strain off the thyroid gland and transfer it to the pancreas. Most cases of exophthalmic goitre had defective stomach secretion, and the administration of insulin seemed to remedy this defect; certainly after insulin the appetite was improved.

Professor F. R. FRASER, replying on the whole discussion, pleaded for a differentiation of the disease into types, for until that was agreed upon there could be no comparison of notes of different workers. He agreed that sex elements seemed to have a definite influence in determining the exacerbations in the disease. He hoped Dr. Hoskin and others would supplement the electro-cardiogram studies, and so be able to give definite indications of heart damage.

Mr. T. P. DUNNILL reiterated his chief guiding principles in dealing with cases of the disease, and expressed

his great satisfaction that physician and surgeon fully recognized the need for each other's help. He would never operate on a patient within three months of the onset of symptoms.

Dr. R. W. A. SALMOND also replied to the observations on x-ray treatment which Professor Murray made at the previous meeting. He agreed that patients with very large goitres did not do so well under x rays as those with smaller ones. Radium, however, could be applied to a very ill patient without removing her from bed.

ANTE-PARTUM HAEMORRHAGE.

At a meeting of the Section of Obstetrics and Gynaecology at the Royal Society of Medicine on March 4th, with Dr. EARDLEY HOLLAND, vice-president, in the chair, Dr. GIBBON FITZGIBBON read a paper entitled "A revised conception of ante-partum haemorrhage."

Dr. FitzGibbon reviewed the result of his observation of accidental haemorrhage during the last six years; he had been led to make this inquiry by noting that the accepted views of the pathology of the disease could not explain certain clinical facts. He found it impossible to accept the theory that the concealed type of haemorrhage was due to a disease of the muscle which rendered it paralytic. Toxaemia could not be held accountable for the majority of the cases. Absorption of the extravasated blood and its by-products could not explain the toxaemia. The supposed diseased condition of the uterine muscle was not consistent with the results of the various treatments. During the operation of Caesarean section the supposed paralytic uterus failed neither to contract nor to bleed. The mortality at the Rotunda Hospital from palliative treatment was 10.7 per cent. from plugging, 12.5 per cent. from Caesarean section, and from hysterectomy 66 per cent. From a study of cases Dr. FitzGibbon claimed that Caesarean section, hysterectomy, or other operative intervention was not good treatment for accidental haemorrhage, and, after consideration of the results of treatment, he had been led to abandon all operative treatment, including plugging. Under his medical treatment during the last six years the mortality had been 64 intern cases with 3 deaths, 34 extern cases with 4 deaths. While admitting that the disease was probably a result of toxaemia, he claimed that it was a different toxaemia from that of eclampsia. The two views of cases put forward were: (1) a simple and truly accidental ablation of part of the placenta, and (2) a toxaemic condition due to haematoma or apoplexy of the uterine wall involving the placental site in common with the rest of the uterine wall, but not originating in the placental site. The second group was very largely composed of multiparae, some 90 per cent., and all patients had albuminuria. Evidence seemed to point to the fact that repeated child-bearing and associated chronic nephritis were the causes. The symptoms of the second type were dependent upon the gradual accumulation of blood within the uterus and in the uterine wall. This haemorrhage was progressive over many days before any suggestion of the condition. After a certain amount of blood had been lost, the patient became collapsed. The essential fact to be observed was that the bleeding was never sudden or rapid—it had been going on slowly for many days. The collapse when present was not due to a sudden onset or increase of bleeding. The apparent increase in the size of the uterus was not due to the contained clot, but to its forward projection due to the increased tension of the muscle. The main lines of treatment were expectant. If the foetus was alive the patient was treated on purely palliative lines and watched. The occasional cases of persistent fresh bleeding might call for induction of labour after several days, but the others cleared up or ended in uneventful delivery. Patients showing toxaemic symptoms were treated by puncture of the membranes if the uterus was tense. The collapsed patient was disturbed as little as possible, and nothing more than puncture of the membranes was attempted, apart from very simple restorative measures. Plugging of the vagina was not advised, and Caesarean section was definitely condemned.

Dr. D. J. MALAN said he had looked up the records of thirty cases of accidental ante-partum haemorrhage, and the results of treatment in these made him unwilling to accept

the statement that the only treatment required was palliative and expectant; and that operative intervention was uncalled for and dangerous. How did Dr. FitzGibbon stop the bleeding when it continued in spite of palliative treatment? Dr. Malan had not found that in cases of concealed accidental haemorrhage the uterine muscle acted well. In three cases where Caesarean section was performed, two required subtotal hysterectomy, as the uterine muscle refused to contract properly. In the third case, the uterus was preserved only after prolonged efforts had been made to make it contract. Two of the three patients survived, and the last mentioned one gave birth six years later to a 9½-lb. baby after a normal pregnancy and labour. If chronic nephritis was the causal agent, then the haemorrhage should recur in subsequent pregnancies. This was not the speaker's experience, and he found it difficult to accept without further proof the explanation of Dr. FitzGibbon regarding the cause of accidental ante-partum haemorrhage.

Dr. R. H. PARAMORE referred to two cases of serious accidental haemorrhage under his care. In the one the membranes were ruptured, a great rush of blood occurred, and the patient immediately died. In the other, admitted as a case of placenta praevia with dead child, Caesarean section saved both mother and child. He was surprised that Dr. FitzGibbon denied that the uterine muscle was necrosed or degenerated in these cases in view of the work done by the late Gordon Ley. The speaker was under the impression that lesions of the uterine wall, and especially its haemorrhagic state, only occurred or were most marked in cases of concealed haemorrhage of magnitude. Absence of histological signs of cellular degeneration or necrosis was not evidence of functional activity. Dr. FitzGibbon had divided cases of accidental haemorrhage into two types: (1) simple, and (2) toxæmic. The toxæmia was due to chronic nephritis. But Dr. FitzGibbon apparently thought that the severe cases in which haemorrhagic extravasation into the uterine wall and broad ligaments occurred were always toxæmic and that the simple cases, such as those due to trauma, did not produce that state. The evidence was inconclusive. In the simple cases either there was no albuminuria or, if there was, Dr. FitzGibbon regarded it as a concomitant unassociated with the bleeding. The speaker believed the albuminuria in the traumatic cases was at times the result of the distension of the uterus by the bleeding. In order to understand how accidental haemorrhage occurred a study of the dynamics of the capillary circulation—and the placental sinuses were but modified capillaries—was necessary.

Mr. RIVETT agreed emphatically that there was more than one type of accidental haemorrhage, and that the so-called "toxæmic" type was a definite entity. He called attention to the fact that in many cases the amount of blood lost was not sufficient to account for the severity of the symptoms. He asked if the condition of the kidney in patients who died was in keeping with chronic nephritis, and also if those who had survived had subsequently showed clinical signs of this disease.

Dr. GIBSON FITZGIBBON, in reply, said that the kidneys in one of his fatal cases showed definite chronic nephritis; in his other fatal cases the kidneys were not examined. Of his patients who recovered several remained chronic invalids and were transferred to general hospitals, where one died nine months later. Subsequent pregnancies in the severe cases tended to terminate at earlier periods as abortions and miscarriages, and markedly resisted efforts to carry on the pregnancy. He had performed hysterectomy on two patients to stop this recurrent useless conception. In reply to Dr. Malan's question how the bleeding was to be stopped to allow recovery, the contention of Dr. FitzGibbon was that the bleeding was never rapid and did not require treatment.

Teaching and Practice of Midwifery.

Dr. G. W. THEOBALD, in a paper entitled "A plea for drastic reforms in the teaching and practice of midwifery," after drawing attention to the present mortality in childbirth, read a number of case-histories of obstetrical difficulties which had been mishandled before admission to hospital. He laid the blame for imperfect midwifery practice

in the country on the present system of teaching in the English maternity hospitals. After criticizing the general organization of the maternity hospitals, he suggested that obstetrical establishments should be staffed by senior resident officers. He also criticized the teaching of midwives and the conduct of normal labour.

Lady BAURET regarded the warnings against excessive intervention in the guarding of the perineum and the control of the uterus after birth as practically useful. Dr. Theobald had also indirectly suggested a way to avoid precipitate intervention in labour in private practice in consequence of the importunities of the patient and her friends; this was the more systematic use of suitable analgesics during the early stages of labour.

Dr. FAIRBANKS considered Dr. Theobald's paper timely and justified by the conditions now prevailing in the teaching and practice of midwifery. Reform was urgently required, and he would advocate a return to fundamental principles as the most essential need of the present day. Throughout medicine the ultimate objective was the maintenance of normal function, and in obstetrics efforts must be directed towards securing for patients a physiological pregnancy, parturition, and puerperium. Until this principle was recognized and acted upon whole-heartedly by all teaching and practising midwifery, the frequency of disasters would not be lessened. At the Portsmouth meeting of the British Medical Association he had urged a more extensive study of, and greater effort to attain, physiological parturition, but his views were regarded as visionary and impossible in practice. However well drilled students might be in the methods advocated by Dr. Theobald, few would be strong enough to overcome the pressure of patients and relatives to terminate labour early and artificially, and yet survive in the competition for practice. He knew striking instances of his own students and house-officers, strong both in faith and purpose, who had regretfully acknowledged defeat in the struggle. The public also required education, and without some change in the system and conditions of maternity practice reform, like the labours, would be difficult and delayed. A wider use of the services of the midwife must be part of the campaign on behalf of physiological parturition. If the true criterion of success was approximation to the physiological, the best results were to be found where the trained midwife conducted the labours and sent for medical aid only when there was need for it. This was shown not only by the better maternal mortality rates in those countries with a well organized service of midwives, but also by individual results in this country when this system was adopted. In working out the figures of the East End Mothers' Home for the past four years he had found over 95 per cent. of normal and unassisted deliveries, a forceps rate of about 1 per cent. in outdoor cases and under 4 per cent. in cases in the hospital, with only 6 maternal deaths in nearly 9,000 deliveries, or a rate of 0.65 per 1,000—about one-sixth of that of the country generally. The midwives of the Queen Victoria Jubilee Institute, who attended over 50,000 cases a year, had a rate of less than half the national rate, and in both these instances the medical assistance obtained by the midwife was that of a local practitioner. The Rotunda plan of having an experienced master resident for seven years in supreme charge in preference to visiting consultants had been advocated by the Committee on Teaching in a report to the council of the Section of Obstetrics and Gynaecology, and adopted by it in 1919—though there was a minority report against it.

Carcinoma Adenomatodes Cervicis Uteri.

Dr. HERBERT SPENCER described a case of carcinoma adenomatodes (adenoma malignum) cervicis uteri in a patient aged 49. Vaginal hysterectomy was performed with the Paquelin cautery, and the patient remained well after twenty-two years. Attention was drawn to the rarity of the disease, and the point was emphasized that in true cases of the disease the glandular epithelium was nowhere proliferated, and therefore that reliance on microscopic examination alone for the diagnosis might lead to serious error.

Dr. F. J. McCANN said that at the old Obstetrical Society in 1898 he had shown a specimen of what he termed malignant adenoma of the cervix uteri. The patient was aged 46, the mother of three children. Her uterus was enlarged to $1\frac{1}{2}$ inches above the symphysis pubis and distended with mucoid material, slightly blood-tinged. The cervix was nodular and excavated, forming a crateriform ulcer at the apex of the vagina, the cancerous growth spreading to the bladder anteriorly. Vaginal hysterectomy was performed in June, 1897, but the disease recurred locally, and secondary deposits invaded the liver, causing her death on December 9th, 1897. Sections made from the growth showed that it was composed of tubules lined by a single layer of columnar epithelium, the interstitial tissue being of a fibrocellular character and varying in amount. At the meeting at which the specimen was shown the opinion was expressed that this form of cancer was probably not very malignant, but in this instance at any rate recurrence was rapid.

Method of Endoscopic Examination of the Uterus, with its Indications.

Mr. H. F. SEXTON gave a description of the instrument he has devised for the examination of the interior of the uterine cavity; he claimed that by its use the whole of the endometrium could be carefully investigated by turning the instrument about. Important points in the technique were:

1. The cervix must be dilated up to the 9/12 dilator in order to take the full-sized tube of the instrument.
2. The examination must be made under general anaesthesia.
3. It was a direct focus observation; one could obtain a magnified image with the lens at the ocular end of the tube.
4. Suction was necessary at the beginning of the removal of blood, but this could be shut off towards the end; a little swabbing was necessary.
5. It was easy to remove a piece of the tissue by sight for the pathologist.

The indications for the use of the hysteroscope were:

1. Where diagnostic curettage was indicated, a hysteroscopic examination was likely to help.
2. Where there was uterine haemorrhage, either menorrhagia or metrorrhagia, and nothing abnormal could be felt on bimanual examination, the diagnosis could be cleared up by means of the hysteroscope.
3. Haemorrhage from the uterus after the menopause or a purulent discharge; here a carcinoma of the body could be seen, a snapping of the growth taken, and a diagnosis made between a degenerating fibroid and a carcinoma.
4. In certain cases some might be in doubt as to whether to treat a case of haemorrhage by hysterectomy, x rays, or radium. Here the scrutiny of the endometrium would help in coming to a decision.

Pregnancy complicated by Ureteric Calculus.

Mr. C. LANE ROBERTS described a case of pregnancy in which, after an attack of pyelitis, the urine became suppressed entirely at the eighth month.

An x-ray examination of the kidney and ureter showed nothing abnormal, and for four days not more than an ounce of urine was withdrawn from the bladder. Caesarean section was performed, when the right kidney was found to be enlarged to one and a half times its normal size, with much dilatation of pelvis and ureter; the left kidney was also enlarged. The right ureter palpated below the dilatation showed nothing abnormal; six hours after Caesarean section the right ureter was explored by ureteric catheter, when an obstruction was felt. Still, however, no urine was passed for ten days. A right pyelotomy was performed and much urine was drawn away from the hydronephrosis. On the second day after the operation the patient's general condition was fair, the blood urea having risen from 96 to 117 milligrams, but no urine was passed from the bladder, while the kidney wound was draining well. By the seventh day after the operation the patient passed urine normally. Three months after the Caesarean section the patient was operated on for perinephric abscess, and this was followed by removal of the ureteric calculus by the extraperitoneal route.

The interesting features of this case were: the length of time during which no urine was passed; the duration of the reflex anuria of the apparently healthy though hypertrophied left kidney, even after the removal of the obstruction; and the failure of x rays to help with the diagnosis of the obstruction; an almost complete absence of symptoms; and, finally, the mobility of the obstruction when it was discovered.

CLINICAL RELATIONS BETWEEN PSYCHOLOGICAL DISORDERS.

Dr. R. H. COLE presided at a meeting of the Psychiatric Section of the Royal Society of Medicine on March 8th, when Dr. THOMAS BEATON read a paper on the clinical relations between psychological disorders.

Dr. Beaton pointed out how patients suffering from the toxic or organic psychoses, such as general paralysis, tended to show the clinical syndromes of the biogenic type, and also the mixed schizophrenic and manic-depressive reactions which were often seen in the biogenic psychoses. In regard to the relation of the psychoneuroses and the psychoses, he doubted whether it was right to make a fundamental distinction between the two groups. For example, the different degrees of severity which could occur in anxiety symptoms varied from a mild anxiety neurosis up to a state of agitated melancholia in which control was lost and the patient might be in a state of hallucination and delusion. Again, the anxiety syndrome might complicate the clinical picture in psychoses such as paraphrenia. Dr. Beaton said that the obsessional state was commonly tinged with anxiety, and that a persistent psychasthenia might develop in two directions—either towards a resistive melancholia or a chronic hallucinatory psychosis. Reference was made to the way in which the hysterical reaction complicated many diseases.

In the discussion Dr. T. A. ROSS opposed the view that the clinical appearances of psychoneuroses and psychoses occurred at different times in the same illness, while other speakers cited examples in favour of Dr. Beaton's views. The PRESIDENT, in summing up, quoted a case of an obsessional neurosis which required certification owing to symptoms producing pronounced disorder of conduct.

PYELOGRAPHY IN DIAGNOSIS.

A MEETING of the Brighton and Sussex Medico-Chirurgical Society was held on March 4th, Mr. H. J. WALKER, the President, in the chair, when Mr. F. E. FEILDEN read a paper entitled "Some observations on pyelography and its value in diagnosis."

Mr. Feilden said that pyelography consisted of the introduction into the renal pelvis of a solution which was opaque to the x rays, and subsequently taking a radiogram. The interpretation of the picture required care and experience. It might not always be possible to diagnose the pathological condition, but with experience one could say with confidence that a given pyelogram represented a normal or a pathological condition. Frequently, pyelography was the only means of arriving at a correct diagnosis; especially was this so in some cases of painless haematuria. Pyelography suggested the probability that many cases of so-called essential haematuria were in reality cases of congenital hydronephrosis associated with haematuria. Pyelography was of value in obviating the necessity of waiting until the patient was bleeding in order to discover from which kidney the haemorrhage was coming. Pyelography was particularly useful in the diagnosis of hydronephrosis before there had been much destruction of renal tissue and before the onset of infection. In nephroptosis, pyelography demonstrated the presence or absence of associated kinking of the ureter. The absence of kinking of the ureter in these cases raised a doubt as to the advisability of operative intervention. Lateral x rays, pyelograms, and, in difficult cases, lateral pyelograms, were of assistance in distinguishing between a shadow in the kidney, in the region of the kidney, or in the gall bladder. Should a uric acid calculus be suspected in the kidney the patient should be examined radiologically after the solution had been removed from the renal pelvis; the staining of the stone would then accentuate the shadow. Normally, the right pelvis was slightly lower than the left; if the left pelvis was lower than the right there was some pathological reason for it. If either lay below the third lumbar vertebra it was abnormal. In cases where a pyelogram could not be taken owing to obstruction to the entrance of the solution, the resulting ureterogram might be of value; thus, a dilated ureter from ureteritis suggested an infection of the kidney, and a small ureter from disuse suggested a neoplasm.

In suspected renal tuberculosis, unassociated with gross changes in urine, pyelography, by revealing a pathological condition of the kidney, would indicate the appropriate line of treatment. In malignant disease of the kidney, pyelography showed a recognizable change in the renal pelvis in a large proportion of cases. An early tumour of the renal capsule would not be revealed by pyelography; in this case a radiogram, after perirenal infiltration with oxygen, would be of value as an aid to diagnosis. The importance of the symptoms "pain in the back" and "frequency" must not be underestimated, for either might be the patient's only complaint, yet his kidney might be the seat of gross pathological change. In cases of abdominal pain of obscure origin a pyelogram might be of the greatest assistance in obtaining a correct diagnosis. Pyelography was a safe and valuable procedure when performed with due regard to modern technique.

The PRESIDENT asked about the disastrous results recorded in the early days of pyelography, and Mr. FEILDEN said that the bad results were due to inexperience and the use of silver salts, which were very irritating in the pelvis, and calyces, resulting in focal necrosis.

Mr. J. R. H. TUNTON asked if a double pyelogram, without waiting for a period of three weeks, was a safe procedure. He also stressed the importance of not mistaking a calyx that had been cut across for a calculus. He considered pyelography should be used more frequently. Mr. FEILDEN said that to perform a bilateral pyelogram was a perfectly safe procedure; especially was it helpful in distinguishing between an early hydronephrosis and a normal but large renal pelvis. With experience one would not mistake a calyx (cut transversely) for a calculus.

Mr. J. GRIFFITH referred to a case of haematuria the diagnosis of which could not be established until Mr. Feilden prepared a pyelogram which definitely showed a stricture at the junction of the pelvis and ureter. This was treated by open operation, with satisfactory results. Dr. G. B. S. D. GRAY asked the cause of the pain that patients sometimes complained of after pyelography. Mr. FEILDEN said that it was very unusual for patients to complain of any pain or even discomfort after pyelography; usually it depended upon the operator's experience and technique. If the fluid was not removed from the pelvis spasm might be set up in the ureter. If there had been undue damage to the mucous membrane of the ureter the patient might have ureteric colic caused by blood clot.

Mr. M. FITZMAURICE-KELLY referred to the advantage of pyelography in cases of renal calculi so as to establish the exact position of the calculus. He also inquired what solution was used. Mr. FEILDEN said he always used 15 per cent. sodium iodide, as it gave an excellent shadow, and was not irritating to any part of the urinary tract. He drew attention to the danger of pyelography in a case where the calculus was lodged in the pelvis at the junction of the ureter. One should make sure that it was possible to remove the solution from the pelvis. Sometimes in these cases the calculus acted as a ball valve: the solution could be introduced but not removed.

CHRONIC INTUSSUSCEPTION.

At a joint meeting of the Manchester Medical Society and the Liverpool Medical Institution on March 3rd, Professor A. H. BURGESS, the President of the Manchester Medical Society, in the chair, Mr. R. C. DUN (Liverpool) read a paper on chronic intussusception, based on his experience of thirteen cases.

Mr. Dun drew comparisons between this variety of invagination of the bowel and the acute type. Chronic intussusception occurred much less frequently and in older children; the sexes were equally affected, and there was a larger proportion of the enteric and colic forms. The symptoms were slight, indefinite, intermittent, and prolonged; in the cases under review they had been present for four weeks up to two and a half years. The umbilical pain was usually slight and of a colicky nature, vomiting was occasional and concurrent with the attacks of pain, constipation was not marked, and there was always a deterioration in health. An abdominal tumour could be felt in nine out of the thirteen cases; it was intermittently

present, appearing and disappearing with the pain. In two cases only was it long enough to be called "sausage-shaped." Blood and mucus was present in only two of the cases, and in both appeared intermittently. Diagnosis was difficult owing to the evanescent nature of the abdominal tumour, and the importance of repeated examinations was stressed; examinations should be made during the attacks of pain. In no case had the intussusception progressed so far as to cause acute intestinal obstruction. The differential diagnosis between tuberculous peritonitis and chronic appendicitis was discussed. The treatment had been in all cases laparotomy and reduction; this had always been found easy, no adhesions had ever been found, and practically no oedema had been noted. In no case did the symptoms recur after operation. No obvious pathological condition had been met with in any of the cases which could account for the intussusception.

Cysts of the Semilunar Cartilage.

Mr. T. P. McMURRAY (Liverpool) made a report of eight cases of cysts of the semilunar cartilage, and said that, unlike the previously reported cases, three of the eight were in connexion with the internal semilunar cartilage, whereas the previously reported eighteen cases had all been associated with the external cartilage. The cysts were multilocular, containing clear fluid and requiring excision for the cure of the symptoms. Two of the eight cases had been already operated on by other surgeons, and the cysts alone were removed, with no relief of the symptoms. The eight cases were treated by complete removal of the cysts with the affected cartilage, and a complete cure resulted. Microscopical examination of the cyst wall showed that it was lined with compressed cartilage cells and intercellular strands with darkly staining nuclei, but no trace of endothelium or epithelium was found. Blood vessels occurred on the outside of the cysts, but not to the same extent as between the cysts. From the presence and from the position of the blood vessels connected with the cysts, it was concluded that the cysts were traumatic in origin, and entirely of the nature of degenerative change.

The Purgative Action of Magnesium Salts.

Dr. HENRY COHEN (Liverpool) read a paper on the purgative action of magnesium salts. In a brief historical sketch he pointed out that there were two main theories concerning the mode of action of the saline purgatives. The first was that their action was entirely local, being exerted solely from the lumen of the intestine; the second was that the saline purgatives acted, not from the lumen of the gut, but only after absorption of the cathartic ion. The evidence adduced in favour of both theories had been too conflicting so far to justify definite conclusions. Using a special micromethod for the estimation of magnesium in small quantities of serum, Dr. Cohen found that the oral administration of purgative doses of magnesium sulphate (20 to 30 grams) was unaccompanied by any definite alteration in the magnesium content of the serum. On the other hand, the intramuscular injection of magnesium sulphate in solution (18 to 20 c.cm. of a 10 per cent. aqueous solution) was followed by a considerable increase (50 to 100 per cent.) in the magnesium content of the serum, but in no case was this rise accompanied by the characteristic purgative effect of the salt when given by the mouth. Following a purgative dose of magnesium chloride a rise in the magnesium content of the serum did occur. This rise was, however, no higher and no less rapid than that following the intramuscular injection of magnesium sulphate. Since the latter did not cause purgation, it followed that the purgative action of magnesium salts was exerted independently of the absorption of magnesium into the blood. Dr. Cohen showed radiographs illustrating that, in the same individual, a purgative dose of magnesium sulphate increased the rate of passage of the opaque meal along the intestine, and also the bulk of the intestinal contents. Moreover, if the lower bowel was empty before the experiment, the first stool passed after administration of the purgative salt contained bismuth. Dr. Cohen concluded from the two sets of data he had presented that the purgative action of magnesium salts was entirely local, and independent of the absorption of magnesium into the blood stream.

PATENT INTERVENTRICULAR SEPTUM.

A CLINICAL meeting of the Aberdeen Medico-Chirurgical Society was held on February 4th, the President, Dr. J. CHROMBIE, in the chair. In the absence of Professor T. SHENNAN, Dr. W. BROWN read his description of a case of congenital heart disease, and illustrated the points by lantern slides from *post-mortem* photographs of the heart.

The patient was a male child, aged 12 weeks, who was never cyanosed but usually very dusky. There was great bulging of the precordia. On percussion and screening by *x* rays the heart was enlarged, especially towards the right. A slight thrill with systolic and diastolic murmurs was noted. A patent interventricular septum was suggested as a diagnosis. The patient died suddenly from respiratory catarrh. On examination of the heart *post mortem*, the interventricular septum was found to be patent in its lower muscular part only. In addition, there were several polypoid excrescences of a myxomatous nature on the mitral valve.

Dr. W. Brown also described four cases which had come under his care at the Royal Hospital for Sick Children; the chief points were illustrated by lantern slides. The first two cases were of hypertrophic pyloric stenosis, and Dr. Brown described two reliable tests for the dehydration of the tissues in this condition. The first was the loss of tension of the eyeball, and the second was that, on pinching up the skin of the abdomen, the elasticity of the skin having been lost, the pinched area took a long time to flatten out. It was necessary to remedy this dehydration before operative treatment, and this was accomplished by rectal feeding. Visible peristalsis of the stomach became more noticeable as the dehydration diminished. On observing the peristalsis it was noted that as a preliminary to the appearance of a wave the child cried, and there was a transverse wrinkling of the skin of the abdomen. The direction of the wave was from the left costal margin towards the umbilicus, and when the first wave had almost reached this point a second began and followed the first. A deep hollow was noted in front of the wave as it approached the umbilicus. Pain was not a usual feature of these cases. In both cases the usual symptom of constipation was absent. Radiography with a barium meal was not found to be of much assistance in diagnosis. The next case was one of pyloric spasm in a female child aged 2 months. Numerous contrasting points were demonstrated between this condition and that of hypertrophic pyloric stenosis. This child was usually sucking a finger—a point of some importance, as some authorities ascribed the cause of pyloric spasm to aerophagy. The Wassermann reaction was strongly positive. Some sixty hours after admission the first definite peristalsis was seen as a lump rising high up in the epigastrium, much higher than in pyloric stenosis. The tone of the stomach was good, and there was no dilatation compared with the atonic dilated stomach of stenosis. This case at first suggested one of pyloric stenosis owing to the extreme constipation, projectile vomiting, visible peristalsis, and rapid wasting. Several important points about pyloric spasm were illustrated by this patient—namely, the later age of onset, the prevalence in females, the peristalsis occurring high in the epigastrium, the absence of gastric dilatation, and the association with syphilis. The fourth patient was a boy, aged 2 years 8 months, with vomiting and pain in the abdomen. These vomiting attacks had no relation to the taking of food, and occurred on the eighth, eleventh, twelfth, fifteenth, sixteenth, twentieth, twenty-seventh, and thirty-seventh days after admission. Preceding and sometimes accompanying the vomiting were pain in the abdomen, visible peristalsis, and audible rumbling and gurgling. The Wassermann reaction was negative, but there was an intense reaction to human tuberculin. The peristaltic waves were very long from end to end, and the crest not very high. They were always constant in direction—namely, from the left costal margin downwards, diving under the umbilicus and reappearing below and to the right. After one or two sets of waves of this nature a formation of ball-like knobs appeared round the umbilicus, and their disappearance coincided with the rumbling noise and the passage of flatus. Six hours after a barium meal the report stated that a large and distended loop of small bowel was seen round the umbilicus. At an operation a loop of small bowel was found to be bound down by dense tuberculous adhesions.

An anastomosis was performed, and the child made an excellent recovery.

Dr. JOHN CRAIG described two cases, the first being one of amyotonia congenita in a male child aged 4 weeks. It was sent to hospital with a diagnosis of Erb's palsy of the left arm. When first seen in hospital both arms were held in the typical position of Erb's paralysis, but every now and then the child moved its arms in most directions. All the muscles of the trunk, arms, and legs were soft, small, and toneless, so that the child could be made to assume various fantastic attitudes. On testing the electrical reactions of the muscles, the faradic response was greatly diminished, but not lost; this feature was mentioned as being diagnostic. There was absence of the deep reflexes. The second case was one of pseudo-hypertrophic paralysis, exhibiting all the typical features. Both cases were illustrated by lantern slides.

At a recent meeting of the Royal Medico-Chirurgical Society of Glasgow, the President, Professor ARCHIBALD YOUNG, in the chair, a debate was held on exophthalmic goitre. Professor F. R. FRASER and Mr. T. P. DUNHILL opened the discussion on the same lines as those of their papers at the joint meeting of the Royal Society of Medicine on March 9th, which are printed in full at pages 555 and 557. Charts were shown to indicate the striking drop in the basal metabolic rate and pulse rate, and the rise in body weight following iodine treatment, and lantern slides illustrated the improvement in the eyes of patients treated surgically. In the discussion which followed Professor W. K. HUNTER, Dr. G. HERBERT CLARK, Dr. MARION GILCHRIST, Dr. J. MCKENZIE ANDERSON, Mr. J. SCOUER BUCHANAN, and the PRESIDENT took part.

At a meeting of the Nottingham Medico-Chirurgical Society on March 11th, Mr. H. BELL TAWSE, President, in the chair, Mr. W. E. HEMPSON, solicitor to the British Medical Association, delivered an address on the subject of "Medical men and the law." In the course of this address he pointed out that the laws governing different sections of the public and various classes of the community were as essential for the purpose of self-government on lines of orthodox propriety as statute law was for the regulation of the affairs of State. He then proceeded to deal with the subject of his address from the two aspects of ethical procedure and conduct, and the legal responsibilities associated with the practice of medicine and surgery, thereby covering a wide field in point of illustration and useful advice, based upon his large and varied experience. An interesting discussion followed, in which a variety of conundrums were propounded for Mr. Hempson's solution, and an evening of "free law" was much enjoyed and appreciated. The address was discussed by the PRESIDENT and Drs. THOMPSON, ISARD, HUNTER, ROWE, WEBBER, and HAMILTON.

A MEETING of the Chelsea Clinical Society was held at St. George's Hospital on February 16th, when a discussion on the endocrines was opened by Professor SWALE VINCENT. He said that the only instances of true substitution therapy at present available were those of the thyroid, the pancreas, and perhaps the ovary. Of these extracts only one, the thyroid, was known certainly to produce any effects when given by the mouth. Adrenin and the extract of the posterior lobe of the pituitary body were valuable as drugs apart altogether from any question of substitution therapy, and neither of these drugs had any effect when given orally. Dr. ERIC BELLINGHAM SMITH gave an account of the clinical manifestations of the diseases produced when the ductless glands were at fault. Dr. F. J. MCCANN laid stress on the value of thyroid extract and calcium lactate in disorders of menstruation in the young. These drugs were especially valuable in obese and anaemic subjects. Dr. H. A. ELLIS reported good results with small doses of adrenin in the type of fatigue occurring about middle age, but was certain that only quite small doses of the drug should be administered. A meeting was also held at the Florence Restaurant after dinner on March 16th, when a discussion was held on spa treatment. Drs. VIOLE, DEBIDOUR, and FERREYROLLE came from France to speak, and Drs. EDGECOMBE, CAMPBELL, RAY, and LIEVEN also took part in the discussion.

Reviews.

BIOCHEMISTRY.

Hexosamines and Mucoproteins,¹ by Dr. P. A. LEVENE, is the latest addition to the Monographs on Biochemistry so judiciously edited by Professor R. H. A. PLIMMER and Professor Sir F. G. HOPKINS. These "little grey books" occupy a distinguished and accessible place on any book-shelf consecrated to things biochemical. The series is of almost unbroken excellence, and this new recruit has every right to feel at home in its ranks. The discussion deals in succession with the structure of the hexosamines in relation to recent knowledge of the structure of the sugars, with the prosthetic group—chondroitin sulphuric acid—and with the structure of the whole mucoprotein molecule. Each section carries an appendix, invaluable in the laboratory, wherein are detailed the analytical and synthetic methods which have contributed data to the various arguments in the text.

Should this monograph fail to find so large a body of readers amongst students of biology as have many of its grey brethren, the reason must be sought in the nature and in the history of the author's subject. The hexosamines and mucoproteins appear to play largely an architectonic and protective function in the animal. The biologist is always ready—nay, impatient—to hear all that the organic chemist may have to tell him of the structure and behaviour of all substances whose significance to physiology, and in particular to metabolism, is apparent. He will submit to a heavy discipline in the conventions of organic structure in an attempt to comprehend more fully the biochemistry of these substances. When, however, he is presented with a chemistry, equally difficult, of materials which appear to have small relation to the dominant processes of vitality, who shall blame him if he be less diligent in their study? Of the 160 pages of the monograph under review, three suffice to tell all that we know, and much that we may surmise, of the why and wherefore of the presence of these substances in the skeleton, connective tissue, and mucus.

The author (and who else could approach the subject with the authority of Dr. Levene?) moves easily in a bewilderment of structural relationships, unfolding an ordered argument such as organic chemistry has learnt to develop with such facility. There is much in the story to intrigue the chemist, and when the full significance is established of the relations of the hexosamines to the simple sugars and of the mucoproteins to the simple proteins there will be much to attract the attention of the biologist.

Dr. OTTO FÜRTH's book on problems of physiological and pathological chemistry was first published in 1911. It immediately became one of the most popular books in its field and a considerable part of it appeared in the English language under the title of *Problems of Metabolism*. Many who made close friends with this translation may have been unaware that it represented only the second half of the whole work. The first half dealt with the chemistry of the constituents of living material. The book has become—or we should say that, after the fashion of Continental publishers, it is in process of becoming—a textbook. Professor Fürth is undertaking an extensive revision and elaboration of the whole. As before, the chemistry of the tissues and the chemistry of metabolism will form the main divisions of the subject, and the former will be published in three separate sections, of which the first is before us.² If the first section may be taken as a measure of the comprehensive character of the whole work, we hold the promise of an unusually valuable addition to the library of medical science. This part deals with the proteins, carbohydrates, fats, and the chemistry of blood. Its interests

are frankly in the classical vein, a legacy from the synthetic triumphs of organic chemistry. The student may occasionally be disappointed when he seeks in its pages a nice balance of the organic and the physical aspects of biochemistry, but within the limitations of its traditional view the work is excellent. Professor Fürth not only knows the literature, but, a more precious attribute, he understands the uses of the literature. Indeed, he enjoys leaving us with more problems than he sets out to solve. A second part is promised which will deal with the chemistry of muscle, nerve, and body fluids other than blood, and a third is to be devoted to the endocrine organs. A book so comprehensive will have few competitors. It may be too much to hope, but it is certainly desirable that this book should soon be made available in our own tongue to a larger body of readers than will, at present, be tempted to make frequent use of it. It well merits translation.

THORACIC SURGERY.

THE reader of Mr. HOWARD LILIENTHAL's *Thoracic Surgery* will not fail to be struck with the rapid advances that have been made of recent years in operative technique. It is probably fair to say that these would not have been possible except for the help that has been forthcoming from the physiologist and the radiologist. The latter especially has rendered assistance, not only in the diagnosis, but in the clinical progress of the patient. By his aid it is now possible to follow the gradual collapse of a lung, the obliteration of a cavity, alterations in the mediastinum, and numerous other changes that are difficult to recognize by clinical methods alone.

The two volumes presented to us survey the whole field of thoracic surgery. Primarily compiled from the personal experiences of the author, they are supplemented by articles on special subjects, such as physiology and the intravascular treatment of aneurysm, by others whose knowledge on these topics is more extensive than his own. The book, however, remains a record of personal work, more in the nature of a monograph than of a textbook. It is strange for a surgeon to learn the details of his handiwork from a physician, and still stranger for him to admit it; yet the author has not hesitated to include a long section on the artificial pneumothorax treatment of tuberculosis by two of the assistants at the Loomis Sanatorium. In this his wisdom is commendable; for though the surgeon will probably never be responsible for this method of treatment, it is as well that he should know it. In another matter too he may be congratulated. Though military surgery is of great importance during war, it plays but a small part in time of peace. He has therefore restricted the portion of the book dealing with this subject to a single chapter at the end.

As we have come to expect of the American publishers, the book is well and profusely illustrated. Some of the figures are perhaps unnecessary, but it is better to err on the side of clarity. It will be found of value chiefly to the specialist in thoracic surgery, but the chapters dealing with the surgical treatment of tuberculosis, of the pleura, and of the heart, will doubtless be welcomed by the physician too.

STATISTICAL METHODS FOR RESEARCH WORKERS.

MR. R. A. FISHER, the author of *Statistical Methods for Research Workers*,⁴ is known to the learned world as an able and original mathematical statistician, while, as chief statistician to the Rothamsted Experimental Station, he has had considerable experience of the application of quantitative methods to a particular class of biological problems. The aim of his present volume is to supply a manual for biological research workers desiring to evaluate statistically their experiments. Since, in the kind of biological research with which Mr. Fisher has had to deal

¹ *Hexosamines and Mucoproteins*. By P. A. Levene. Monographs on Biochemistry. Edited by R. H. A. Plimmer and Sir F. G. Hopkins. London and New York: Longmans, Green and Co. 1925. (Roy. 8vo, pp. x + 163, 10s. 6d. net.)

² *Lehrbuch der Physiologie*. Zugleich II. Teil der *Probleme der Physiologie*. Von O. Fürth. Organchemie; I. Lekt. Leipzig: F. O. W. Vogel. 1925. (Sup. roy. 8vo, pp. xiii + 208. M.15.)

³ *Thoracic Surgery*. In two volumes. By Howard Lilienthal, M.D., F.A.C.S. Philadelphia and London: W. B. Saunders Company. 1925. (Roy. 8vo: Vol. I, pp. viii + 694, 497 figures; Vol. II, pp. iv + 693, 406 figures. 80s. a set of two volumes.)

⁴ *Statistical Methods for Research Workers*. By R. A. Fisher, M.A. Biological Monographs and Manuals. Edinburgh and London: Oliver and Boyd. 1925. (Demy 8vo, pp. ix + 239; 10 figures. 15s. net.)

practically, small samples only are usually available, he has given considerably more attention to the particular methods applicable to small samples than authors of most textbooks have deemed necessary; he is well qualified to do so because of his previous mathematical investigations in that difficult branch of statistical theory. The chief merit, indeed, of his volume is that it provides numerous worked examples and tabular aids to calculation, which should be of service to those having to rely on small samples.

Mr. Fisher has designed his book for readers without special mathematical training, and is conscious that the inclusion of a good deal of matter which is "advanced," and has, indeed, not been published before, needs some explanation. If he feared that he was likely to fall between two stools—to produce a book neither full enough to satisfy those interested in statistics, nor sufficiently simple to please those who think that Mr. Fisher's fears are justified by the result. The laboratory worker will, as we have said, find the book useful when dealing statistically with small samples, but will not find in it a sufficiently simple and comprehensive account of the general principles of statistical methodology. The illustrations are sometimes—for example, that dealt with on pages 94 et seq.—only illuminating to students with special knowledge of modern genetics. The trained statistician interested in Mr. Fisher's researches will miss a detailed justification of his conclusions, and may resent the somewhat arrogant way in which the law is laid down upon points respecting which there is difference of opinion among persons possibly as well informed as Mr. Fisher. A conspicuous example of this latter failing is the reference to Professor Karl Pearson on page 17. Even if the statement that Professor Pearson's treatment of a fundamental problem contained a "serious error" had not been disputable, and therefore improper in a work addressed to elementary students, it would have reminded anyone of Macaulay's remark on a similar occasion—"just so we have heard a baby, mounted on the shoulders of its father, cry out, 'how much taller I am than Papa!'"

CLINICAL ANATOMY OF THE NERVOUS SYSTEM.

THE volume, *Les Nerfs en Schémas*,⁵ by Professor PITRES of Bordeaux and Professor TESTUT of Lyon, was, as its authors describe in the preface, born of the war. Charged in the early days of war with the duty of instructing students and young graduates in the principles of neurology as applied to war injuries and diseases, they devised a course of instruction intended to be both succinct and practical. The principle of their method was to consider in succession each part of the nervous system, first demonstrating the main anatomical features by means of semi-diagrammatic drawings, and then reviewing the physiology. Following these demonstrations, patients were shown suffering from injuries and diseases of the parts, and especially examples of war wounds affecting the nervous system. Their lessons were therefore at once theoretical and practical, but theoretical considerations were only employed to afford direct explanations of the effects produced. After the war, at the request of many of their students, they decided to put their course of instruction into a permanent form, and the result is the present truly magnificent volume. The lessons must surely have been considerably expanded for purposes of publication, for the great mass of information in the book fills over 706 pages. There are 51 beautiful coloured plates, and 164 drawings in the text, some of which will be familiar to readers of English anatomical textbooks, in which Professor Testut's admirable diagrams have for long figured. These diagrams alone would make the book a valuable possession.

The idea underlying the text is excellent. Early chapters deal with the general principles of nervous anatomy and physiology, the constitution of the neurone, the structure of peripheral nerves, ganglia, etc., and the physiology-pathology of neurone degeneration and regeneration. Then the cranial and spinal nerves, the sympathetic system,

and central nervous system are considered successively, a sufficiently detailed account being first given of the anatomy of each part. Following this the function of each nerve, tract, or centre is described, and then are detailed the main clinical syndromes associated with injury or disease of each. Accounts are given of all important tests of function and methods of examination, such as cerebellar and vestibular tests, and the clinical tests for slight degrees of peripheral nerve palsies. Due attention is paid to the results of recent studies of the anatomy, functions, and clinical syndromes of the basal ganglia. Later chapters deal with the principles of reflex action, including the regulation of muscle tone and the defence reflexes, and the clinical application of this knowledge. For the clinician the arrangement of the book is ideal, and the information is as complete and trustworthy as would be expected from writers of such authority and distinction. It is a volume of permanent value, but it will have to be bound by its owner before he puts it on his library shelf.

BIRTH CONTROL AND MORALS.

To judge by the many books that appear on the subject of birth control it would appear that its advocates are in the ascendant; so that it is well to take notice of what is to be said on the part of those who condemn this propaganda. There has recently appeared such a work by a French author, M. PAUL BUREAU, entitled *Towards Moral Bankruptcy*.⁶ It is a vehement denunciation of neo-Malthusianism. The book has been translated into good English, but even so it is not an example of a restrained and impressive style. For the author indulges in such uncontrolled flights of rhetoric that it is by no means easy to discover what some of his incidental arguments entail. There is, however, no doubt of the main trend of his thesis. The translator must have had an uncommonly difficult task, as is suggested by Dr. MARY SCHARLIEB, who writes an introductory commendation of the work.

M. Bureau proclaims himself a scientist, and no obscurantist. He accepts the doctrines of Malthus, and points out that what is known as neo-Malthusianism was detestable to Malthus. He begins by painting a picture of modern life, which in the luridness of its colours and the horrors of its outlines makes a parallel to the pictures by Hogarth. We must leave citizens of France to tell us if the picture be true or false; it evidently made Mrs. Scharlieb feel ill when she read it in the original, and she confesses so much in her introduction. The picture is worked up with dramatic skill. The results of moral bankruptcy are traced in every failure of trade, discovery, science, art, and citizenship; every default arises from this one cause. M. Bureau's remedy for this danger of bankruptcy is the duty of marriage, and the lasting benefits it confers upon both parties. He believes in the advantages to parents and children of large families; and he also sees that the doctrine of Malthus was true—that population can increase out of all proportion to the food supply. He accepts the preventive check of lack of food, and the positive check of vice, misery, and moral control. If we desire to avoid vice and misery, he urges, there is but one way: "Obviously the continence of the married people is the sole means of correcting excessive fecundity, and outside this means every precaution and every anticonceptionist practice must be condemned." Just as facilities for divorce promote divorce, so, he says, the knowledge of unnatural devices for birth control lead to the possibility of deliberate sterility, for "the child is rarely desired." Again, he writes:

"When in any society several millions of couples have fraudulently ensured sterility in the conjugal relations, how is it possible to speak to young people of both sexes about the strict duty of chastity and purity? how can they be exhorted to marry and found a family? how can the principle of conjugal fidelity and indissoluble marriage be maintained? how can abortion and even infanticide be forbidden? In fact, will these words themselves retain any meaning?"

It would almost seem that such a statement as this were but the climax of a piece of Gallic rhetoric, but it is not; this is what the author really believes, and what he sees

⁵ *Les Nerfs en Schémas*. Par Professeurs A. Pitres et L. Testut. Paris: Gaston Doin. 1925. (Demy 4to, pp. vi + 706; 164 figures, 51 plates. 150 fr.)

⁶ *Towards Moral Bankruptcy*. By Paul Bureau. With an Introduction by Mary Scharlieb, C.B.E., M.D., M.S. Lond. London: Constable and Co., Ltd. 1925. (Demy 8vo, pp. xvi + 555. 16s. net.)

advancing upon civilization, and what will, in his opinion, destroy it. To attempt to refute such an opinion is not possible. There are no sufficient evidences for or against. But when we come to his remedies it is possible to see that he errs. He says:

"We ought to condemn resolutely every plan of sex education in the schools, and far from desiring that this subject of the functions of the organs of generation should become as familiar a branch of instruction as that of the digestion or respiration, we ought on the contrary to leave it alone, since the instinct of generation differs entirely from those of the other physiological necessities."

This conclusion is based upon an assertion that can only be called amazing:

"Sexual instruction would have the great drawback of attracting children's attention to a subject which should on the contrary remain in the background of their general consciousness, and this attention would unquestionably rather suggest possible enjoyments than do any real good. The same thing would happen, as has been proved, in the case of medical students, pupils in midwifery, and hospital nurses. In these professions express teaching is given on the functions of the generative organs and the diseases which affect them; yet these initiated ones furnish a large contingent to the crowd of victims to venereal diseases, and they are too often skilled experts in the art of systematic restriction of natality, and even of abortion."

He states that this "has been proved," but he gives no reference to the evidence upon which this alleged proof is based. It would be interesting to know what it is; without conclusive evidence the statement cannot be admitted. We do not accept his belief that ignorance is the foundation of chastity. But we do endorse his approval of "the fine saying of Tom Mann's: 'The future is for the nations who are chaste.'"

NOTES ON BOOKS.

THE eighth edition of *Public Health Laboratory Work*,⁷ by Professor KENWOOD, deals only with the chemical branch of the subject. It is now no longer possible to include in this handy volume public health bacteriological work owing to the growth of the importance and the range of this subject. The chemistry of public health is dealt with in five parts under the headings of water, sewage, air, food, and disinfectants. All are treated in a comprehensive yet concise manner, and provide the student with the information he requires. Part IV, dealing with food, is probably the most important from the point of view of the future, and its study is to be recommended not only to the student but also to the medical officer of health in practice. The importance of purity in the food supply is now recognized, and local authorities are giving increasing attention to this aspect of public health. The whole book is admirably produced, and the illustrations, including the six plates, with which the book is furnished, materially help in the study of the various processes described.

In a philosophic work, *La Science médicale et sa valeur*,⁸ which by its title recalls M. J. H. Poincaré's *La Valeur de la science* (1908), Dr. L. PRON of Algiers reviews the ever-changing sands of medical opinion in an impartial spirit, and gives many examples of our limitations; for example, in the chapter on non-specific treatment by protein shock he quotes Koteschewer's pyretotherapy, based on the dictum that the essential curative factor is that the remedy should cause fever. Changes of the type of disease—for example, of enteric fever, and of pneumonia and empyema since the recrudescence of influenza—are given. He insists that diseases confined to one organ are exceptional, and that in the case of chronic affections it is almost always impossible to define by one phrase the patient's state. The conclusion, true as it may be, that all human science is ephemeral and that absolute truth as to the origin of life continually eludes our grasp, recalls the lament of Koheleth, the supposed author of Ecclesiastes, that "all is vanity." There is much of interest in this essay, which points out that medicine, being composed of various sciences, is itself a science, but that its practice is an art.

Dr. SNOWMAN'S *Manual of Emergencies* has in its second edition⁹ been reduced in size and printed on thin paper so

that it may be carried in the pocket and be available for all emergencies. The book is based on Lenzmann's work on the subject, and from it are excluded injuries and morbid conditions which are not in themselves dangerous to life. Notwithstanding these exclusions, the ground covered is very extensive; the book begins with epistaxis and ends with asphyxia neonatorum. The emergencies are classed according to the tract in which they occur—the respiratory and the gastro-intestinal, the nervous system, the heart, the urinary organs. Emergencies due to acute poisoning are dealt with, and also those which occur in midwifery. A vast amount of labour must have gone to the compilation of this summary of the diagnosis, pathology, and treatment of dangerous emergencies; and there can be no doubt of the usefulness of the book for refreshing the memory in time of stress. The methods of treatment recommended seem up to date and reasonable; but the pathological description is occasionally cryptic and incomplete. Thus, under the heading of poisoning by alcohol it is said that "alcoholic coma is very apt to be complicated by fracture of the skull or by apoplectic lesions." Insufficient stress would seem to be laid on coma from head injuries, in which the smell of alcohol in the breath is purely incidental—a snare into which many a house-surgeon has fallen.

With the appearance of volume iv of *Collected Papers*¹⁰ the task is concluded of presenting in English form practically all of Professor SIGMUND FREUD's papers up to the time that the translation was completed, including even some which are not contained in the *Sammlungen kleiner Schriften zur Neurosenlehre*. The first eight papers treat of mental processes from the point of view which Freud has described as metapsychological. By this, it is explained in the editorial preface, he means the consideration of a given mental process in what he regards as the most complete manner possible—that is, when treated topographically, dynamically, and economically. The papers in the second part of the volume deal with non-medical aspects or applications of psychoanalysis. At the end of this volume will be found a list of books and papers referred to in the text; a chronological list of papers contained in the four volumes of this series, including also books published by the author; and an index of the contents of volumes i to iv.

The second series of Professor C. ACHARD's clinical lectures at the Hôpital Beaujon¹¹ forms a worthy successor to the previous volume which appeared rather over two years ago (*JOURNAL*, February 23rd, 1924, p. 328). The volume consists of twenty-one lectures dealing with the clinical and pathological aspects of syringomyelia, including Morvan's disease, gout, diabetes, alcoholism, cirrhosis of the liver, sublimite poisoning, nephritis due to lead, and uræmia. The lectures in this, as in the previous volume, are not only richly documented but eminently readable, and should be in the hands of every physician interested in contemporary French medicine.

In September, 1924, Dr. J. J. SIMPSON, Keeper of Zoology, National Museum of Wales, Cardiff, published a little book called *Chats on British Mammals*, which were broadcast from the Cardiff Studio of the British Broadcasting Company, and subsequently appeared in the *South Wales News*. *More Chats on British Mammals*¹² has been introduced to the public by the same novel channels. In book form, with a few necessary illustrations, these ten-minute talks about the habits of British mammals make pleasant reading.

Animals in the Making,¹³ by J. A. DELL, M.Sc., is an introduction to the study of development suitable for elementary classes in biology. It is arranged as a series of practical exercises which do not follow the definite logical sequence, but are arranged in such a fashion as to build upon the elementary facts with which the beginner is likely to be familiar. It appears that the author's method has been practised in schools for eight years, and we are not surprised to hear that this set of well chosen exercises has proved useful.

¹⁰ *Collected Papers*. Vol. IV. By Sigm. Freud, M.D., LL.D. Authorized translation under the supervision of Joan Riviere. International Psycho-Analytical Library, No. 10. London: Leonard and Virginia Woolf at Hogarth Press; and the Institute of Psycho-Analysis. 1925. (Roof 8vo, pp. 508. 2ls. net.)

British Medical Journal.

SATURDAY, MARCH 27TH, 1926.

PROPHYLACTIC VACCINATION OF THE NEWLY BORN AGAINST TUBERCULOSIS.

For the last quarter of a century the prevention of tuberculosis has been a subject of persistent study by clinicians, health authorities, and laboratory workers, and the prospect of success appears to be brighter now than ever before. For some years before the war Professors Calmette and Guérin, in France, had been publishing studies on the attenuation of tubercle bacilli, and in 1913 had established the principle that the bacilli, by a suitable method of cultivation, could be caused to lose their virulence without being deprived of their immunizing power when injected as vaccine. Calmette continued his work at Lille until the German occupation of that city brought it to a close in 1915. His first comprehensive paper on the subject was published towards the end of 1920 in conjunction with Professor Guérin.¹ It dealt with the vaccination of cattle against tuberculosis. By cultivating the bovine tubercle bacillus in a long series of successive passages on a potato medium treated with glycerin and ox bile they obtained an attenuated strain of bacilli not virulent for the ox and monkey, and well tolerated even when injected intravenously in considerable doses. Such an injection of the seventieth subculture into a calf produced a general reaction from which the animal recovered spontaneously after fifteen to twenty days. This result they interpreted to mean that the tubercle bacillus was so modified that it became non-tuberculo-genic, though it remained capable of provoking abundant antibodies and agglutinins. Animals so treated were unaffected by intravenous injections of 3 mg. of virulent bacilli. The conditions under which dairy cattle live, however, and the way in which they naturally contract tuberculosis, prevented any confident conclusions with regard to the efficacy of the protective inoculation against naturally acquired tuberculosis. They therefore made further experiments with calves. The results were decidedly encouraging, and led them to draw the conclusion that the cultivation of bovine tubercle bacilli in series according to the manner mentioned yielded a strain of non-tuberculo-genic bacilli perfectly tolerated by cattle and other animals sensitive to the tubercle virus. These results were published in the paper referred to, and a full account was given in our issue of January 22nd, 1921 (p. 130). Since then the investigation has been continued, and progress reports have been published from time to time. Another full paper, describing the extension of the method to infants, has now been published.² It begins by reporting further results with calves and other animals, including monkeys.

After 230 successive subcultures during thirteen years of a growth on a glycerinated bile potato medium, the organism became so attenuated that it could be injected in the living state in large doses into mammals without giving rise to disease. Experiments showed that such injections rendered animals

resistant to the subsequent inoculation of virulent bacilli. This B.C.G. strain (Bacille Calmette-Guérin), when injected into calves in a dose of 50 to 100 mg., was found to confer upon them the power of resisting the intravenous injection of 5 mg. of living virulent bovine bacilli, which proved fatal to non-vaccinated animals in two months. The vaccine, moreover, was effective not only against experimental but against natural tuberculosis. Experiments on monkeys were equally successful; the vaccinated animals remained well even after living for long periods side by side with non-vaccinated and infected monkeys. In view of the great susceptibility of the monkey to infection these results were clearly very important.

Having got so far as this, Professor Calmette consented to try the method on infants, selecting first those who were being brought up by tuberculous parents or other attendants. The vaccine was administered by the mouth during the first ten days of life, when the bacilli would be absorbed by the upper part of the small intestine. The first human being to whom the method was applied was an infant obliged to live with a tuberculous grandmother. The first dose was administered in July, 1921, and three doses altogether were given at intervals of a few days; no ill effects were noted, and the child remains in perfect health. Since this time numerous infants have been similarly vaccinated, chiefly those born of tuberculous parents, either in France or in the French colonies. The vaccine is given by the mouth in three doses of 10 mg. during the first ten days of life. It can be mixed in a spoon with a little milk and swallowed in the usual way; no discomfort has attended or followed its administration. In the twelve months following July 1st, 1924, 586 infants were vaccinated in France, all of whom were in contact with one or more persons—generally the mother or father—suffering from tuberculosis. By January 1st, 1926, ninety-six of these children had died from various non-tuberculosis causes, and eleven (1.8 per cent.) presumably of tuberculosis. This figure is in sharp contrast with that of non-vaccinated children brought up in similar contact with tuberculous persons, the returns of the French clinics showing that more than 25 per cent. of such children die within the first year of life. The evidence is that the immunity endures as long as the bacilli of the B.C.G. vaccine survive; this is probably about a year, after which it may be necessary to repeat the administration of the vaccine. In animals such repeated treatment has not been followed by any adverse effects, and the degree of immunization was increased thereby both in calves and in the anthropoid apes. It seems possible, therefore, that children would incur no risk, and might be benefited, by an annual repetition of the vaccination treatment.

Although it is too early yet to form more than a tentative opinion of the value of this measure, yet if the results of vaccination in the future are equally favourable 93 per cent. of children of tuberculous parents brought up in a tuberculous environment should be protected. While the results are admittedly incomplete and cannot yet be held to prove the contention of Professor Calmette, there is obviously some indication that prophylactic vaccination of the newly born children against tuberculosis is becoming practicable. The method is now being adopted in many European countries. It appears to be so simple and harmless that during the next few years there should be no difficulty in vaccinating sufficient infants for a positive opinion of the value of this procedure to be obtained. There are, however, limitations to the

¹ *Annales de l'Institut Pasteur*, vol. xxxiv, No. 9, 1920.

² Calmette, Guérin, Nègre, and Boquet: *Annales de l'Institut Pasteur*, February, 1926, p. 82.

method. The vaccine, as has been indicated, must not be given to persons already exposed to infection; hence the necessity, as a rule, of employing it within the first few days of life. Were it by any means found possible, however, to immunize each child systematically immediately after birth, it seems possible to hope that tuberculosis might be reduced to minimal proportions within two or three generations. If, moreover, prophylactic treatment on corresponding lines were applied to cattle the eradication of bovine tuberculosis should also be attainable, and with it the disappearance of a great source of human infection. It is, of course, too soon to build high hopes, but further developments along these lines will be awaited with much interest.

CORONERS' LAW AND THE REGISTRATION OF BIRTHS AND DEATHS.

AMONG the bills now before Parliament the Coroners (Amendment) Bill, introduced in the House of Lords on February 10th by the Lord Chancellor, and the Births and Deaths Registration Bill, presented in the Commons by Mr. Tinne, Dr. Fremantle, Sir Henry Cautley, and Sir Henry Slesser, are of special interest to the medical profession. The second reading debate on the former bill was reported in our Parliamentary Notes last week (p. 549), and the debate on the latter bill in our issue of March 6th (p. 452). Further notes appear in our present issue.

The efforts of the British Medical Association to secure reform in the field covered in part by these two measures were recalled in a leading article on December 12th, 1925 (p. 1134), when we welcomed, in the Coroners Bill as introduced by the Home Secretary at the end of last session, a generous and much-needed measure of reform. As regards the present Coroners Bill there is little to add now to our earlier comments, for it is substantially similar to its forerunner. The clause relating to medical witnesses in the coroner's court has, however, been completely recast, and the result is a great improvement upon the original provision. In particular a clear distinction is drawn between, on the one hand, the medical practitioner who has attended the deceased during his last illness or at the time of death, or, failing any such practitioner, one who is in practice in or near the place where the death occurred, and, on the other hand, the expert witness. The former, under the Act of 1887, is compelled under penalty to attend the inquest and give evidence, and to perform a *post-mortem* examination if directed by the coroner to do so. The latter may be requested to give evidence, and, in addition to an ordinary necropsy, to make a special examination, including an analysis of the contents of the body. It was presumably through an oversight that this distinction was omitted from the original bill. The new clause makes it impossible to compel any practitioner of either class to perform an analysis against his will—a safeguard which the Association has long wished to see established. The general effect of the clause, together with the modifications carried out in the relative section of the Act of 1887, is to allow the coroner to secure and pay for such medical assistance as he may desire in the course of any inquest, and to procure and pay for the performance of a *post-mortem* examination as a preliminary to deciding upon holding an inquest. Unfortunately the Home Office has stopped short of the logical completion of the procedure contemplated, for it has failed to provide for a detailed medical report as a necessary preliminary to deciding

upon an inquest in all cases where the cause of death is not patent. In general, any minor alterations in detail in the new bill are all to the good. This is particularly so in the provision by which the new superannuation rights are to attach to part-time as well as to whole-time coronerships. The one great defect of the bill remains, however. This is the almost inconceivable parsimony by which the remuneration for performing a *post-mortem* examination and attending to give evidence in court is left, for the practitioner under statutory obligation to render these services, at the sum fixed in 1887—namely, two guineas. The fee of the voluntary witness is a matter for individual agreement.

The Coroners Bill is due for report in the House of Lords, and its progress is being carefully watched by the British Medical Association with a view to securing, at a later stage, certain amendments—notably in the case of the fees mentioned above. The story will not, however, be complete until the rules to be made by the Lord Chancellor with the concurrence of the Home Secretary have been published. In them we may hope to find some regulation of the procedure of a court in which the arbitrary powers of the coroner have too often given rise to grave abuse.

Coroners' law is essentially one section of the general law covering all the machinery for ascertaining and recording the cause of every death, and it was hardly an unreasonable hope that the present Government would deal with the whole matter on a broad and statesmanlike basis. That hope has not been fulfilled. The Births and Deaths Registration Bill is a private member's bill, and as such necessarily excludes any proposal involving a call on the public purse. It follows that it must stop short of what has been generally recognized, since the report of the Select Committee on Death Registration as long ago as 1893, as the only adequate basis for a system of registration. That basis is the compulsory medical certification on a statutory form, and after personal inspection of the body by the certifying practitioner, of every death and every stillbirth as an essential preliminary to registration. In this respect the present law is in the first place unjust, in the second wholly inadequate. It is unjust because it imposes on any medical practitioner who has attended during the last illness an obligation to certify a death without remuneration. It is inadequate because it does not require inspection of the body—that is, verification of death—by the certifying practitioner; it makes no provision for the certification or registration of stillbirths; and it allows registration of a death without medical certification. The last-mentioned defect is partly balanced by the rule of the Registrar-General which ensures that all deaths not medically certified shall be reported to the coroner before registration. This arrangement clearly makes for safety, but can hardly be considered to meet the needs of the case. The present position as regards registration of uncertified deaths is indicated by the following figures recently quoted by the Minister of Health, Mr. Neville Chamberlain, in the House of Commons: Out of a total of 473,006 deaths registered in England and Wales last year, 435,494 were registered on medical certificate and 32,701 on coroner's certificate, and 4,811 after report to the coroner but without medical certification or inquest.

It is clear that the inadequacy of the law can only be corrected by the removal or the intensification of the injustice, for the requisite system of certification would increase the statutory burden upon the medical profession. Apart, therefore, from the second alternative, the only comprehensive remedy yet suggested

must entail expenditure. The promoters of the amending bill are thus much in the position of the lady who was permitted to bathe on condition that she did not go near the water. It must be added that within the limits indicated they have produced an ingenious and useful measure. Accepting at once the desirability and impossibility of provision for universal certification after inspection of the body, they have provided that the certificate shall be upon a statutory form, and that local authorities may provide for the inspection of the body by a registered medical practitioner, upon the request of the coroner, in any case where the body has not already been seen by the certifying practitioner. If local authorities take action under this clause it will be seen that a strong incentive to the relatives to secure medical inspection of the body prior to certification in every case will be supplied. Those who request the inspection will, of course, have to pay a fee for it, since the statutory obligation of the certifying practitioner is not extended to include this duty.

The medical profession, if not the general public, has long desired a system of confidential certification of the cause of death. While this object is not attained by the present bill, a step is taken in that direction; for it is provided that the certificate shall in future be delivered direct to the registrar by the certifying practitioner, a statement to the effect that the certificate has been signed being handed to the relative, who, in turn, must deliver it to the registrar. It will be seen that this proposal would slightly increase the obligation at present resting upon the certifying practitioner. Sir Richard Luce, at the suggestion of the British Medical Association, gave notice of an amendment by which it was proposed to secure that the delivery of the certificate should be by post and free of expense to the sender. As regards the question of stillbirths, no additional obligation is laid upon the medical profession, but it is provided that all stillbirths shall be registered on the information of the person who would, had the child been born alive, have been required to give information concerning the birth under the Births and Deaths Registration Acts. The information is to include either a written certificate from the practitioner or midwife who attended at the birth or has examined the body, or else a statutory declaration that no such person was present or that his certificate could not be obtained. The disposal of the stillborn child in any burial ground is made conditional upon the production of a certificate of registration from the registrar. Why a similar safeguard is not included against the private disposal of a stillbirth we fail to understand. For the rest, provision is made for increasing the efficiency of the burial regulations on the lines laid down in 1893, and to prohibit the removal of a body abroad without due notice. If the bill would not accomplish much, it would, if passed, at least pave the way for more.

There remains one point, covered by neither of the bills under debate, which might with equal propriety have been included in either. At present the duty of the certifying practitioner is clear so long as he is able to sign the prescribed certificate; beyond this it remains in doubt. While there is a fairly general practice of communicating with the coroner where a certificate is refused, the law is as yet silent upon the point, and this occasionally gives rise to unfortunate misunderstandings. Among the amendments which the British Medical Association is seeking to secure in the Births and Deaths Registration Bill is one which supplies this deficiency by the insertion of a clause

requiring medical practitioners unable to certify in certain specified cases to report the circumstances forthwith to the coroner for the district in which the death has occurred. It may be added, for the satisfaction of any reader who has procured a copy of the Births and Deaths Registration Bill, that an amendment has been tabled whereby the word "not" will be inserted in the definition of a stillbirth which, as at present drafted, makes the terms "stillborn" and "stillbirth" apply to any child born alive.

THE MEDICAL PUNDITS: A QUIET MONTH.

NOTWITHSTANDING many requests from our readers for more, we have so far been unable to give further samples of the kind of public enlightenment now known in London as "medical punditry." For one reason or another the torrent seemed to dry up immediately after the appearance of an article on this subject in the JOURNAL of February 27th. Some dreadfully sharp things about "old-fashioned views on health propaganda" have been said by favourite organs of popular instruction, but diligent search through the press cuttings has yielded no *obiter dictum medicum* worthy of quotation. A month has passed without a word in season on, for instance, the hidden peril of the sock suspender, or on lipsticks and the future of the race—nothing but humdrum advice on how to keep fit. There may be a revival on the first day of next month, but we are not too confident even of this. We note, however, that March is not a close season for medical portraits in the lay press, and that the difficult and painful duty of baiting the General Medical Council has not yet gone out of fashion. It is plainly better to help along the public confusion about the General Medical Council and the British Medical Association, and about the difference between legitimate and ridiculous health propaganda, than to spend a whole month out of the public eye.

THE UNIVERSITY OF LONDON.

THE Report of the Departmental Committee of the Board of Education on the University of London,¹ though it completely discharges its terms of reference, is really of the nature of an interim report. The Committee was instructed to indicate the "principal changes now most needed in the existing constitution of the University of London and on what basis a Statutory Commission should be set up to frame new statutes for the University." The Committee, therefore, has confined its recommendations to general principles, and has not attempted to indicate how they should be applied. It has, as a matter of fact, directed its attention in the main to financial matters. The third statute of the University provides that it shall "hold forth to all classes and denominations, both in the United Kingdom and elsewhere without any distinction whatsoever, an encouragement for pursuing a regular and liberal course of education; to promote research and the advance of science and learning; and to organize, improve, and extend higher education within the appointed radius." The anomaly in this relation is that the University itself has practically no financial resources which it can devote to the development of teaching or research, except the balance of examination fees. Yet the total income for the year 1923-24 of the twenty-two schools of the University in receipt of grants from the Treasury amounted to nearly £1,000,000, of which about £350,000 represented recurrent grants from the University Grants Committee, and about £70,000 aid from the London County Council. (In 1924-25 the amount allotted by the University Grants Committee

¹ Report of the Departmental Committee on the University of London. Cmd. 2512. London: H.M. Stationery Office, or through any bookseller. Price 1s. 3d. net.

was £377,695, and by the London County Council £78,366.) The University Grants Committee, in its last report, after expressing its desire not to impair the autonomy of the universities or to diminish in any way their sense of responsibility, states that with this aim in view it has sought that the money provided by the Treasury should be given as block grants in aid of a university's general income, and that it should remain with each university itself to decide in what precise way its income, including the Government grant, should be distributed, "for without the control of finance there can be no effective control of policy." This principle has not been applied to the University of London, but separate grants are paid for the central administration of the University and for each of its corporate colleges, and for its twenty schools, eleven of which are medical schools. Though the University Grants Committee recognized that there would be strong resistance to any proposal to devolve the allocation of the Government grant among the different colleges and schools upon the supreme governing body of the University of London, it nevertheless regarded it as clearly unsatisfactory that the University of London is in no real sense master in its own house or capable of enforcing a policy of its own. The Grants Committee stated that it seemed clear to it, "looking at the matter from the outside, that until the central authority of the University has become a reality it will be impossible for Parliament, the London County Council, and the general public, to feel certain that the fullest and most economical use is made of the vast aggregation of teaching power contained in its numerous constituent bodies." The Departmental Committee has been largely guided by this opinion, and in order to carry it out has recommended the establishment of a Council of the University to control finance, and in particular to have final authority in the allocation of university grants, subject to the right of the Senate to report. This is, in fact, the central recommendation of the Departmental Committee, and that about which there will probably be most difference of opinion. The nature of this difference is disclosed in a minority report by Mr. H. B. Lees-Smith, M.P., who considers that the Senate should be supreme in finance as in other matters. He approves the constitution of the University Council suggested by the Departmental Committee, but recommends that it should be a finance committee or council of the Senate. The Departmental Committee recommends that a large Senate should be retained, and that in addition to the standing committees already existing there should be a Collegiate Council consisting of the Vice-Chancellor, the Principal, members of the Senate appointed by the chief institutions in London, and the two members to be appointed by the medical schools, but with power to the Senate to add others. The Collegiate Council would advise the Senate on institutional and interinstitutional matters. What has been written here is intended only to afford a general idea of the report. The reasons it gives for the recommendations mentioned, and for certain others which we are obliged to omit, will call for very careful consideration.

CLEAN FOOD.

At the Liverpool Congress of the Royal Sanitary Institute in 1924 a committee was established to consider common methods of food handling in this country, and "to approach the Minister of Health with a view to urging upon him the amendment of the existing legislation and the provision of new laws governing the preparation and sale of food, and ensuring its proper cleanliness and freedom from contamination." This committee, having drawn up its report, attended at the Ministry of Health on November 15th, 1925, and were received by Sir George Newman and other

officers of the Ministry. Sir George Newman, in welcoming the deputation, expressed the regret of the Minister of Health that he was unable to receive the members personally, and stated that the Minister fully appreciated the points made by the committee. He assured the committee that its suggestions would be carefully considered, and expressed the view that one of the principal factors likely to lead to improvement was the education of the public in the need for greater care in the handling of food. Local authorities now had power to incur expenditure in publicity regarding health matters, and Sir George Newman thought that this was a subject which might well be considered suitable for such publicity. The institute, he added, could help to bring the question under the notice of local authorities by publishing a number of papers on a cleaner food supply. The council of the Royal Sanitary Institute adopted this suggestion, and has published a pamphlet entitled *Clean Food*,¹ embodying the information collected by a committee appointed jointly by the institute and the Society of Medical Officers of Health. The council hopes thus to stimulate the interest of local authorities and the general public in this important question of cleanliness in the handling and preparation of food, and to the necessity for compelling those concerned in any way in the distribution or sale of food to take precautions against its contamination. The pamphlet consists of an introduction by Dr. Charles Porter on "The public and food hygiene" and a number of monographs on particular aspects of the subject. Thus Dr. Orr writes on milk, Dr. Cates on bread and confectionery, Sir Wilfred Beveridge on groceries, Dr. Fenton on fruit and vegetables, Professor Kenwood on fish, Dr. Willoughby on imported foods, Dr. Naylor on premises where food is prepared, and Dr. Allan on restaurants and cafés, and on the food regulations, licensing, and registration of premises in other countries. These papers certainly contain abundant evidence that in connexion with the treatment of food and its transport and exposure for sale there are very many opportunities of contamination, and there is a strong argument for further powers enabling local authorities to exercise fuller control. It should prove a valuable document from the publicity point of view because of its authoritative exposure of existing unhealthy conditions and because it points the way to reform.

PUBLIC HEALTH LABORATORY WORK IN AUSTRALIA.

Public health laboratory work in Australia has recently been organized on a comprehensive scale, as is shown by the account given in Service Publication No. 27, entitled *The Commonwealth Health Laboratories*.² A special division of the Commonwealth Health Department was started four years ago to administer laboratory services, and a beginning has been made by the establishment of eight laboratories in different regions of Australia. The functions of these laboratories are the examination of clinical specimens from the district served by the laboratory; investigations to assist public health work, such as the bacteriological and chemical examination of food, milk, and water; the investigation of any epidemics of disease occurring within the district wherein the laboratory is situated; the installation and utilization of special apparatus for public health purposes, such as x-ray plants. These laboratories are provided with a thoroughly up-to-date equipment, sufficient to meet all expected requirements, and extra apparatus is promised for special work if required. A nucleus of a library has been provided and is supplemented periodically, and a good selection of journals is

¹ *Clean Food*. Published by the Royal Sanitary Institute. February, 1926. Price 2s. net.

² *The Commonwealth Health Laboratories*. By W. C. Sawers, D.S.O., M.B., D.T.M. (Minister for Health). Commonwealth of Australia: Service Publication No. 27.

also taken by each laboratory. The personnel usually consists of a medical officer in charge, a technical assistant, and a laboratory boy. All work for charitable institutions, for Government medical officers, Government health officers and medical officers of health, and for patients attending the Commonwealth tuberculosis and industrial clinics, is performed free. A fee is charged for work carried out for private practitioners, and the scale of fees appended to this report shows that these are roughly the same as those charged by the recognized laboratories established in this country. A description is given in the pamphlet of the buildings used for health laboratories. The photographs of the exteriors, interiors, and various outhouses, such as the animal house, give the impression of excellently designed institutions. Though they have only been established four years these laboratories have already proved indispensable units in public health work, and have become a great help to medical practitioners. Future developments in the health service of the Commonwealth will probably be accompanied by an expansion of the laboratory service.

COMBATING TUBERCULOSIS IN SWITZERLAND.

Two campaigns, one of them against alcoholism and the other against tuberculosis, are at present interesting Switzerland. The *Journal de Genève*, one of the leading Swiss newspapers, has been devoting columns almost daily to these two subjects; while it admits that the mortality statistics in respect both to alcoholism and tuberculosis have improved during recent years, it asserts that the improvement has not been so marked in Switzerland as in some other countries, such as France and Czechoslovakia, where conditions are fairly comparable. In the case of alcoholism the first line of action of the Swiss authorities has been directed to raising the price of spirituous liquors. A more thoroughgoing offensive is now being taken against tuberculosis. The Federal Council of Switzerland has framed proposals for dealing with it, and the proposals have already passed one of the houses of parliament, the Council of States, and will come before the other, the National Council, at the approaching session. The most important of these proposals, and that which has aroused the most discussion and in some quarters vehement objection, is the requirement of compulsory notification. It is urged by the Federal Council that compulsory notification is a necessary condition of effective action. The argument, with which we are very familiar in this country, is used that unless there is machinery for discovering the victims of tuberculosis the efficacy of any antituberculosis measures must be greatly impaired. It is held that though tuberculosis is not like an ordinary epidemic infectious disease, nevertheless every tuberculous person must be regarded as a potential focus of dissemination, and while he need not necessarily be segregated certain measures of precaution must be applied with regard to him. The Federal Council also points out that compulsory notification has been adopted by all States which have seriously set themselves to combat tuberculosis, and that this measure obtains even in France, in spite of popular misgiving or hostility. It is promised that elaborate precautions will be taken to ensure the secrecy of all such notifications by the authorities, and, indeed, only on the condition of such secrecy can the proposal be made with any hope of popular acceptance. The measure will be administered, not by the Federal Government, but by the cantonal and communal authorities, largely through the tuberculosis dispensaries which already exist. The Federal Council recommended the establishment of institutions in which cases of tuberculosis could be lodged and treated; that special arrangements should be made for medical inspection and for

prophylaxis in schools; that scientific research in tuberculosis should be encouraged; and that certain hospitals should be subsidized. The shape of the new measure has been altered and its provisions curtailed in some respects in passing through the Council of States; in particular the original proposals of the Federal Council have been reduced in respect to the establishment by the State or by local authorities of buildings for the reception and treatment of tuberculous persons, the Chamber having a jealous eye upon the public purse. It remains to be seen whether the measure is further whittled down in passing through what corresponds in Switzerland to the House of Commons.

THE PINEAL GLAND.

At a recent meeting of the James Mackenzie Institute for Clinical Research, St. Andrews, Professor Herring, after alluding to the numerous theories which had been put forward by anatomists and philosophers as to the function of the pineal body, gave a brief account of the comparative anatomy and histology of the organ in the various types of vertebrata from the elasmobranch fishes upwards. It is one of a series of structures associated with the roof of the third ventricle. Its construction and morphology suggest a secretory function; it has a distinct nerve supply. Originally its cavity communicated with the cerebro-spinal canal, but as development advanced it was shut off from this connexion and became apparently an organ of internal secretion. At one stage, in some of the lizards, it is associated with the appearance of a mesial eye, but the structure of this and its nerve supply are distinct from those of the pineal gland itself. In the higher mammals, in whom the gland is shut off from the cerebro-spinal canal, there is found immediately behind the pineal recess, and lining the ventricular surface of the posterior commissure, a mass of definite glandular epithelium, which is almost certainly secretory. The pineal body itself consists mainly of cells with characteristic club-shaped processes, and tumours of the gland are found to be either teratomata or pinealomata composed of these characteristic cells. Clinically tumours of the gland appear to be associated with precocious sexual development. Experimental physiology has yielded contradictory results, but certain experiments based on feeding with the gland substance have produced precocious sexual development in young males; in females the results were negative. Extirpation experiments are extremely difficult on account of the vascular relations, most animals dying of haemorrhage. Transplantation has never been successful. The posterior lobe of the pituitary body, the lecturer pointed out, resembles the pineal gland in its relation to the cerebro-spinal fluid system.

THE SCENT OF FLOWERS.

We had not imagined that there was to be found such a depth of philosophy in the relation of the olfactory nerves to odorous substances as has been found by Mr. F. A. Hampton and discussed in his book entitled *The Scent of Flowers and Leaves*.¹ The comparable qualities of odours and their connexion with memory have received so little general attention that astonishment may be caused by some of the author's assertions, but reflection or the test of experiment brings realization of their truth. Comparisons of the odours produced in nature with those of the single constituents which compose the natural scent lead to the recognition of effects which he has aptly named "over-tones." His treatment of the subject embraces chemical and physiological views, but his exposition is enriched by the fact that he writes as a botanist of wide knowledge. Many

¹ *The Scent of Flowers and Leaves*. By F. A. Hampton, M.A., B.M., B.Ch.Oxon. London: Dulau and Co., Ltd. 1925. (Cr. 8vo, pp. vii+133. 6s. net.)

scents exert an antiseptic action on behalf of the plant, and came to be employed by mankind at an early period on account of that property. Sprigs of rue and rosemary used to garnish the Old Bailey under the idea that they would act as a protection against gaol fever. Effective description must ultimately be founded on a scheme of characterization permitting of assortment by similarity into groups. Here has been the author's most difficult task. It presents the same kind of obstacles as confront the attempt to correlate physiological action with chemical constitution. Idiosyncrasies, multiplied until they are almost generalities, and habituation tending in some cases to acute perception, in others to oblivion of sense, work havoc among orders of arrangement of scents by their effects. We may instance the scent of the bloodhound for a footprint or the acute perception of human beings for an infinitesimal quantity of musk. Again, it is generally believed that the camel can smell water, and certainly many things possess the essential character necessary to the exhalation of an odour which are hardly perceptible or quite imperceptible to the human sense; we need only mention the instance of growing grass, in contrast with the change into the scent of new-mown hay. Notwithstanding these difficulties Mr. Hampton has produced for scents a system of grouping which appears valid, and if his arrangement is not final, yet his scheme has an engaging interest, and may prepare the way for a further development of the study. There is an interesting chapter on the relation between the scent of flowers and that of certain moths, showing the parts reciprocally played in fertilization. The author has something to say on the scent of flowers in the house, from which we extract the remark, "All scented flowers are out of place on the dinner table, and if the reader doubts it let him imagine the combination of lobster and hyacinth." Even those who lack a general interest in the subject might well read this book for the instruction it gives on the choice of scented flowers for the garden.

THE ARMY MEDICAL SERVICE IN FRANCE.

At a meeting of the Academy of Medicine on February 16th, the eminent French surgeon, M. Tuffier, submitted a communication containing suggestions for the reorganization of the army medical service, with a view to establishing closer co-operation between the military and civil medical profession. He pointed out that the absence of a suitable liaison at the commencement of the war led to many mistakes and was the cause of fatal results in a considerable number of wounded men. His suggestion is that the number of regular medical officers should be reduced from 1,710, the number previous to the war, to 1,011, and that the medical duties in the army in time of peace should be distributed amongst the regular medical service, the reserve medical officers (in other words, civil medical practitioners), and medical students in their final year. He would employ the junior ranks of the regular service in the garrisons of Morocco, Southern Algeria and Tunisia, and the Levant, where they would have experience of active military service, and employ local civil practitioners of the army medical reserve in the large centres of population where there are troops. The medical students would be similarly employed, and in all cases the civil reserve so employed would be granted rank and promotion up to that of surgeon-general in the same way as officers of the regular army medical service. In this way he considers that economy in the budget would result, that the regular medical officers would have practical experience of field service, and that the civil medical practitioners would obtain technical knowledge of military requirements which would enable them to adapt themselves rapidly to their

duties in the event of mobilization. M. Tuffier's proposal was referred to a committee of thirteen members of the Academy of Medicine, including amongst others the well known names of Vaillard, Sieur, Dopter, Delorme, Vincet, and Tuffier himself. The suggestions do not apply to the medical services with French colonial troops, but only to medical services of what is called the metropolitan army for service in France, North Africa, and Syria. It is interesting, however, to know that the leading authorities in the French medical profession are urging a closer liaison between the regular army medical officers and their brethren in civil practice, with a view to more effective amalgamation on mobilization than existed on the outbreak of war in 1914. In this respect the French Academy of Medicine is taking steps similar to those which have engaged the attention of the British Medical Association for some time past.

THE COMING OPTICAL CONVENTION.

THE third Optical Convention will be held under the presidency of the Astronomer Royal, Sir Frank Dyson, D.Sc., F.R.S., at the Imperial College of Science and Technology, South Kensington, during the week commencing April 12th. The first Optical Convention was held in 1905 under the presidency of Sir Richard Glazebrook, and the second, under that of the late Professor Silvanus Thompson, in 1912. Very notable advances have been made in Great Britain since the last convention, and these will afford ample materials for debate. Each day of the week will be occupied by the discussion of subjects of an optical character, including ophthalmology, astronomy, microscopy, photography, and cinematography. The president will deliver an address, and special lectures including some of a popular character, accompanied by demonstrations, will be given. An exhibition is being arranged in three sections—experiment and research, historical, and commercial. The scientific proceedings will be recorded in a volume which will be supplied to Class B members, who subscribe £1 11s. 6d. Class A members, who will be admitted to all the proceedings of the convention and will receive a copy of a catalogue of the instruments and apparatus shown, pay 15s. A special entertainment committee has been appointed; it is arranging for optical demonstrations, and also for dramatic performances, to be given by the students of the Royal Academy of Dramatic Art. The performances are being so arranged as to afford opportunities for optical illusions and special stage effects produced by optical devices. Full particulars of the convention can be obtained from Mr. Thomas Martin, 1, Lowther Gardens, Exhibition Road, S.W.7.

EDINBURGH is about to lose the services of Dr. B. P. Watson, professor of midwifery and diseases of women, who has accepted the corresponding chair in Columbia University, New York, and the directorship of the Sloane Hospital for Women.

THE Egyptian Council of Ministers has appointed Sir E. Cooper Perry Director of the Faculty of Medicine for three months from the beginning of October next, with the view of organizing that faculty in the newly established University of Cairo. The selection of Sir Cooper Perry and his acceptance of the invitation appear the more appropriate in that twenty-nine years ago he went out to Cairo to organize the medical school and hospital there at a time when it was difficult to induce Egyptians to study medicine in numbers adequate to the needs of the country.

THE OSLER MEDAL.

IN the BRITISH MEDICAL JOURNAL of June 20th, 1925 (p. 1133), we gave an account of the ceremony in connexion with the unveiling of a bronze plaque in memory of Sir William Osler, Bt., F.R.S., M.D., F.R.C.P., in the Court of the University Museum at Oxford. The plaque was presented to the University on behalf of the subscribers to the Sir William Osler Memorial Fund by the President of Magdalen, and was unveiled by the Vice-Chancellor.

By a decree enacted in Convocation on May 19th, 1925, the University of Oxford gratefully accepted the fund subscribed in memory of the late Regius Professor of Medicine, and made a number of regulations for its administration. One of these declared that a bronze medal should be awarded once in every five years "to the Oxford medical graduate who shall, in the opinion of the Board of Awarders hereinafter constituted, have made the most

valuable contribution to the science, art, or literature of medicine, and who has not previously received the medal." By another regulation the Board of Awarders was constituted as follows: The Vice-Chancellor; two professors of the Faculty of Medicine elected by the Board of the Faculty of Medicine; two persons not being members of the University, elected by the Hebdomadal Council on the recommendation of the Board of the Faculty.

The first quinquennial award of the Osler Medal was appropriately made last year to Sir Archibald E. Garrod, K.C.M.G., F.R.S., D.M., F.R.C.P., Regius Professor of Medicine in the University of Oxford, Student of Christ Church, and consulting physician to St. Bartholomew's

Hospital and the Hospital for Sick Children. The accompanying illustration shows the obverse and reverse. The medal has been executed by Mr. F. Bowcher, whose name appears thereon.

PRINCIPLES OF TREATMENT IN DISEASES
OF THE NERVOUS SYSTEM.

THIRD LETTSOMIAN LECTURE.*

IN his third and concluding Lettsomian Lecture, delivered at the Medical Society of London on March 15th, Dr. E. FARQUHAR BUZZARD considered principles of treatment in relation to conditions in which disorders of function, possibly accompanied by physical or chemical changes as yet unexposed, demanded attention. He contended that prevention and adaptation must again receive their due, and both must largely rely for their efficacy on anticipation, as well as early recognition, of morbid symptoms.

Head Injuries.

The particular type of head injury discussed by Dr. Buzzard was that in which a blow on the cranium resulted in a period of unconsciousness, short or long, unaccompanied by any serious defect in the bones of the skull. The period of unconsciousness was attributed to concussion, and its importance as evidence of injury to the brain was often too lightly assessed compared with the attention paid to a fracture of the skull. It had to be remembered that the brain was a very delicate and, sometimes, important organ, whereas the cranial bones only served a useful purpose in that they helped to protect the brain from direct injury. The difficulties experienced in carrying out preventive treatment were often provided by the patient, who either refused to regard his accident as in any way serious, or who, having been x-rayed and assured that there was no fracture of the skull, took no interest in what might have happened inside it. How long a period of complete rest should be insisted on was not easily decided. During the war, when many of these patients were under military discipline, he had saved himself much trouble, and the victims of head injuries such as he was describing much suffering, by ordering as a routine measure a month in bed. In civil practice that was not always possible, and the amount of rest might reasonably be regulated by taking into account the extent of amnesia, especially of the retrograde variety, disclosed by the patient, and also of the severity of the symptoms immediately following the accident, the period during which the patient was dazed, confused, or exhibited the symptoms placed under the category of cerebral irritation. In any case, resumption of activity should be gradual, and could usefully be employed as a test for the adequacy of the rest which had been enforced. There could be no alternative treatment, and its simplicity was its chief and only objection. As an adjunct a dose of

bromide, 10 or 15 grains, should be given twice daily, partly in order to allay restlessness and depression, partly as a prophylactic against possible epileptic tendencies. It was even desirable that that medicinal precaution should be persevered with for some months after active life had been resumed, and the success of the treatment outlined was much more likely to be achieved if the patient was frankly told that the measures were necessary not so much for symptoms which were present but in order to prevent months of suffering in the future. The patient who had neglected to seek advice for weeks or months after injury and who came for assistance in the condition of post-concussional headache complicated by anxiety neurosis would require more lengthy rest in bed, and perhaps more secluded, than that already referred to; the administration of suitable sedatives and analgesic drugs; and the application of psychotherapy appropriate to his individual anxiety or anxieties. In contrast to the concussion effects described a not uncommon sequel was the condition known as "contusion headache," which might occur as a separate entity, though not seldom it complicated the concussion picture, so that the patient suffered from both conditions at the same time. In an uncomplicated case the skull might or might not have been cracked by a blow, but there might be no evidence of a depressed fracture indicating the necessity for immediate operation. On resumption of his ordinary duties the patient found that he was subject to severe headaches, the bouts of pain being clearly excited by physical exertion. The pain was generally described as like toothache in character, and each bout was not often of more than a few hours' duration. Frequent recurrence and severity were, however, sufficient as time went on seriously to interfere with the patient's activities and pleasures; whilst not very infrequently they gave rise to mental disturbances amounting to maniacal outbursts or melancholic depression. Whilst in some cases a period of complete rest might suffice to give relief, in others rest failed, and an operation was the only measure calculated to cure the patient. The operation was a simple one, the object, according to Mr. Trotter, being to decompress at the site of injury and so to establish a more normal circulation in the bruised tissues exposed to view by the opening in the skull. Resolution, long delayed, took place, the headaches ceased, and, if thought desirable at a later stage, the gap in the bone might be closed by a bone graft or other mechanical means.

Traumatic Neurasthenia.

Under this heading Dr. Buzzard contended that experience indicated that the term was applied chiefly to two large groups of cases, both of which presented almost

* A report of Dr. Farquhar Buzzard's first lecture appeared in the JOURNAL of February 20th (p. 333), and the second is reported in the issue of March 6th (p. 435).

constant clinical characteristics. The first group comprised those who had sustained an injury to some part of the body—more frequently, though not necessarily, the head—of varying severity; the second group was of smaller dimensions, and its members walked into the consulting room leaning forward on a stick grasped in one hand, with the other placed over the lower part of the back. The practitioner knew at once that the site of the injury—a strain or blow—was the spine. There were two points in connexion with both groups which could not be overlooked. Neurasthenic symptoms were not the monopoly of patients who had sustained injuries to the head or even to the spine; on the other hand, it was not unreasonable to suppose that the awe with which an injury to the skull or spine was popularly regarded might suffice to account for the frequency with which such injuries were followed by the development of an anxiety neurosis. In the second place, there was no constant relationship between the severity of the trauma and the incidence of the neurotic sequelae, but it was not without significance that injuries resulting in total disablement were rarely complicated by the anxiety features of traumatic neurasthenia. Reviewing accidental injuries and their consequences generally, it was impossible, said Dr. Buzzard, to avoid the conclusion that the factor common to the great majority of cases of traumatic neurasthenia was the knowledge that the responsibility for the trauma could be placed on shoulders other than those of the victim—on the employer, or on a corporation, or the State. Traumatic neurasthenia was rarely met with among persons the responsibility for whose injuries could not be relegated elsewhere. Nevertheless, there were other factors contributing in many cases to the development of the anxiety neurosis. Dr. Buzzard contended that it was the business of the medical man to exercise an intelligent anticipation of the early signs of traumatic neurasthenia, with a view to checking further developments. When the condition was established there must not be underestimation of the difficulties in the way of successful treatment, least of all that which concerned responsibility. It had already been recognized to some extent in the admission often made that the first step towards a patient's recovery would be the settlement of his claim. That admission was generally interpreted as evidence of what might be expected from the satisfaction of a greedy desire, but Dr. Buzzard ventured to think that the shifting of responsibility for the patient's recovery on to his own shoulders played at least as important a part in the subsequent history of the case.

Modern Psychotherapy.

Although the whole subject was still in its scientific infancy and still unable to control its emotional tendencies, Dr. Buzzard thought the time had come when it might be profitable to consider, and perhaps to define tentatively, the scope of psychotherapy. In order to clear the deck, as it were, for psychotherapy, it might be well to agree, perhaps, that all patients whose symptoms were frankly hysterical were fit subjects for the art of psychotherapy in the form of suggestion, education, or investigation. It rarely occurred that a patient was sent to him with the diagnosis of "anxiety neurosis," and never did one come with the diagnosis of manic-depressive psychosis. Both groups arrived with the label of "neurasthenia" hung over their blushing necks. That sounded of professional knowledge, but it was a knowledge of contradiction. How many doctors realized that among their neurasthenic patients were a number of examples of the milder forms of the manic-depressive psychosis? How many realized that those were the "neurasthenics" who wore their patience to its last thread, and yet invariably recovered? How many doctors and how many of such patients realized that the treatment prescribed had nothing to do with their recovery? Diagnosis was a matter of great importance in regard to treatment. The manic depressive was made worse by any systematic form of psychotherapy involving mental probing and investigation. The anxiety neurotic could not be cured without the employment of some such method of treatment. The only psychotherapy permissible for the depressive patient was the sympathetic encouragement and the daily audience of his woes, together

with the provision of a sufficiency of rest, food, and sleep. Lest there should be any misunderstanding Dr. Buzzard emphasized the fact that his remarks referred only to the milder forms of the manic-depressive disorder.

Time did not permit of the discussion at length of the principles governing the use of psycho-analytical methods in relation to all functional disorders, and Dr. Buzzard confined himself to brief reference. Many cases of phobia certainly received benefit; some were permanently cured by such treatment; and rarely did harm result. On the other hand, patients suffering from compulsion neuroses were less certain quantities, and it was probable that faults in the technique of analytical methods might be responsible for some disastrous results. Experience would probably eventually teach how the technique could be improved in order to ensure more universal success. A question which had interested Dr. Buzzard for some time was whether spasmodic torticollis was a functional disorder in the sense that it could be cured by any psychotherapeutic measures, and he was bound to confess that had not yet been answered to his satisfaction. So obstinate was it to all other methods of treatment that further efforts on psycho-analytical lines should be encouraged so long as the evidence of harmful results was not forthcoming. Occupational neuroses might perhaps be placed in the same category, although the speaker entertained grave doubts whether in a severe case of writer's cramp, for instance, any cure was possible in the sense that the patient could return with impunity to his scriptorial excesses.

Summing up, Dr. Farquhar Buzzard said practitioners and students alike were appalled by the ever-growing mass of facts and theories in which the art of medicine was involved, and by the hopelessness of attempting to keep pace with advances in all branches. It was inevitable, therefore, that each must turn more and more for guidance to principles based on sound physiological, psychological, and anatomical foundations, and that students of to-day and the years to come should never fail to master them even at the expense of much detailed knowledge of disease, for on such foundations the knowledge of disease could easily be built up. Without them no wealth of experience could ever produce the type of medical man who would lift the profession to a position in which it might secure and hold the trust and confidence of the public.

ROYAL MEDICAL BENEVOLENT FUND.

At the last meeting of the Committee forty-eight cases were considered and £629 voted to forty-two applicants. The following is a summary of some of the cases relieved.

M.B., married, who graduated in 1882, has been an invalid for twenty-five years and has the constant attention of his wife. Their total income amounts to £156 per annum, and the house they live in is their own. Voted £30 in twelve monthly instalments.

Daughter, aged 58, of L.R.C.P. and S. who died in 1878. Applicant has been a nursery governess and mother's help, but is now only able to do very light work. She is at the end of her resources. Friends gave her some help. Voted £18 in twelve monthly instalments.

Widow, aged 69, of M.B. who died in 1884. Husband had been in receipt of a grant four months prior to his death. Applicant is at present living with her married daughter, who is unable to give any monetary help. Total income £20 from investments. Friends gave £25. Board residence amounts to 25s. a week. Voted £26 in twelve monthly instalments.

Daughter, aged 71, of M.D. who died in 1859. Applicant asks for assistance as her sister, who was a grantee of the Fund, died at Christmas. Applicant received from friends £52 and she made £14 by plain sewing. Voted £5.

Widow, aged 68, of L.R.C.P. and S.E. who died last month after some years of illness. Her late husband was in receipt of an annuity from the Fund of £40, and he also had the old age pension. An adopted daughter lives at home and contributes £1 a week out of her earnings of 30s. a week. Applicant has no income whatever apart from the daughter's money. Voted £26 in twelve monthly instalments.

Daughter, aged 65, of M.D. who died in 1882. During the war she lived on her capital; this has all been realized and a large amount was lost in Germany; she is now destitute, and she and her friend have been living on the sale of furniture belonging to the friend. Brought to the notice of the Fund by the local branch of the Charity Organization Society. Voted £50 in twelve monthly instalments.

Subscriptions may be sent to the Honorary Treasurer, Sir Charters Symonds, K.B.E., at 11, Chandos Street, Cavendish Square, London, W.1.

The Royal Medical Benevolent Fund Guild still receives many applications for clothing, especially for coats and skirts for ladies and girls holding secretarial posts, and suits for working boys. The Guild appeals for second-hand clothes and household articles. The gifts should be sent to the Secretary of the Guild, 58, Great Marlborough Street, W.1.

Nova et Vetera.

THE LONDON COLLEGE OF MEDICINE.

THIS almost entirely forgotten venture of the proprietor and first Editor of the *Lancet* has been recalled to our memory by an interesting communication which we have lately received from Australia. Dr. Alfred Lendon of Adelaide has sent us a copy of a document which purports to confer upon Charles George Everard all the "privileges and immunities which may be conferred upon the Fellows of the London College of Medicine" in the future. This document bears the signatures of nine medical practitioners, including the secretary. All of them were in general practice except John Epps, M.D., and Thomas Wakley. Dr. Epps was a well known homoeopathic practitioner, phrenologist, and reformer, and although he was the friend of Mazzini, Kossuth, Miall, and Stansfeld, he had a much greater reputation among the masses than in the medical profession. Of the remaining signatories only one is known to fame. This was George Alfred Walker of Drury Lane and St. James's Place, whose public-spirited and successful efforts to reform the graveyards of London earned for him the sobriquet of "Graveyard Walker." He was also a pioneer in hydropathy, for he established steam baths at the back of his West End house.

The London College of Medicine was one of the results of Wakley's ill treatment by the authorities of the Royal College of Surgeons. Smarting under the moral and physical insults from which he had suffered when he was so forcibly ejected from the premises of the college in March, 1831, he determined to establish a rival institution, and a little more than a week after his expulsion a meeting of practitioners was held at the Crown and Anchor Tavern in the Strand, under the presidency of Joseph Hume, M.P., himself a medical man.

It was thereupon decided to form the London College of Medicine at once, in the hopes of obtaining an Act of Parliament or a Charter later. Only one discordant note was heard. Mr. Sleigh moved an amendment in favour of the revival of a scheme of his own. He claimed to have proposed the foundation of a British College of Surgeons and to have actually started it in 1829, but the meeting was against him, and to judge from a contemporary report in the *Lancet* (probably not, in this instance, an impartial witness), he was no match in dialectic for Wakley, who said that he had proposed the foundation of that college in 1824.

A committee was formed which speedily drew up rules and regulations and a constitution—as Sir Squire Sprigge says in his *Life and Times of Thomas Wakley*, "where the ruling body was to be elected by universal suffrage, where there were to be no grades of rank, or distinctions in title; where no monopoly in the teaching or the granting of certificates to the taught was to be countenanced, where the fees were to be low and only the standard of courtesy between examiners and examined high." It was to have a senate of thirty-six fellows, a chancellor, vice-chancellor, and scrutators. Seven members of the senate were to form a medical jury who were to examine candidates in public and award or withhold the diploma by a vote of the majority. Candidates for examination were not to be required to produce any certificates whatever. The fee for the examination was fixed at three guineas for practitioners and five for students.

An editorial article in the *Lancet* gave the scheme of government of the college in full, some of the sections of which betrayed the bitterness and exasperation with which Wakley regarded the authorities of the Royal College of Surgeons. Section 4 ran as follows:

"During the first year the Diploma from any University or College of Physicians or Surgeons shall be deemed a sufficient qualification, etc. . . . But the Diplomas of the London College of Surgeons, dated *subsequently* to Tuesday the 8th of March, the day on which the infamous assault was committed 'on the Members, will not be received.' (The italics are in the original.)

Section 10 shows that modesty did not characterize the aims and aspirations of the new college. It claimed the right of the president, council, and fellows to elect the

medical officers of the "great chartered hospitals." and to remove them for misconduct or incompetence. Naturally the new college was well advertised in the pages of the *Lancet*, and there are many glowing notices of its progress and many letters from sympathizers and would-be fellows in the volumes 1830-31 and 1831-32. In the contemporary volumes of the *London Medical Gazette* it is referred to in editorials and letters in a contemptuous tone, as "Collegium Wakleyanum." In the *Lancet* for June 13th, 1831, the following announcement appeared:

"The Committee of the London College of Medicine have engaged Offices at No. 9, Lancaster Place, Strand, that is, in that fine broad street which leads from the Strand to that magnificent structure Waterloo Bridge."

A month later it was announced that the offices were open and that the college was ready to examine candidates, etc., and it was confidently predicted that "the London College of Medicine will rise into a dignity and importance never before attained by any medical institution in the world." These are "prave 'ords," but alas for Wakley's high hopes! In the indexes of the volumes of the *Lancet* for 1832-33 not a single reference to the College of Medicine is to be found. It died of inanition, but not before it had granted some diplomas, as witness that of which Dr. Lendon has told us, and as this is dated in July, 1835, the college must have lingered on for some years. Wakley probably lost interest in it when he saw that it was not likely to supersede the old-established licensing bodies, and he transferred his energies to the more hopeful sphere of parliamentary action.

LIVERPOOL MEDICAL INSTITUTION.

TRIBUTE TO MR. F. T. PAUL.

At the conclusion of the clinical meeting of the Liverpool Medical Institution on March 11th the members assembled in the lecture theatre to witness a ceremony unique in the annals of this Liverpool medical society, and probably also in the annals of medical societies in general—namely, the presentation to the Institution of a bronze cast of the right hand of Mr. F. T. Paul, the distinguished surgeon. Mr. Paul was present, and received a generous welcome from many old friends. The President, Dr. J. C. M. GIVEN, was in the chair.

MR. FRANK JEANS, in the course of an eloquent speech, said that the name of Paul was known now to every surgeon in the civilized world, and would be mentioned in surgical history 200 years hence—not only because he invented Paul's tube, but also because he was responsible for much of the progress that surgery had made in the past. Liverpool should be pleased on reflecting that two epoch-making instruments—Paul's tube and Thomas's splint—emanated from that city; they would live because they were invented for a purpose, which purpose was founded on basic ideas of correct pathology. He thought that, as a remembrance of a past president of the Institution, and one of the most gifted operators who ever cast glory on a medical school, a cast of his hand would be acceptable, and the council at once agreed. Now, in surgery, hands were not everything, although they must, of course, be able to carry out the dictates of the surgeon's brain. When the Chirurgical Club visited Liverpool in 1911 Moynihan was never tired of praising Paul's dexterity and his light hand. Paul, further, had the ideal surgical temperament; no one ever saw him excited, least of all in an operating theatre. Mr. Jeans said he had an additional personal reason for wishing to pay a tribute to Paul, because it was to him that he owed the continued existence upon this earth of his wife. This hand had been

done in bronze from a plaster cast by H. Tyson Smith, the sculptor. It was a remarkable hand, the hand of a man who had worked. It was very like the hand of a 'cellist or a violinist because it was short and broad. 'Cellists and violinists had broad hands and not the long tapering fingers described in novels and the more expensive magazines. When Joshua Reynolds painted Mrs. Siddons he signed his name on the border of her gown and said, "I shall go down to posterity, Sarah, on the hem of your garment." He himself saw an easy way of going down to posterity by presenting this bronze hand, and he asked the President to accept it on behalf of the Medical Institution as a remembrance of a man whom all thinking surgeons regarded as one of the choice and master spirits of this age.

The President then called on Mr. PAUL, who welcomed the opportunity to acknowledge the courtesy of the Institution in accepting this gift, and the kindness of Mr. Jeans in thinking of it. He admitted that at first he had regarded this relic somewhat as a joke, as he had never taken his hands seriously. He recalled how on one occasion, when Professor T. R. Glynn asked him to see a case in consultation, he was obliged to apologize for the condition of his hands, stained as they were with microscopical and pathological reagents. Glynn had replied that he hated a man with clean hands, as they suggested he never did any work. Mr. Paul confessed that he had always been fond of using his hands from his earliest years; he regarded such use as the only way of training them in delicacy; at the same time, it must be remembered that a gentle touch came from the heart rather than from the hands—a touch inspired by a true sympathy with the patient's tissue; in this way only could a man attain the hand of a surgeon.

Dr. GIVEN then expressed his pleasure in accepting the bronze cast in the name of the Liverpool Medical Institution, and congratulated Mr. Jeans on having the fertile brain which could think of such a thing. Mr. Paul's hand had played an important part in the progress of pathology and surgery, and had also been used in the successful prosecution of many other arts. He was one of the founders of the Liverpool Medical School and a maker of its early reputation. He (the President) had known that hand for forty years. It had written his name in the medical school register when he first presented himself as a young medical student. It was a hand he had flown to in all surgical emergencies. Mr. Paul was a surgeon on whom the general practitioner had always relied; he had been depended upon always to say what was sound and best to the patient and his friends, and to operate in the best interests of the patient. He desired to thank Mr. Jeans most sincerely for his very acceptable gift.

Scotland.

TREATMENT OF SCOTTISH CRIPPLES.

A CONFERENCE was held in the City Chambers, Edinburgh, on March 16th, for the purpose of discussing a Scottish scheme with regard to the treatment of cripples. The conference was attended by delegates from various organizations interested in the movement, and the chair was occupied by Lord Provost Sir William Sleigh. The chairman said that while they might alleviate pain and help to brighten the lives of cripples by means of cripple aid societies, such measures were too late to effect cures, and it was necessary that something should be done in the early years of childhood. It was tragic to think, he said, that 75 per cent. of the cripples in this country might have grown up strong men and women, capable of earning their own living, if they had been treated at an earlier stage. In England there was a national scheme for the welfare of crippled children, and in Scotland there was need of a single scheme to link up clinics throughout the various districts. The present movement had the intention of taking up this matter. The Rev. Dr. T. Ratcliffe Barnett quoted an address by Sir Robert Jones, in which it had been stated that 80 or 90 per cent. of crippled children might have been turned into valuable industrial assets, instead of remaining the pathetic figures which many of them were, if only their cases had been taken in hand sufficiently early. The ideal means of effecting this was

to have a national scheme with central hospitals and outlying clinics, but this might take a long time to work out. Meantime, an essential beginning was to provide a central open-air hospital in the country, affiliated to a great teaching school like that of Edinburgh, which would become an orthopaedic centre for a group of several counties. Scotland must work out her own scheme under her own expert surgeons and doctors, with the help of her own business men. There were various reasons why this could not be accomplished with the premises and skill available at present. One was that no beds were available for such a purpose, for orthopaedic cripple cures could only be accomplished in special hospitals where patients could be kept and treated without any time limit, and where they could live continually in open air and sunlight, and be given regular education by approved teachers. Three great essentials of this work were preventive work, operative work, and after-care. The financial question must be solved by the general public on behalf of the hospitals, and the Edinburgh Rotary Club had been persuaded to take steps for raising funds and stimulating interest in the movement. An initial local scheme should not be impossible, and the further national scheme should never be lost sight of. Sir Harold Stiles, speaking of the scheme in detail, said its success would depend mainly upon the central hospital, which must be closely affiliated with the great teaching hospitals. The work must form part of the medical student's education so that they might get men educated to start the country hospitals in rural areas. Now that the Royal Infirmary of Edinburgh had acquired George Watson's College, he saw no reason why there should not be an orthopaedic department attached to that Infirmary. He hoped that the central hospital for cripples would be a new building situated in the Royal Infirmary, which would have at its disposal all the resources of the latter. On the motion of the Lord Provost, a committee representing various medical and philanthropic institutions was appointed to organize the scheme.

EDINBURGH WOMEN'S HOSPITAL.

The annual meeting of the Elsie Inglis Memorial Maternity Hospital, Edinburgh, was held on March 18th. Dr. Isabella Venters presided. The annual report showed that the ordinary expenditure for the past year had amounted to £9,316, and the income to £8,311, making a deficit of £1,005. A gift of £2,000 had been received towards the cost of building a garage and the purchase of motor ambulances, and as this fund now amounted to £2,560 the garage and ambulance would be furnished as soon as a suitable site could be found. With regard to Bruntsfield Hospital, it was stated that the number of patients treated had been 60 greater than in the previous year, and that the cost per occupied bed had been £150 3s. 5d. The committee appealed for funds, which it considered urgently necessary, to provide one or two extra wards in order to relieve the pressure on the gynaecological beds. Further gifts of £1,000 received from the Edinburgh Women's Emergency Corps on disbandment, and of £1,000 raised by lady golfers by means of competitions, were intimated, and it was decided that beds would be endowed and named after the bodies which presented them.

NEW GLASGOW LECTURESHIP IN GYNAECOLOGY.

The annual meeting of the Royal Samaritan Hospital for Women, Glasgow, was held on March 15th in the Merchants' House, Glasgow. Lord Provost Sir Matthew W. Montgomery presided, and commented upon the happy financial position of the hospital. Intimation was made that a donation of £6,000 from an anonymous friend had been received, of which the governors had utilized £5,000 to establish a university lectureship in gynaecology, to be known as the Royal Samaritan Lectureship. The balance was added to general capital. It was further stated that during 1925 the number of in-patients under treatment in the hospital had been 1,839, while 3,357 had consulted as out-patients. The ordinary income of the hospital during the year had been £14,215 and the expenditure £11,503, leaving a credit balance of £2,712. In moving the re-election of the officials, Sir Donald MacAlister, Bt., Principal of Glasgow University, thanked the donor of the Royal Samaritan Lectureship in the name of the University.

GLASGOW CHILDREN'S HOSPITAL.

At the forty-third annual meeting of the governors of the Royal Hospital for Sick Children at Yorkhill, Glasgow, on March 8th, Lord Provost Sir Matthew W. Montgomery congratulated the directors on the successful result of their appeal for funds to extend the hospital in order to meet the increasing demands on its resources. He said it was unique in the history of philanthropic institutions in Glasgow that an appeal for £75,000 should have been realized in less than six months by the simple process of collection. Through the generosity of the trustees of the late Mr. Peter Coats, accommodation at the country branch of the hospital at Drumchapel was to be doubled. This, together with the extension of the hospital at Yorkhill, would enable the institution to cope with a much larger number of cases than in the past.

MEASLES OUTBREAK IN GLASGOW.

During the month of February 5,986 cases of measles occurred in Glasgow, as against 60 in the corresponding month of 1925. The distribution of the outbreak has been fairly general over the city and the cases have been mild in type. Scarlet fever was also on a higher average than in the corresponding month of last year, 301 cases having been notified, as against 296 in February, 1925. There were also 218 cases of diphtheria, as against 151 in February, 1925.

DUNDEE ROYAL INFIRMARY.

A meeting of the governors of Dundee Royal Infirmary was held on March 8th, when Mr. D. A. Anderson, who presided, said that the expenditure for the past year had been £39,602, an increase of £3,335 on that for the previous year. The ordinary income, however, had reached a record figure, amounting to £36,051, which was an increase of £6,054, or 20 per cent. more than the income of the preceding year. The efforts of last year had shown that a considerable increase in income could be obtained. It was also intimated that accommodation was urgently required for the maternity department, and that a scheme to provide this was estimated to cost £30,000, which would have to be provided otherwise than by the reserve fund of the Infirmary.

MEMORIAL TO ABERDEEN PHYSICIAN.

The honorary staff of the Aberdeen Royal Infirmary has placed on the wall of the central hall of the institution an oak tablet in memory of Dr. Arthur Hugh Lister, and as a permanent record of the great services rendered by him to the city of Aberdeen and surrounding districts during his term of office as assistant physician and later as physician to the Infirmary. Dr. Lister died on active service in July, 1916; he held the rank of lieutenant-colonel and had received the C.M.G. in the previous June.

NEW FEEDING HABITS AND DISEASE.

An address was delivered by Dr. D. Chalmers Watson to the Edinburgh Women Citizens' Association on March 18th on present-day feeding habits. The lecturer referred to the remarkable change which had taken place in the diet of the country during the past fifty years. Two of the most outstanding changes were the enormous increase in the consumption of meat and the great increase in the consumption of sugar. Coincidentally with this there had been a great diminution in the use of oatmeal and an alteration in the quality of bread, of which the nutritive value had been greatly diminished by modern methods of milling. There had also been an enormous increase in the consumption of preserved food, which in most instances impaired its nutritive value. The lecturer believed that the prevalent conditions of adenoids, dental caries, pyorrhoæa, appendicitis and other acute abdominal conditions were in the main dependent upon the altered feeding conditions. He also attributed to a very large extent some chronic diseases, such as kidney disease, high blood pressure, and some diseases of the nervous system, to the same defects, and to deficient drinking of water. After the age of 40, the amount of meat foods should be materially restricted and a full supply of water should be drunk. In early years he thought that feeding should include hard foods and the avoidance of too much sloppy food, which

prevented the acquirement of the habit of mastication. The present-day system of relying mostly on preserved foods was a national danger, owing to the exclusion of vitamins. In this respect the influence of sunshine on food was revealed in the better quality of the wheat and barley associated with a season of sunshine which led to a greater supply of vitamins in the grain. There was also, he thought, need for much greater consumption of milk as a national food, and the amount of milk taken per head in this country was far short of what obtained in some other countries, especially America and Denmark. Only the higher grades of milk, which were now provided by recent legislation, should be used for drinking purposes.

DETERIORATION OF OPIUM.

At a meeting of the Pharmaceutical Society of Great Britain, held in Edinburgh on March 17th, Mr. D. P. Dott, Ph.C., F.R.S.E., contributed laboratory notes on the alleged deterioration of Indian opium on keeping. He referred to statements that Indian opium on keeping lost a considerable percentage of morphine. The result of periodic analyses which he had conducted of a sample of opium kept for two years was that the sample had shown no appreciable loss of morphine. With regard to the preservation of morphine hydrochloride in solution, for which the *Pharmacopœia* prescribes alcohol as a preservative, Mr. Dott stated that he had found acetic acid to give good results and to be much more economical.

Ireland.

MEDICAL REGISTRATION (IRISH FREE STATE).

In a recent issue the *Irish Times* published the following proposals, which it states were submitted on behalf of the Irish profession to the Free State executive as an acceptable settlement of medical registration in the Irish Free State.

In order to give effect to the wishes of the Saorstát Government to control the registration and the discipline of medical practitioners in the Saorstát, and at the same time to preserve the educational advantages and the world-wide status given by the partnership in the General Medical Council, the following procedure is suggested:

1.—Renew the partnership in the General Medical Council until such time as either the Government of the Saorstát or of England may apply for a termination of such partnership.

2.—(a) The Government of the Saorstát to set up a Medical Register for the Saorstát, and a Medical Council to supervise and control such Register.

(b) Direct the Saorstát Medical Council that any person of good repute who holds a medical degree or qualification from a university or college, etc., which is recognized by the Saorstát Medical Council, shall be eligible for entry upon the Saorstát Medical Register.

(c) Direct the Saorstát Medical Council that, in addition to the universities and colleges, etc., which may be recognized by the Saorstát Medical Council, any university or school, etc., which may be recognized from time to time by the General Medical Council, shall be recognized by the Saorstát Medical Council.

(d) Pass a law that any citizen of the Saorstát who may wish to practise in the Saorstát must have his name upon the Saorstát Medical Register.

(e) Pass a law that any person who is not a citizen of the Saorstát shall be debarred from practising in the Saorstát unless his name is upon the Saorstát Medical Register or upon some section of the General Medical Register.

The *Irish Times*, in its issue of March 17th, published a document purporting to give the text of proposals submitted to a subcommittee of medical men last December by Mr. R. C. B. Maunsell, President of the Royal College of Surgeons in Ireland, with a view to a settlement of the controversy. Mr. Maunsell has written a letter to the *Irish Times*, in the course of which he says of this document that, though it contains a lot of truth, whoever wrote it has been misinformed. The proposals as published are a verbatim copy of the original rough notes of proposals which were brought by him (Mr. Maunsell) before the subcommittee of medical men. "These proposals," Mr. Maunsell adds, "were considerably modified by us before they were laid before the Government, so that the document published is not the actual document which is under consideration."

SANITARY CONDITION OF MONAGHAN.

Dr. R. P. McDonnell, medical inspector under the Department of Local Government and Public Health, in the course of a report which was read at the last meeting of the Monaghan Urban Council on the state of the town, said that its sanitary condition was very unsatisfactory. Wretched hovels, inhabited by human beings, without light, without space, and without the ordinary conveniences of a dwelling-house, went to make up the lanes and side streets of the town. In the interests of public health and public decency these dens should be abolished and proper houses built. The byres where the milk consumed in the town was produced were on a par with the slum houses—dark, damp, and dirty. Healthy, clean milk could not be produced in some of the cowsheds visited by him. He called attention to the fact that houses condemned as unfit for human habitation were still occupied, and the sanitary authority was unable to provide suitable houses, as there was not a proper sewerage system. Dealing with the dairies in the town, Dr. McDonnell said that the condition of some of the byres was deplorable. He visited three dairy yards, in two of which the production of clean milk would be impossible. One was particularly bad, the byre being dark, unventilated, and filthy. "I cannot understand," he observed, "any sanitary authority allowing milk to be produced amid such surroundings. I have never seen milk produced under such filthy conditions as those I inspected in Monaghan." Proceeding, he said there was no inspection of the meat and milk supplies carried out in the district. The surroundings of the slaughterhouses in the town were decidedly insanitary. He recommended a municipal slaughterhouse, with a charge for its use, and arrangements for disposal of the blood and offal to some fertilizing manufacturing company, instead of allowing it to run into the sewers. The sewerage arrangements were very bad—only old stone drains; many streets had no sewers. The town might be said to be without any provision for the disposal of domestic sewage. The old sewers were worse than useless, and constituted a grave menace to the public health of the town by reason of their inadequacy to deal with the volume of sewage requiring removal, and the dangers and gross pollution caused by their discharge into an open river which ran close to the town. About a hundred yards of one of the main streets of the town was without any sewerage, several other streets being unprovided for in this respect. Some two hundred dwelling-houses were without sanitary conveniences of any kind. Dr. McDonnell described the lanes and alleys as in an appalling condition. He visited one of the common lodging-houses; it was without any sanitary convenience, the rooms were unclean and untidy, the beds unmade, the windows shut, and the ordinary sleeping room conveniences filthy in the extreme. This house should not be registered until proper sanitary accommodation was provided and until proper arrangements were made for the separation of the sexes.

England and Wales.

JOINT TUBERCULOSIS COUNCIL.

THE Joint Tuberculosis Council originated from the co-operation of the Tuberculosis Group of the Society of Medical Officers of Health, the Tuberculosis Society, and the Society of Medical Superintendents of Tuberculosis Institutions. Its first meeting was held in March, 1924, and a report of its activities until December 31st, 1925, has recently been received. Besides assisting the Ministry of Health in the preparation of its memorandum 37/T, dealing with statistical reports, to which we referred on September 26th, 1925 (p. 581), the council has instituted collective research into certain aspects of tuberculosis. The subjects selected were the incidence of non-pulmonary tuberculosis among the contacts of pulmonary cases, the frequency of marital infection, the obtaining of employment for male patients after sanatorium treatment, the influence of marriage, pregnancy, and parturition on tuberculosis, and the fate of young children in tuberculous households. A post-graduate course was organized in 1924, and two

courses in 1925; we referred on March 20th (p. 540) to the projected arrangements for 1926. The problem of the employment of tuberculous persons has been studied systematically and a formal report is in course of preparation. Evidence was given on behalf of the council by Sir Henry Gauvain and Dr. Lissant Cox before the Royal Commission on National Health Insurance, their chief recommendations being the following: The period of sickness benefit should be capable of extension in the case of tuberculous patients, and it should be possible to arrange for diminished sickness benefit during part-time employment; dentistry should be included, special consideration given to deposit contributors, and surpluses be available for financial aid, research work, and after-care. The council is now composed of representatives from various tuberculosis societies, representatives of Government departments interested in tuberculosis problems, and delegates from hospitals, medical schools, and universities. The British Medical Association is represented by Dr. G. B. Hillman and Dr. Arnold Lyndon.

KING EDWARD VII SANATORIUM, MIDHURST.

The annual report of the King Edward VII Sanatorium for the year ending June 30th, 1925, shows that the sanatorium received nearly half of its patients from London and the neighbouring counties. It is suggested that the sanatorium is not sufficiently utilized by members of the professional classes, for whom it was originally intended. The medical superintendent, Dr. R. R. Trail, states that during the year under review 266 patients were admitted and 213 were discharged. Of 203 cases in which the diagnosis of pulmonary tuberculosis was established, 139 were either "moderately advanced" or "advanced," and only 64 were considered to be "early." Of these 203 cases, however, 127 patients were subsequently found to have reached the stage of arrested disease, or to have shown considerable improvement as the result of treatment. It is pointed out that very few patients can afford to prolong their stay beyond four or five months. Artificial pneumothorax was performed in twelve cases. The x-ray department has been almost completely reorganized; protective measures have been adopted to bring all the apparatus up to the standard of the National Physical Laboratory, and the provision of two exhaust fans and the installation of coronaless leads and terminals have tended to lessen the fatigue of the operator. Each patient is examined radiologically within a week of admission to the sanatorium. Research has been carried on in the pathological laboratory to determine the value of the treatment of tuberculous laboratory animals by esters and salts of certain unsaturated fatty acids, including ethyl hydnocarpate.

CORONERS' INQUESTS IN LONDON.

From returns reported by the London coroners to the London County Council it appears that the number of deaths brought to the notice of the coroners in 1925 was 6,758, and an inquest was deemed necessary in 73 per cent. Of the inquests, 87 per cent. necessitated *post-mortem* examinations, and in 104 cases an independent necropsy by a special pathologist was required. A verdict of murder was returned in 29 cases, an increase of 9 over the previous year, 8 verdicts of manslaughter were recorded, and the total number of suicides was 515, an increase of 26. Thirteen deaths occurred from want and exposure; in 17 inquests the verdicts attributed the cause of death to excessive drinking, most of the cases being due to the increasing habit of drinking methylated spirit; deaths from want of attention at birth decreased to 36 from 48 in the previous year; 1,761 persons met their death by accident. A verdict of "death from natural causes" was returned in 2,438 cases, and "cause of death unknown" in 14. Inquests on newly born children numbered 113; there were 5 verdicts of murder of the newly born, and in 55 cases it was decided that the child was stillborn. The cost to the Council of the inquests held in 1925 was £25,335, a reduction in expenditure due chiefly to the abolition of the fees formerly paid to Poor Law medical officers, which accounted for an expenditure averaging about £1,500 a year. The fees paid to special pathologists amounted to £341, and to toxicologists £92.

ANTIVENEREAL MEASURES IN LONDON.

The London County Council is continuing for its next financial year the existing arrangements under the Public Health (Venereal Diseases) Regulations, 1916. The total expenditure for London and for certain adjoining county authorities which participate in the hospital and laboratory facilities available in London is estimated for the coming year at £123,785 (the share of London proper being about 82 per cent.), as compared with £123,205 for the current year. Besides this sum, which is for hospital and hostel facilities, £2,000 is voted for the supply of salvarsan or its substitutes, and £2,000 for publicity and propaganda work. The number of days of treatment of in-patients at the various hospitals in 1925 was 29,313 in the case of male patients, and 73,141 in the case of female, as compared with 31,620 and 70,836 respectively in the previous year. The total number of new cases coming to the clinics in 1925 was 26,182, a slight increase, but of these the unusually large number of 8,680 were found to be not infected, with the result that the number of new venereal cases (17,502) is the lowest figure for the last five years. Of this total number of new cases, those of syphilis accounted for 5,902, those of gonorrhoea for 11,321, and those of soft chancre for 279. It is pointed out by the London County Council that these figures are not the full extent to which venereal diseases come under treatment in London, as a not inconsiderable number of cases receive treatment by general practitioners. The number of attendances at the clinics (646,131) was the highest during the last five years, the figure for the previous year being 589,002, and the number of pathological examinations made for practitioners at hospitals (26,346) again showed an increase.

India.

MEDICAL TREATMENT AND EDUCATION IN THE PUNJAB.

It is satisfactory to be able to record that in the Punjab during 1924 the number of hospitals and dispensaries increased from 626 to 640. At the close of the year there were thirty-one mobile dispensaries, which are greatly appreciated in districts where facilities for medical relief are scanty; they have proved particularly valuable in epidemics. The Government is considering a scheme to provide one dispensary for every 100 square miles or 30,000 of population. At present the average area served by each hospital or dispensary is 147 square miles; in some districts, therefore, patients have to travel very long distances before they are able to reach any institution for treatment. The total number of patients of all classes treated during the year was 5,935,000, of which 109,506 were in-patients. Malaria and cholera considerably increased during the year. In the prefatory note to the *Annual Statements of the Dispensaries and Charitable Institutions of the Punjab* for the year 1924 special attention is paid to maternity welfare and the training of women. On October 25th, 1924 (p. 786), we mentioned the opening of the Lady Reading Hospital for Women and Children at Simla in the previous spring, and referred to the large number of patients who were already receiving treatment. Up to December 31st this number was 6,330, and the provision of this up-to-date hospital was undoubtedly the most notable feature of the year. The Lahore Maternity Hospital, which was opened in February, 1924, with a view to training in midwifery students of the King Edward Medical College, has dealt with 627 patients up to the end of the year, the students performing a considerable amount of the practical work. It is hoped that the proposed new maternity hospital will be completed by 1927. Good progress is reported from the Punjab Medical School for Women at Ludhiana. On February 21st, 1925 (p. 382), we mentioned the opening of the new maternity block; the number of new admissions of students has nearly doubled as compared with the previous year, indicating that the institution is gaining popularity and that the possibility of a medical career for women is being increasingly realized. Research in Indian drugs is proceeding at the King Edward Medical College, Lahore.

HOSPITALS IN BURMA.

During the year ending December, 1924, the number of hospitals and dispensaries in Burma increased from 284 to 289, and the total number of patients treated at institutions other than those belonging to the military police and the railway was 1,990,972, as compared with 1,942,775 in 1923. There was a slight decrease in the patients treated in military police hospitals owing to the closing of a number of outposts, but the work of the railway hospitals increased, and one new dispensary was opened. The most prevalent diseases were malaria, disorders of the digestive system, skin troubles, and diseases of the respiratory system. Malaria is prevalent in most parts of Burma, and reclamation works have been undertaken in various places. Under the supervision of the military police stagnant pools are being drained and filled up, rank vegetation cleared away, and kerosene oil applied to collections of water where removal is not possible. The number of cholera patients was more than double that in the previous year, but the death-rate fell from 51 per cent. in 1923 to 36 per cent. in 1924. A slight fall occurred in the number of plague cases, and the rate of mortality was also slightly less. Tuberculosis increased, and goitre remains prevalent in many parts of the country. It is proposed to start a venereal clinic at Rangoon as soon as the additions now being made to the General Hospital building are completed. It is expected that during 1926 a commission on venereal diseases will visit Burma, and also that a special inquiry into beri-beri will be held. The General Hospital at Rangoon accommodates at present 515 adults and 20 children. The number of in-patients in 1924 was 11,075, as compared with 10,363 in the previous year. During the next few months a home for incurables will be built to accommodate a hundred cases, and some of the congestion in the hospital will be relieved. It is hoped also to have a gynaecological department in connexion with the new Dufferin Hospital, with accommodation for nearly a hundred cases. Still more hospital accommodation is, however, urgently required in Rangoon. A diabetic clinic was started at the General Hospital in June, 1924. Post-graduate courses are held twice yearly.

KING EDWARD VII. MEMORIAL HOSPITAL, BOMBAY.

The King Edward VII Memorial Hospital, Bombay, was opened on January 22nd by the Governor, Sir Leslie Wilson, thus completing the scheme for the extension of medical relief which was undertaken by the municipality in 1907. Nearly six years has been required for its building, and adjoining it is the Medical College, equally well equipped. Both hospital and college have been designed by Mr. George Wittet, with the co-operation of Mr. Pite, designer of King's College, London. The new hospital is based upon the pavilion principle, and will accommodate 304 beds normally, with ample provision for expansion to 400 without overcrowding. Mr. Joseph Baptista, president of the Bombay Municipal Corporation, in his speech of welcome to the Governor, expressed the hope that a tropical school for medicine would now be created, either by the help of the Government or by private generosity, and that such a school might bear the name of Queen Alexandra. The Governor, in his reply, congratulated the municipality on the valuable teaching facilities provided by the Medical College. He was glad that a policy of an honorary staff for the hospital had been adopted. In the course of the proceedings it was announced that endowments for seven scholarships had been received, a sum of money given to supply annually warm clothing to the hospital patients, and also a set of sixty bound volumes of the *BRITISH MEDICAL JOURNAL* in a cabinet.

VACCINATION IN INDIA.

Annual reports for 1924-25 which have been recently received from various parts of India indicate a gratifying spread of knowledge among the people with regard to the prevention of small-pox. In Madras the number of vaccinations and revaccinations was 2,033,997, as compared with 1,912,565 in the previous year; while in the Central Provinces and Berar 521,116 were recorded—a corresponding increase of 19,718. This improvement is directly attributed to the activities of the district health staffs in supervising the work of vaccinators, the detection of unprotected

children, and to extensive and persistent propaganda. In areas where a local decrease occurred the absence of these factors was obvious. The reported decline in the number of vaccinations in the Punjab during the year under review is attributed in part to a fall in the birth rate and in part to the administrative disorganization due to the plague epidemic, but since further efforts have been made to increase the efficiency and thoroughness of the vaccination work a decided improvement is probable during the present year, especially as vaccination is nowhere unpopular, except perhaps in the Simla hill states, and as a rule apathy, rather than hostility, is the enemy. The small-pox death rate during the last three years was highest in the three Punjab districts of Montgomery, Jehlum, and Shahpur, which were least protected against small-pox as determined by the proportion of successful vaccinations per 10,000 of the population during the preceding six years. In Hyderabad town, where only 26 per cent. of the children under 1 year of age were successfully vaccinated, the epidemic during the year under review resulted in 190 cases, with 120 deaths. Of the patients who died—omitting twenty-one whose vaccinal condition was unknown—ninety-eight deaths occurred amongst the unvaccinated. In the Bombay Presidency as a whole there was an increase in the number of secondary vaccinations and a decrease in the primary, as compared with the previous year. From Bihar and Orissa it is reported that there is a diminution in the opposition to vaccination, but a large proportion of the population is still unprotected, vaccination not being compulsory throughout the province. It is feared that there is serious risk of a severe epidemic during the present year.

Correspondence.

LEAD IN THE TREATMENT OF MALIGNANT DISEASE.

SIR,—The animus—and the value—of Dr. Leitch's criticism at the recent discussion upon the lead treatment of cancer before the Medical Society of London will be obvious to all if I place before you what Dr. Leitch ascribes to me and what I actually wrote.

According to Dr. Leitch, "Dr. Adami vouched for the fact that he had seen thirty previously incurable cases cured; he had also letters from another ten cases." (At this point I demurred that I had carefully refrained from speaking of these cases as "cures.") Dr. Leitch amended his remark by saying, "Well, they had no recurrences," and added, "But Professor Bell himself at that time claimed only thirty-one."

If we turn to what I actually wrote,¹ it was: "On the mornings of July 15th, 16th, and 17th, 1925, as a medical member of that executive I attended with others a review or survey of a number of old patients who had from the beginning been subjected to Professor Blair Bell's treatment. Of these I saw and took notes of thirty. Letters were read from ten others, all declaring themselves in good health, who, from one cause or another, could not respond to the call." And later I point out "the absence of evidence of 'recurrences' " in the thirty cases seen by me.

This was in July. I knew nothing then of the method of record Mr. Blair Bell would employ for his Toronto address in November, but only that I was surveying a number of patients who had been subjected to the treatment; and I stated succinctly what I saw. Now, while probably the majority of the cases seen by me come under Blair Bell's category of "believed cured," some of the cases may well have come among those, fourteen in number, which Blair Bell, in his statistical table, puts down as too recent for exact decision; some among the ten which he describes as "having the disease completely arrested"; some quite possibly in the other category of nine cases of "complete treatment refused, but patients living normal lives." These last three categories Dr. Leitch overlooks in order to force the point that I had testified (dishonestly, as he seems to imply) to being acquainted with forty cures, whereas Blair Bell himself only admitted to thirty-one cases "believed cured."

¹ *Lancet*, March 13th, 1926, p. 543.

I leave it to your readers to appraise Dr. Leitch's mode of criticism. If the figures that I have given have any meaning, surely it is that Mr. Blair Bell has been eminently conservative in his estimate of what may be regarded as "believed cured."—I am, etc.,

Liverpool, March 23rd.

J. GEORGE ADAMI.

** A comprehensive report of the debate to which Dr. Adami refers will be found at page 568.

DYSENTERY IN MESOPOTAMIA.

SIR,—I am indebted to your correspondent Dr. Jerwood for his contribution to this discussion. Controversy is always made easier if you can get your opponent to prove your case. Dr. Jerwood does this very succinctly for me in his letter (March 20th, p. 545), in which he professes to find nothing remarkable in the fact that in the recently published Report on the Health of the Army for 1923 the prevailing type of dysentery in Iraq is shown to be amoebic.

In stating that this is in accordance with the bacteriological findings at No. 133 British General Hospital, Kut, in 1918, where over 94 per cent. of the cases were of this nature, he admits that he is aware that this was quite contrary to the experience of all the other hospitals in Mesopotamia. That is precisely my case and why I find it difficult to believe the army report. At that time and in the periods immediately preceding and following it there is no doubt that the work of competent observers shows that the prevailing type of dysentery in Iraq was bacillary, and any isolated opinion to the contrary must be received with the same incredulity that attaches to the report in question. Local conditions peculiar to Kut could in no way be held responsible for a result so completely at variance with the general experience, and one which to me is so suggestive of faulty observation. The mere fact that any observer was able to demonstrate the presence of *E. histolytica* in over 94 per cent. of a series of 149 cases, granted that they were all amoebic and subjected to repeated examination if necessary, would be no less remarkable than failure to demonstrate *B. dysenteriae* in a single one.

The explanation put forward by Dr. Jerwood would be fanciful, even were it based upon the known facts relating to the spread of dysentery. The facts are, however, otherwise. There is no evidence to my knowledge that amoebic dysentery is pre-eminently a fly-borne disease in contradistinction to bacillary dysentery, essentially water-borne. Both types alike are spread by infected water and by fly contamination. Indeed, the alliterative mnemonic, "the filthy feet of faecal feeding flies," was used with reference to the spread of bacillary dysentery and occurs in that context in the *Mediterranean Medical Diseases Handbook* (p. 64).

With regard to the water supply in Mesopotamia during the period in question, this was probably quite as good as it is at present. In the large administrative areas it was generally centrally chlorinated. My weekly examination almost invariably showed no lactose fermenters in 10 c.c.m.—a very fair standard of purity in a tropical, uncivilized country.

There would appear to be a slight seasonal variation in the prevalence of the two types of dysentery, the amoebic incidence being slightly higher in the hot weather. A slightly higher percentage of amoebic cases also occurred amongst Indian troops. Neither of these factors, of course, has any bearing on the point in question.—I am, etc.,

MIGRAINE AND OTHER NEUROSES.

SIR,—Your reviewer, in his kindly notice of my little book (March 20th, p. 532), has, perhaps, overlooked one point which seems important.

The struggles towards success made by so many young and vigorous migrainous people are conscious and voluntary struggles; the "repression" of the "rage and humiliation" felt in moments of failure—or, rather, the expression of this rage and humiliation in the form of a migrainous paroxysm—and the subsequent or contemporaneous

utilization of the attack as an excuse or compensation, are "unconscious" processes until, during treatment, they are brought into consciousness. This, briefly, is my thesis. But that young and vigorous and ultimately successful men should suffer from migraine, so far from, as was said, "negating the idea" or thesis, is indeed one of the observational foundations of the idea or thesis. Another foundation in experience for the idea or thesis is that the migrainous, and the neuralgic, almost without exception, accept it as adequately explaining their own state—that is, they do so unless they impatiently reject it without attempting to understand it. As soon as they accept it they cease to suffer; so that, even if the thesis be considered invalid by the critics, action based upon it nevertheless affords a speedy and often permanent "cure."—I am, etc.,

London, W.I, March 19th.

F. G. CROOKSHANK.

MENTAL IRRITABILITY AND BREAKDOWN IN THE TROPICS.

SIR,—The Bishop of Singapore, in his letter published in the *JOURNAL* of March 13th (p. 503), raises a very important question, and one that can only be superficially touched on in a letter. The upset of mental balance he writes of, and the disastrous breakdown that may follow, are all too frequent in the experience of any medical man working in the tropics. He asks for some enlightenment as to the causation, and for some guidance in avoiding a condition that has wrecked many a useful and promising life.

In the course of a long practice among Europeans in the Far East I have had many cases of the milder loss of mental balance to deal with, while as one of the physicians to H.B.M. Consulate-General, and Supreme Court, in Shanghai, it fell to my lot to investigate most of the cases of mental breakdown occurring among British residents in that part of China, and I can fully endorse all the bishop says as to the frequency of suicide among valued members of the community during the hot season of the year. The essential mental changes that occur in the tropical weather are:

1. Partial loss of memory—a tropical amnesia—with mild confusion and interference in the sequence of thought.
2. Dullness.
3. Irritability, followed in severe cases by—
4. Marked depression, and even suicide.

The underlying cause is probably extraneous disturbance of the cortical circulation, associated with excessive irritability and rapid fatigue in the cortical cells.

The circulatory disturbance, seen in its most acute form in heat stroke, is dependent on five main factors:

1. The direct action of heat on the head and back.
2. The irritation of the visual cortex by exposure to the continuous glare of the sun. To this must be added the fatigue due to latent defects in the eyes, described by Mr. MacCallan.
3. The irritation and fatigue of the cortex generally, caused by the continual stream of afferent sensations of discomfort from all parts of the body.
4. The hyperaemia induced by alcohol, often taken to whip the brain to increased effort.
5. The failure to rest the brain sufficiently during the hot periods of the day.

An almost overpowering desire to sleep is experienced after the midday meal, and this desire should be satisfied. It is the cry of the fatigued and hyperaemic cortex for Nature's prime remedy. The sleep may not be a comfortable one, but it is usually heavy, and the harassed cortex is relieved. To hurry back after tiffin and finish the day's work in time for the afternoon game of tennis, golf, or cricket, without a rest, is to put a severe strain on the nervous system, and one that will soon make itself felt among the highly strung and congenitally nervous.

The native in Central China, with generations of experience behind him, affords an interesting example of how the heat should be borne. With the advent of summer the whole mode of life is changed. Clothing is reduced to a minimum, a fan is carried, diet cut down, work done in a leisurely manner, and a deep sleep indulged in at midday. In the late afternoon he brightens up again, and does not seek his bed until the cooler part of night is reached. He is largely protected by Nature against the direct effect of

heat upon the head and of glare upon the eyes, and he takes good care that his brain is not called to any undue effort.

As the bishop says, the degree of temperature is not the sole factor in determining the prevalence of nervous breakdown. A study of the medical reports of the missionary societies working in China shows a far higher percentage of disablement from this cause in North China, where the air is keen and dry, than in Central China, where humid, sultry conditions prevail. In the latter case there is no stinging in the air, the cutaneous and splanchnic vessels are not stimulated to contraction, and this may save the cerebral vessels from overcongestion.

The indications, then, are to guard carefully the cerebral circulation, and to save the cortex from overfatigue. The head must be protected with a good helmet and the eyes with good sun glasses. Alcohol must be avoided when the sun is up. The brain must be given a good rest in the middle day. Healthy circulation in muscles and limbs must be promoted by taking sharp and vigorous exercise for a short period in the late afternoon, but *not* on the top of a long and exhausting day spent without a rest. After exercise the warm bath, great care being taken to avoid any splanchnic chill. The healthy action of the skin and the splendid relaxation that follows the right form of exercise, and the bath, is the surest preventive of cerebral congestion and its evil effects.

I have only touched on the physical side of the question. Intellectual, aesthetic, and emotional influences also play a part, as the bishop will know from his long experience among all types of Europeans working under conditions so widely different from their natural environment.—I am, etc.,

W. B. BILLINGHURST.

London, W.I, March 20th.

SIR,—The Bishop of Singapore's letter is very interesting, and I shall be glad to make a few observations which may be of use.

The whole subject of living a healthy life in the tropics bristles with difficulties, of course. A man or woman exiled from home and relatives and friends, and planted among strange people whose way of living and mode of thinking are totally dissimilar to his own, must "worry" to some extent, even if this be more or less subconscious. When this place of exile happens to be the tropics the smallest exertion, to many people, becomes distasteful. These people, however, take food just as though they were using it up in physical exertion. They feel the need of its stimulating qualities, and in the circumstances get "tropical liver." To meet the bishop's letter we will leave alcohol out of the question. Just as we can regulate a stomach in great measure by what is put into it, so we ought also to send from this country to the tropics the type of individual who is likely to succeed there. These, I think, will be found to be the dark-haired, dark skin, brown eye type (roughly) in preference to the light-haired or blond type. In any case, all who contemplate a lengthy stay in the tropics should also be of the phlegmatic type, and be free from cardiac and digestive troubles. Any familial insanity strain should be a bar.

A good deal can be learnt from the natives of a particular locality, within limits, and duly interpreted and applied scientifically by the white man. The Chinese custom of wearing thin black clothing is very sound, as it assists the pigment in his skin to stop the ultra-violet rays of the sun penetrating his body and injuring his nervous system. His clothing absorbs heat rays, but these are counteracted to a great extent by the looseness and thinness of the clothes, and by the fact that he has to exert himself physically to earn a living, and so perspires, and in this way creates a draught of air round his body. This carries away the noxious vapours given off by the skin. The native is sparing in his diet, and has less bodily poisons to deal with. One of the fittest men I have ever known was a ship's captain who had sailed east for twenty-five years and whose dinner in the evening was more often than not an apple and a glass of water. He was also an abstainer from alcohol and a non-smoker.

There can be no doubt that the direct rays of the tropical sun are very enervating, as anyone knows who has experienced them. One has only to observe the Chinese as they step out from the shade of one shop verandah to another a few yards distant in, say, Hong-Kong. For that short distance in the sun up goes a wide arm sleeve over their heads. On a hot day one sees hundreds of them walking along thus protecting their craniums from the sun. It would be well for white people to imitate them in the use of loose-fitting black clothes, covering them with thin white material for official and social wear, and khaki when on shikar. This would keep the distinction of native and European, and would reflect heat rays and absorb ultra-violet rays. It is possible that a material could be made, white on the outside and black inside, to obviate outer and inner clothing. Next to the skin, of course, also I have found it advisable to wear a thin woollen vest.

The matters I have mentioned are all of great importance, but they do not go far enough. The bishop very rightly asks why these cases of nervous exhaustion, amounting in some cases to insanity, are found in some tropical places and not in others. I think the reason is to be found in the presence or absence of "winds." Winds playing on the surface of the body stimulate the cutaneous circulation, and so obviate any stagnation in the general circulation; they stimulate the cutaneous nerves, and so reflexly the central nervous system; they evaporate perspiration, and carry off body heat, so making existence less burdensome; and they carry off waste products given off by the skin in the form of gases; they also excite the lungs to deeper breathing, and these, therefore, give off more excrementitious matter than when sitting languidly in a close, still atmosphere. In Singapore, in a dead still atmosphere, one feels the need of a ricksha to go the shortest journey; whereas on a much hotter day, but with a gentle breeze blowing, I have walked from the river front at Nanking to the Gouleau Tower and back without discomfort.

If absence of "winds"—that is, comparative air stagnation—has a very great deal to do with these tropical nervous cases, as I firmly believe it has, what is the remedy? Obviously, the ideal method would be to have frequent trips to some place where one could enjoy a breeze; in the exigencies of the civil and military services, as also in commerce, this, of course, is rarely feasible. The only other way is by efficient forced ventilation indoors, the use of a fan wielded by oneself out of doors (again taking a cue from the natives), and a certain amount of physical exercise each day. I have been in many places where fans and punkhas were used, but rarely where the ventilation was scientifically correct. It is not sufficient to cause a "draught" by merely causing a movement of vitiated, heated air; the whole of the air requires to be moved from the room and continually replaced by fresh air from outside (cooled by passing through wet muslin frames). I have not tried coloured glasses in the tropics, but I know of people who have used them with great benefit.—I am, etc.,

ANDREW S. McNEIL, L.R.C.P.S. Ed.

Liverpool, March 20th.

SIR,—The Bishop of Singapore draws attention to a question of great importance to European residents in certain tropical countries. He is perfectly correct in stating that many Europeans tend to become "nervy" in time.

The condition frequently came under my notice during a service of twenty years in the Uganda Protectorate, and was responsible for many, if not most, of the cases of invaliding. I am aware that Dr. Forbes in Kenya considered that it was due to a hitherto undescribed malaria parasite, the accounting for certain regrettable incidents between natives and Europeans. I do not think, however, that anyone was able to confirm his observations. As regards Uganda at least, I found all my cases were associated with a greater or less degree of atonic dyspepsia and dilated stomach, which produced a neurasthenic condition. In fact, no one cause can be assigned: it is due to a series of factors all tending to impoverish the nervous system. There is the unavoidable monotony of life in

remote stations, often isolated and without any of the great amenities of life; this, aggravated by indifferent food, tough African chicken or goat, rendered almost unpalatable by the well meaning intentions of a native cook, unappetizingly served, and needing pungent sauces to give it a flavour, and eaten to the accompaniment of a book propped up at the side—is it any wonder that digestions are ruined and there is a lack of proper assimilation? Hence the nerves are starved. The circle is then a vicious one, as this lack of nerve tone impairs further the digestive powers, hypochlorhydria is often present, and thus the vicious circle is maintained. If, in addition, the patient suffers from malaria or other disease he rapidly presents a picture of a neurasthenic. The progress is insidious, and unless treated promptly the despondent mental condition induced makes him wish to throw up his job or even to commit suicide, while he lacks self-control, everything irritates, and the irascible temper induced easily accounts for such outbursts as one has seen. It was my practice to watch my patients carefully for early symptoms and to persuade them to take the proverbial stitch in time. Such cases are quite unsuitable for the lonely sanatorium, even if healthy. My own advice to such was to go to the capital, mix more with their fellow men, visit the theatres, etc. It is the mental change they need more than the physical. Of course, if home leave was due that was much the best. Wherever one has much dealing with irritating natives, whose mental outlook is really that of children, the risk of this condition occurring is much greater, and it is a wise Government that insists on frequent home leave for its officials, as they return with minds freshened and enthusiasm renewed. I have noticed that if a man takes up a hobby keenly, no matter what it is, he scarcely suffers from the monotonous isolation and conditions of his station. If he has a wife also he escapes, as his feeding is looked after better.

I am no doubt unorthodox in this respect, but I am convinced that the constant taking of quinine as a so-called prophylactic, especially taken, as it so often is, before food, under the conditions I have described, is responsible for part of the deterioration of digestive powers, and when the atonic neurasthenic state arrives quinine is not only scarcely absorbed, but acts as an irritant. Of course, excess of alcohol and irregular living are injurious, but they, in my experience, hold a very small position among causal factors, and I am at one with the bishop in this. The remedy, therefore, is to treat cases early, and not to keep unsuitable men long under isolated and trying conditions. Frequent home leave is a paying business proposition where the tropics are concerned.—I am, etc.,

Liberton, Edinburgh, March 17th. R. VAN SOMEREN,
Colonial Medical Service (ret.).

COMMON SENSE IN RELATION TO DOUBTFUL TUBERCULOSIS.

SIR,—The correspondence on this subject has brought out what is indeed well known to sanatorium superintendents and others—namely, that there are sometimes "social consequences" of sojourn in sanatoriums which may be "disastrous" to patients. An ex-sanatorium patient may be ostracized and even persecuted. This is nearly always unjustified. The knowledge that tuberculosis is partly due to an infective organism and the fact that it has become a notifiable "infectious" disease has done harm as well as good. Still too often is pulmonary tuberculosis classed in the public mind amongst such infectious diseases as small-pox, scarlet fever, etc.; and the profession does not always dispel the errors of the half-knowledge leading to this wrong grouping. When one finds that an ex-sanatorium patient who may have had but the slightest symptoms, and who for weeks or months before discharge has had no sputum, is treated as a leper by relatives and friends or by those from whom he seeks lodging, then it is high time that the half-knowledge should be turned into full acquaintance with the facts. Massive doses in unhygienic surroundings to susceptible individuals (who are generally either infants or adults from countries where the tubercle bacillus has not become implanted ubiquitously) are necessary conditions for the production of disease. It is the

ex-sanatorium patient who is generally the safe person to live with; for even if he is still an open case he knows the simple precautions which it is necessary to take in order to obviate entirely his being a danger to others. He is an apostle of hygienic living, too. He loves fresh air, due rest periods, and he eschews the catarrh-monger.

Surely if these things are realized the "benefit of the doubt" would be to do as Dr. Mackey originally suggested, and place the individual in a well conducted sanatorium, which, as Dr. Weatherhead has said, is one of the last places where one would be likely to pick up tubercle bacilli. If a full understanding of the elements in the causation of tuberculosis were realized, then, too, no doctor would suggest the necessity for specially isolated rooms for suspects in sanatoriums.—I am, etc.,

Mundesley, Norfolk, March 23rd.

S. VERE PEARSON.

TESTS FOR DRUNKENNESS.

SIR,—In the report of the discussion by the Marylebone Division of the British Medical Association, which appeared in the JOURNAL of March 6th (p. 434), medical practitioners will find much information which will be of service to them in examining men charged with alcoholic intoxication while driving motor vehicles, instances of which are now so frequent.

There is one point, however, with regard to this subject which deserves more attention than seems to have been given to it, and that is the striking effect which alcohol has in diminishing the sense of danger.

"Inspiring bold John Barleycorn,
What dangers thou canst make us scorn!
Wi' tippenny we fear nae evil;
Wi' usquabae we'll face the devil!"

So we read in the immortal *Tam*. This effect too, it must be borne in mind, is produced by a smaller amount than is required to bring about cerebral changes which can be recognized by any known tests.

What amount of alcohol is required to lessen caution in a dangerous degree it is impossible to say, but it may well be that a very small amount is sufficient at some critical juncture to turn the wavering balance of the judgement from the side of safety to that of danger—a danger which ends in disaster.

The only conclusion, therefore, which one can come to is that no one who has recently partaken of alcohol should be allowed to drive a motor vehicle.—I am, etc.,

Driffield, E. Yorks, March 8th.

JOHN R. KEITH.

A CLINIC OF MANIPULATIVE SURGERY AND ARTHRITIS.

SIR,—I wish to make a preliminary announcement concerning a London clinic of manipulative surgery instituted in response to many requests from medical men and others who feel that some such movement is urgently needed to endeavour to place the subject upon a scientific basis. The clinic is primarily for the benefit of poorer patients in need of manipulative treatment, and the headquarters are at present at 59, Montagu Square, W.1. Treatment in the case of the necessitous poor will be gratuitous. The clinic is held at present on Tuesdays between the hours of 2 and 6 o'clock, and it is hoped, when its activities are in full swing, to arrange classes and demonstrations for practitioners and senior students, who are at all times welcome at the clinic. A scheme is also under consideration for the foundation of an institute for the scientific investigation and modern treatment of injuries and non-tuberculous diseases of joints, particularly the so-called rheumatoid arthritis. Concerning this a further announcement will be made in due course.—I am, etc.,

London, W.1, March 22nd.

A. G. TIMBRELL FISHER.

INSURANCE AGAINST ERRORS OF LOCUMTENENTS.

SIR,—The council of the Medical Defence Union has given careful consideration to the question of affording members of the Union protection when actions are brought against them in consequence of the acts of a locumtenent who is not himself a member of the Union.

Recognizing that a very considerable number of members

are anxious to obtain protection in this respect, even, if necessary, at the cost of an additional premium, the council has decided that in future it may, in its discretion, assume responsibility for any claim made upon a member in respect of the act or omission of any registered medical practitioner whilst temporarily employed as locumtenent for such member. In conferring this additional benefit of membership, the council has decided to require no extra payment beyond the ordinary annual subscription.—We are, etc.,

HERBERT F. WATERHOUSE,
President.

JAMES NEAL,
General Secretary.

Medical Defence Union,
43, Bedford Square, London, W.C.1.
March 23rd.

Obituary.

THE London School of Hygiene and Tropical Medicine has received by cable the distressing news that Dr. W. E. HAWORTH has been killed in a motor accident in Southern Rhodesia. No details are yet to hand. It was only in August last that Dr. Haworth, who was then 60 years of age, entered with enthusiasm upon research work in medical entomology undertaken on behalf of the school, and interesting reports have been received from Dr. Haworth showing with what energy and zeal he was throwing himself into the work. Not long before his last appointment Dr. Haworth was giving proof of his activity, remarkable for a man of his years, by scaling coconut palms at Dar-es-Salaam in the search for mosquito larvae. The result of his researches at that time was embodied in a paper published in the *Transactions of the Royal Society of Tropical Medicine and Hygiene*, which was regarded as an interesting and important contribution to the literature on the subject. Wallace Ellwood Haworth was the son of Robert Edmond Haworth of Christchurch, New Zealand. He studied at Edinburgh University; took his M.B. and C.M. in 1892 and his B.Sc. in Public Health in 1893. From 1896 to 1917 he was in private practice in Southern Rhodesia, and was afterwards on active service with the Rhodesian native regiment in Nyasaland, German East Africa, and Portuguese East Africa. He held various Government appointments between 1920 and 1924, and devoted much time to observations on the breeding of mosquitos in coconut palms. By Dr. Haworth's untimely death the school has sustained a serious loss in the ranks of its research workers, and much sympathy will be felt for his widow in her sad bereavement.

In the death, at the age of 59, of Sir DAVID EVANS, director of the Welsh National Memorial Association, which occurred on March 17th, the tuberculosis service in Wales has lost one of its ablest officers. When in 1911 Mr. David Davies and his sisters, the Misses Davies of Llandinam, decided upon their generous endowment of a national tuberculosis scheme as the first step towards a Welsh memorial to King Edward VII, they found in Sir David (then Mr.) Evans an adviser richly equipped to help the enterprise. With an intimate knowledge of the Principality and its people, he combined a large experience gained in the legal profession and an energy and initiative second to none. He threw himself into the new movement with vigour, and it may truly be said that Wales owes to his administrative ability, combined with the technical knowledge of Dr. Marcus Paterson, then medical director of the association, one of the finest systems of sanatorium treatment, hospital isolation, and area work yet devised for dealing with tuberculosis. As a member of the Consultative Council of the Ministry of Health in Wales, he was in close touch with preventive medicine; while, as the representative of the Memorial Association on the Board of Medicine of the Welsh National School of Medicine, he rendered valuable services at a time when the new school was gathering momentum on the creation of the clinical units. His lifelong interest in the Cardiff Royal Infirmary, and his valuable help in connexion with the linking up of its clinical staff with the School of Medicine, constitute still another debt owed to him by the medical profession.

Dr. DANIEL DE VERE HUNT, who died in Cardiff Royal Infirmary on March 5th as the result of an accident, received his medical education at Queen's College, Cork, and the Royal College of Surgeons, Ireland. He obtained the diplomas L.R.C.S.I. in 1874 and the L.R.C.P.Ed. and L.M. in 1882. He commenced practice in Cardiff about thirty-five years ago, after a previous residence in Oldham, and took a very active interest also in ambulance work. Dr. Hunt was appointed divisional surgeon to the Great Western Railway in April, 1908, chief ambulance corps surgeon to the Cardiff district in 1912, and staff officer for the Priory for Wales in 1919. During the war he raised four voluntary aid detachments, and acted as staff surgeon to the Cardiff Centre Priory for Wales; he was appointed an honorary associate of the Order of St. John of Jerusalem in 1921. He was a member of the British Medical Association.

Universities and Colleges.

VICTORIA UNIVERSITY OF MANCHESTER.

The following candidate has been approved at the examination indicated:

DIPLOMA IN PSYCHOLOGICAL MEDICINE (*Part I*).—R. B. F. McKail.

SOCIETY OF APOTHECARIES OF LONDON.

The following candidates have passed in the subjects indicated:

SURGERY.—C. B. Ball, W. O. R. Fischer, W. H. D. Priest, F. Widdlake.
MEDICINE.—W. O. R. Fischer, B. Horwitz, E. J. Jones.
FORENSIC MEDICINE.—A. C. Hill, H. H. Lakin, I. Rivlin, P. H. Row, G. H. Weeber.
MIDWIFERY.—G. H. Bickmore, W. O. H. Evans, C. F. L. Hazard, A. C. Hill, W. Johnson, R. D. Mason, H. Rundstrom.

The diploma of the Society has been granted to Messrs. B. Horwitz, R. D. Mason, and G. H. Weeber.

UNIVERSITY OF ABERDEEN.

The following candidates have been approved at the examination indicated:

FINAL M.B., Ch.B.—J. Adam, Victoria
C. Emslie, C. E. Forster, Howie,
R. A. B. Jaffray, G. C. Kel Mackay,
Gladys M. E. Martin, W. C. A. Nicol,
A. C. Nicol, *E. A. Paterson, A. M. Ramsay, W. L. Ramsay,
*G. A. Ross, H. Sandler, A. Skinner, Mabel Stephen.
* Passed with distinction.

ANDERSON COLLEGE OF MEDICINE, GLASGOW.

Dr. S. SPENCE MEIGHAN, assistant surgeon, Glasgow Eye Infirmary, has been appointed to the chair of ophthalmic medicine and surgery, and Mr. William Rankin, surgeon to the Glasgow Royal Hospital for Sick Children, has been appointed to the chair of surgery.

UNIVERSITY OF DUBLIN.

TRINITY COLLEGE.

At the spring commencements in Hilary term, held on March 19th, the following degrees were among those conferred:

M.Ch.—T. E. Gordon, W. Taylor (*Ordinis Imperii Britannici Eques Commandator*).
M.B., B.Ch., B.A.C.—Boland, Mabel E. Brittain,
A. B. Brooks, Featley, R. G. Keays, G. G.
M'Farland, J. W. G. Maule, G. A. Miller,
Mary S. Miller, P. F. Palmer, Lucy E. R. Pigott, Margaret W. Pike,
J. V. Pincus, W. C. G. Potts, G. A. A. Powell, D. N. Power, E. Rakoff,
H. J. Roche, D. J. Roux, W. Russell, J. M. Selkon, W. C. Sloan,
C. L. Taylor, G. W. H. Townsend, G. A. Walmsey.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND.

At a special business meeting of the College held on March 19th Dr. Robert James Rowlette, F.R.C.P.I., was elected King's Professor of Materia Medica and Pharmacy in the School of Physic in Ireland, Trinity College, Dublin.

The Services.

ROYAL NAVY MEDICAL CLUB.

The annual dinner of the Royal Navy Medical Club will be held this year at the Trocadero Restaurant, Piccadilly Circus, on Thursday, April 22nd, at 7.30 for 8 p.m. Members who wish to be present are asked to inform the Honorary Secretary, Royal Navy Medical Club, 68, Victoria Street, London, S.W.1, not later than seven clear days before that date.

NAVAL MEDICAL COMPASSIONATE FUND.

A MEETING of the subscribers of the fund to elect six directors will be held at the Medical Department of the Navy, 68, Victoria Street, S.W.1, at 11.30 a.m. on April 23rd.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

THE House of Commons will rise for the Easter Recess on April 1st, and will reassemble on April 13th. This week it has debated the recent crisis in the League of Nations, and has taken the report stage of the Army and Navy Estimates and has discussed general policy on the Consolidated Fund Bill. On this bill the Liberal party proposed to initiate a debate on the Report of the Royal Commission on National Health Insurance.

At the request of the Central Midwives Board Dr. Fremantle has put down amendments to the Midwives and Maternity Bill, which awaits examination by a Standing Committee. One amendment proposes to institute an authorized badge for midwives. Another proposes to alter the provisions of the Act of 1922 by enjoining that (except in emergency) an unqualified person shall only attend a woman in childbirth under the direction and in the presence of a medical practitioner; further negotiation is possible on this point.

The Parliamentary Medical Committee, during its meeting at the House of Commons on March 17th, received three deputations. The first was a deputation from the Joint Council of Qualified Opticians regarding the proposed Opticians Bill for registration, concerning which the Medical Committee had already heard opinions from members of the British Medical Association. The opticians' deputation explained the bill and the relationship proposed with medical practitioners. The Medical Committee took no decision on the matter; opinions appearing to be divided. A deputation was also received from the British Medical Association about the Births and Deaths Registration Bill, which was to come before a Standing Committee of the House on March 23rd. The deputation included Dr. Bone, chairman of the Medico-Political and Parliamentary Committee, Mr. E. B. Turner, and Dr. Courtenay Lord. They suggested amendments to the bill. One proposed that the bill should state definitely that when a medical man was called in to see a body and suspected death from violence or poisoning it should be his duty, not to give a death certificate, but to notify the coroner. A further amendment suggested that the retention of a body more than seven days should be prohibited. The Parliamentary Medical Committee announced that Sir Richard Luce would introduce these amendments. A third deputation attended from the Society of Members of the Royal College of Surgeons. They spoke in support of their petition to the Privy Council, which asks for consideration of their claims along with the request of the Council of the College for a supplementary charter.

The Parliamentary Medical Committee will next meet on April 21st.

Coroners Bill.

The report stage of the Coroners Bill (referred to in a leading article this week at page 582) was set down in the House of Lords for March 25th. In Committee on this bill the House excepted the coronership of the City of London from a clause abolishing franchise coronerships. Lord Strachie proposed that coroners should be made to contribute to a pensions fund. The Lord Chancellor said the difficulty was that coroners were appointed at an advanced age. They were usually either experienced lawyers or experienced doctors who had practised and made a name. The average age at appointment of coroners was something like 50. It was quite impossible to form any superannuation fund by any reasonable yearly contributions from men appointed at the age of 50, and county councils would be left to fix the pension in making the appointment. Lord Strachie withdrew his amendment. On the motion of the Lord Chancellor another clause was modified to enable the Lord Chancellor, with the concurrence of the Secretary of State, to make rules for regulating the practice and procedure at or in connexion with post-mortem examinations as well as inquests. He said this was to enable rules to be made as to post-mortem examinations and the forms of certificate to be sent to the coroners, and matters of that kind. The amendment was accepted and the bill passed through committee.

Births and Deaths Registration Bill.

A Standing Committee of the House of Commons considered the Births and Deaths Registration Bill on March 23rd. Sir Kingsley Wood, at the opening of the debate, said that as a Coroners Bill was before Parliament the Committee would agree that the amendment of the law relating to coroners should be completed in that bill. He would accordingly move amendments deleting all references to coroners from the Births and Deaths Registration Bill. He had the authority of the Home Office for saying that the necessary amendments would be made in the Coroners Bill. Dr. Fremantle concurred in this. Sir Kingsley Wood resisted an amendment proposed by Mr. Looker which sought to enact that no burial should be permitted unless a certificate of death had been issued. Sir Kingsley Wood suggested that the bill went far enough. They should see how it

worked before considering more drastic proposals. The amendment was negative. In resisting a further amendment from Mr. Looker, Sir Kingsley Wood said that cases were frequent when in the distress following a death a funeral party arrived at the grave without the necessary documents. The Government proposed to meet such cases by allowing a written declaration to be made. The Committee should not assume that the majority of the population of England would attempt to dispose of bodies improperly. Mr. Greenwood thought that the bill was too loosely drafted on this point. Other members thought that burial after declaration might become the normal procedure. Sir Kingsley Wood promised that before the report stage he would see whether the proviso could be strengthened. On the motion of Dr. Fremantle "redundant" was then deleted from Clause 1. Several drafting amendments were made in the following clauses on the motion of Dr. Fremantle. One dealt with the proposal of the bill that a registrar might issue a certificate that he had received notice of death. The bill provided that he might do this "upon receiving written notice of the occurrence of a death accompanied by a medical certificate." The amendment made upon Dr. Fremantle's motion provided that the certificate might be issued "upon receiving written notice of the occurrence of a death in respect of which he has received a medical certificate." Dr. Fremantle then proposed to leave out "or Wales", so that the safeguards in regard to the transfer of a body from one country to another should not apply to transfer between England and Wales. "Or Wales" was deleted by a majority. Dr. Fremantle moved that seventy-two hours be substituted for forty-eight hours as the period within which the person effecting the disposal of the body must deliver to the registrar a formal notification of the date, place, and means of disposal of the body. On Clause 4 "Great Britain" was altered to "England" on the motion of Sir Kingsley Wood, who gave assurance that a coroner's certificate would not be needed for removal of a body from England for burial in Scotland unless an inquest had been ordered; otherwise the ordinary procedure enjoined in the bill would be followed. Sir Kingsley Wood said the removal of bodies from England to Scotland were very few during a year. At present the easiest way of getting rid of a body was to ship it out of the country, and for that reason the bill provided for safeguards regulating the removal of bodies out of England. He would ask the Secretary for Scotland to consider whether the clause could not be further amended to prevent inconvenience in the removal of bodies to Scotland. Dr. Fremantle proposed that notice of removal of a body out of England should be given, not to the coroner in whose district the death occurred, but to the coroner in whose district the body was lying. The amendment was accepted. On Clause 7, dealing with stillbirths, Sir Richard Luce asked whether the person in charge of the cemetery was to decide whether a child was stillborn. Sir Kingsley Wood said he would not be able to do so. In the case of a child which had nearly approached the age of 26 weeks, the limit provided in the bill, the sexton would doubtless err on the side of caution and demand a certificate of stillbirth. Sir K. Wood added that in his opinion the registration of stillbirths was one of the most valuable provisions of the bill. On the clause enjoining the delivery of every certificate of cause of death by the medical practitioner to the registrar, Dr. Fremantle moved that the certificate should be delivered "forthwith." Mr. Groves suggested a limit of twenty-four hours, and said that in the opinion of undertakers there was too much delay under the present law. Sir K. Wood preferred the word "forthwith," which would cover the case of the doctor who desired to consider whether he should give a certificate at all. Mr. Groves suggested a limit of forty-eight hours, and said he was confident that doctors in the country would not usually avail themselves of that latitude. Dr. Fremantle's amendment was adopted. Sir R. Luce moved an amendment declaring that the duty of transmitting the certificate to the registrar, which the bill imposed on the medical practitioner, should be "by post, free of expense to himself." Sir K. Wood said the Treasury would have to be consulted on the point. The certificate might be printed with a postage prepaid imprint, or the registrar might repay the postage to the doctor. Sir R. Luce's amendment was then withdrawn after he had pointed out that as secrecy was the intention of the bill the certificate could not be sent by halfpenny post.

Sir Richard Luce moved to add an amendment declaring that—

If the cause of death is unknown to the medical practitioner called upon to certify, or if he is of opinion that death has arisen from or been accelerated by any violence, directly or indirectly, or through neglect, or poison, or other unnatural cause, or has followed as an immediate sequence to the administration of an anaesthetic, he shall not grant any certificate of death, but shall forthwith report the circumstances to the coroner for the district in which the death has occurred.

He said that under the Act of 1874 the duty of a medical practitioner was to give a certificate. Many coroners had objected to doctors doing this in cases of accident or of death under an anaesthetic. The amendment suggested a method, which he thought best, that the doctor should inform the coroner of his doubts before giving the certificate. A second method would be to refuse the certificate and inform the relatives that they must inform the coroner or the police. A third method would be for the medical man to give the certificate and leave the registrar to inform the coroner. He thought the two latter methods not so good as the first. Sir Kingsley Wood said that those who had asked Sir R. Luce to put forward this clause had acted under a misapprehension. At present a doctor was under a common law obligation to inform the coroner of sudden deaths or suspicious deaths. In addition, he had a statutory duty to certify

the cause of death as he knew it whatever the circumstances. If both these duties were carried out there would be no need for the new clause. But he agreed that there had been misapprehension, and he would consult the Home Secretary before the report stage to see whether that Minister could consult coroners, as remarks made by some of them were largely responsible for current misconceptions on the subject. Dr. Davies said that in the district which he represented the arrangement suggested by Sir R. Luce had been in force for thirty years and had worked well.

Sir Richard Luce withdrew his amendment. Clause 6 was added to the bill, and the Committee adjourned till March 25th.

Economy Bill.

The Economy (Miscellaneous Provisions) Bill was read a second time in the House of Commons by 322 to 142 and was sent to a Committee of the whole House. Mr. Lloyd George, in criticizing the proposal to reduce the State contributions to National Health Insurance, said that in 1911 Unionist critics of the insurance scheme had declared that it offered too low benefits for the charge. The reply had been: "We have no doubt at all that as a result of a great system of health insurance with improving medical benefits, with the removal of the anxieties that oppress a sick workman when ill, and not able to maintain his household, there will be such an improvement in the health of the people that the benefits will be increased." All that had turned out to be quite true, and the Royal Commission on National Health Insurance had recommended further benefits. The House was now going back on that bargain. It was a mean way of making money to pluck feathers out of the pillow of a sick man. There would be no saving, as the money to be saved by Mr. Churchill would have to be provided for the sick out of the rates. Mr. Neville Chamberlain said the bill did not touch the surpluses accumulated under the first valuation, amounting to over £17,000,000, nor the surpluses disclosed or to be disclosed under the second valuation, amounting, including the carry forward, to £45,000,000. It did not touch the surplus accumulated between the second valuation and December 31st, 1925. It only slowed down as from this year the accumulation of further surpluses in the funds of the approved societies. Mr. Chamberlain further pointed out that when the original Act began to work it was found that 6s. was not enough for the cost of the doctors, and that cost went up to 11s. in one year. By an amending Act a new arrangement was made under which the cost of the doctors on the fund was raised from 6s. to 7s. The approved societies came to the State and the State paid the difference, and from that time up to 1922 the State had paid for the extra cost of the doctors, which was not provided for under the bargain or contract said to have been made in 1911. In this way the State had paid an extra contribution of no less than £19,000,000. Mr. Chamberlain also noted that in 1920, when Mr. Lloyd George was Premier, an Act was passed reducing the State contribution for insured women from one-fourth to two-ninths.

Mr. Lloyd George subsequently published a letter protesting against Mr. Chamberlain's comparison between this action in 1920 and the proposals in the Economy Bill.

Answering Mr. Ramsden, Mr. Chamberlain said he was not in a position to make a statement on the introduction of legislation to give effect to all or any of the recommendations of the Royal Commission on National Health Insurance.

Sir Kingsley Wood informed Sir Frederick Hall, on March 22nd, that on the closest estimate of which the conditions permitted the aggregate amount of the surpluses of approved societies at December 31st, 1925, was about £65,000,000. A society was only allowed to apply to the provision of additional benefits such parts of its surplus as were certified by the valuer to be disposable.

Royal-Naval Medical Service.

On a vote for £14,718,000 for wages of officers and men in the navy, Mr. Ammon said that there had been a considerable amount of criticism of the cost of the medical service in the navy. The First Lord had promised to look into the matter and he would be glad to know the result of his investigation. The complaint made was that, compared with other services, the charge per head was excessive. Had inquiries been made during the past year into the possibility of bringing the cost of the medical service within more reasonable limits? The First Lord should also give consideration to the suggestion that some economy could be effected by the pooling of the medical systems of the three services.

Mr. Bridgeman said that he understood Mr. Ammon's remark about medical services was that there should be more co-operation than existed at present. A great deal was being done in that direction. So far as hospitals were concerned they were gradually trying to use the same hospitals for the other services as well as the navy, sometimes abolishing the navy one and using the other and vice versa. In that way improvement was undoubtedly possible. He thought that there were many difficulties in the way of a common medical service for the three branches. He doubted very much if they could recruit a doctor if he did not know to which of the three services he might be sent.

Sir Gerald Hohler said that there was an opportunity to try to effect economies by combining the medical services at Chatham. The navy and the army were living together in the same town, and they had there the finest hospital in the country. The House agreed to the vote.

Smoke Abatement.

The Public Health (Smoke Abatement) Bill was read a second time in the House of Lords on March 23rd. Viscount Gage, Lord-in-Waiting, who moved the second reading, said that it was intended to follow the precedent of previous bills on the subject, to extend the scope of certain Acts and to encourage a more rigid enforcement of existing laws. The first clause gave power to take proceedings irrespective of the colour of the smoke. It also defined the expression "smoke" as including soot, ash, grit, and gritty particles. The bill also gave power to the local authorities to prescribe standards for the emission of smoke and to require that certain new buildings should be provided with arrangements for smokeless heating. The Minister of Health, he said, was anxious to reduce the volume of domestic smoke, which was responsible for at least 50 per cent. of the pollution of the atmosphere. Dwelling-houses would be exempt, because the installation of smokeless heating in them would not be compatible with the rapid and inexpensive provision of working-class houses, which were urgently needed. People were exceedingly conservative in their domestic habits, and no cheap form of smokeless fuel was at present available for domestic consumption. Under Clause 3, the Minister of Health, after a public inquiry and in consultation with the local authorities or other interests concerned, could make orders extending the list of noxious or offensive gases mentioned in Section 27 of the Alkali, etc., Works Regulations Act, 1906. Another clause exempted ships from the operation of the bill. The measure would not bring the complete disappearance of fogs, or of smoke which had such unpleasant and harmful effects, but the Minister of Health had gone as far as he could without adding to the cost of living and of production and manufacture.

Lord Newton said that the bill, if amended in Committee, might do much good. The waste from burning raw coal at present was enormous, but a much greater question was that the measure affected the general amenities of life.

Earl De La Warr asked for an inquiry with a view to terminating the metallurgical exemptions contained in the bill, and to forcing model by-laws on local authorities.

Viscount Novar said he was disappointed that the bill did not apply to Scotland.

The Marquess of Salisbury (Lord Privy Seal) said he agreed that the need for the bill was at least as great in Scotland as in England, but the law was not the same in the two countries. The Government had not overlooked the matter and intended to introduce a separate bill for Scotland.

The bill was read a second time.

Colonial Medical Service.—Mr. Amery, answering Mr. Forrest, said he had received a deputation from the British Medical Association on March 5th with regard to the conditions of employment of medical officers in the Colonial Service, more especially in East Africa. Correspondence with the Association continued.

Pensions.—Major Tryon announced that at the end of February 12,420 officers, 185 nurses, and 265,900 other ranks were in receipt of life pensions from the Ministry of Pensions. Recipients of 100 per cent. pensions numbered 1,220 officers, 56 nurses, and 16,200 other ranks. Of the life pensions to officers 64 per cent. were due to wounds and injuries, of those to nurses 17 per cent., and of those in other ranks 70 per cent. At the same date 2,542 nurses had received pensions for war service. Approximately 1,830,000 persons were on the books of the Pensions Ministry for issue of pensions or allowances. The rate of diminution was slowing down, and it was estimated that in 1926-27 the decrease would be 7 per cent. Answering Mr. Pielou, Major Tryon said that seven out of the twenty most highly paid posts at the Ministry of Pensions were held by non-service men. Since March, 1923, forty-eight medical officers, all of whom had served with the forces during the war, had been appointed to the establishment.

Psycho-analysis.—Captain Fairfax asked the Home Secretary, on March 22nd, on what grounds, and to what extent, he had sanctioned the practice of subjecting juvenile offenders to experimenters in psycho-analysis; and what precautions he was taking against any possibly dangerous results. Sir William Joynson-Hicks said he had not sanctioned any such experiments, nor had he any intention of doing so. The question whether any further provision should be made for the medical examination of young offenders—a very different matter—was being considered by the Committee now inquiring into the treatment of young offenders.

Grade A Milk.—In reply to Mr. A. Williams, Mr. Chamberlain said that approximately 200 herds were producing certified or Grade A (tuberculin tested) milk. The cows in milk in these herds and all the animals in contact with them were required by the Milk (Special Designations) Order to be submitted to the tuberculin test. Calves were not usually kept in contact with these cows, and consequently there was no necessity for young stock to be tested until introduced for milking purposes. If calves were kept in contact with the cows they must be tested at the time of the general tests of the herd. Young heifers and bulls which were not associated with the milking cows had not to be tested for tuberculosis.

An Operation on a Schoolboy.—On March 22nd Mr. Hayes asked the President of the Board of Education whether he was aware that a school medical officer of the Liverpool education authority performed a surgical operation on a scholar, aged 13, in school, without

the parents' permission, using ordinary non-surgical scissors, iodine gauze, common soap, stitching the wound with ordinary needle and sewing cotton, and that the boy died three days later; whether there had been any breach of the regulations, and, if so, to what extent; and whether, in view of the distressed circumstances of the parents, consideration was being given to the question of a generous grant from public funds. Sir J. Pennefather also asked a question on the same subject. Lord Eustace Percy replied that he was aware of the occurrence, which he deeply deplored. At the coroner's inquest the jury, after hearing the medical evidence, found that the boy's death was due to septicaemia from a wound on the finger and was in no way connected with the operation. The performance of this operation appeared to have been a contravention of the local authority's instructions to their school medical officers and of the practice of the school medical service. Mr. Hayes asked how far the responsibility of the local education authority went in respect of the operation performed on this child during the time that he was under the authority's control. Lord Eustace Percy replied that he did not know whether Mr. Hayes was referring to a legal or a moral responsibility. He could not give a legal opinion on the matter. Mr. Hayes asked whether, if there was no legal responsibility, or even if there was, it would not be handsomer that this matter should be dealt with by an *ex gratia* grant. Lord Eustace Percy said that he had no power to make any grant. That was a matter for the local authority, who, he was sure, were impressed with its importance.

Open Dustcarts.—In reply to Mr. Campbell, Sir Kingsley Wood said the Minister of Health did not know how many local authorities now employed open dustcarts. The Minister had no authority to make the use of automatic closing dustcarts obligatory on local authorities, but local authorities were increasingly making use of improved vehicles. Colonel Applin asked whether the Minister would take steps to compel the local authorities to pass by-laws that their dustcarts were to have air-tight covers. Sir Kingsley Wood said the Minister had no such power, and there was also the question of cost. Local authorities had power to deal with the matter.

Baker's Dermatitis.—On March 23rd Sir Kingsley Wood, replying to Mr. Harland, said the Minister of Health was aware of the prevalence in this country of the disease known as baker's itch. This disease, which was not notifiable, was investigated by the medical department of the Ministry of Health in 1922, and these investigations did not disclose any reasons why it should be made notifiable. The Ministry had no evidence to show that the disease was due to the use of chemicals in the bleaching of flour. Sir Frederick Hall asked whether the disease was infectious or contagious. No answer was returned.

Chemicals in Flour.—On the same day Sir Kingsley Wood informed Mr. Harland that the Bread Acts made it an offence to put into flour any ingredient or mixture not the real and genuine produce of the corn or grain. It was doubtful, however, whether this provision would be held to prohibit the use of gases for bleaching purposes. A departmental committee was at present considering whether it was desirable in the interests of public health that the treatment of flour with chemical substances should be prohibited or restricted.

Small-pox.—On March 23rd Mr. Groves asked the Minister of Health whether the incidence of small-pox had increased or decreased since the operation of the present regulations affecting exemption from vaccination. Sir Kingsley Wood replied that it was presumed that the hon. member was referring to the Order issued by the Minister of Health's predecessor (Mr. Wheatley), which had the effect of reversing an Order issued by him on July 20th, 1923, and of reinserting the form of statutory declaration of conscientious objection in the notice of requirement of vaccination handed to the parent or guardian when the birth of a child was registered. The Order of the former Minister of Health came into force on October 1st, 1924, and since that date the incidence of small-pox had considerably increased. Mr. Groves, in a supplementary question, asked whether it were not true that since the number of exemptions had increased small-pox had diminished, and whether the Minister would not change the law to provide that people should be vaccinated only if they desired it.

V.A.D.—Sir L. Worthington-Evans, Minister of War, stated, on March 23rd, that as the Voluntary Aid Detachment personnel would be employed principally in general hospitals in the event of war, it was considered that they derived more useful experience from the training which they received in military hospitals than it would be possible to obtain by training with Territorial divisions.

Arsenic in Apples.—On March 23rd the Minister of Health stated that he had received representations from the Surbiton District Council about fruit exposed for sale and found to contain arsenic. The present Imported Food Regulations enabled port and riparian sanitary authorities to seize and destroy any imported food which was unfit for human consumption, and he did not think that it would be practicable to strengthen these regulations in any way short of imposing an absolute prohibition on the importation of apples, a measure which would not, in his view, be justified in the present circumstances. He was not aware of any case in which an excessive quantity of arsenic had been found on home or empire grown apples.

Asylum Officers.—In the House of Commons, on March 23rd, Mr. Taylor presented a bill to amend the Asylum Officers Superannuation Act, 1909, and it was read the first time.

Medical News.

At the annual general meeting of the governors of the National Hospital for the Paralysed and Epileptic, Queen Square, held on March 23rd, it was announced that through a supplementary Royal Charter the name of the institution will be changed to "The National Hospital, Queen Square, for the relief and cure of diseases of the nervous system, including paralysis and epilepsy." This step has been taken because the present title leads to the belief that the hospital is exclusively for paralysed and epileptic people. Moreover, patients suffering from other nervous diseases are deterred from coming owing to the fear associated with epilepsy, although actually only a small percentage of the patients are epileptic. In addition, people are inclined to gather from the old title that the hospital is an institution for incurables. The majority of the cases admitted are upon the recommendation of members of the medical profession, to whom the hospital is already widely known either as "The National Hospital" or "Queen Square Hospital."

The third annual congress of the Incorporated Association of Hospital Officers will be held on Friday, April 16th, at the Central Hall, Westminster. It will be opened at 10.30 by the president, Sir Arthur Stanley, G.B.E., and a paper will be read by Miss R. E. Derbyshire, Matron of University College Hospital, on the nursing requirements of a modern hospital. In the afternoon Mr. E. W. Morris, C.B.E., house governor of the London Hospital, will open a discussion on the geographical distribution of hospitals in relation to community requirements. At a dinner to be held in the evening at the Holborn Restaurant the Earl of Arran will be the chief guest. Full particulars can be obtained from the Secretary, 28, Bedford Square, W.C.1.

The Fellowship of Medicine announces that on March 31st, at 2 p.m., a demonstration in clinical surgery will be given by Mr. A. Tudor Edwards at the Westminster Hospital general course. On April 15th a similar demonstration will be given by Mr. W. E. Tanner at the Prince of Wales's General Hospital, Tottenham. On March 30th and April 1st Dr. Low and Dr. Manson-Bahr will give lecture demonstrations, illustrated by cases, at the London School of Hygiene and Tropical Medicine, at 2 p.m. A two weeks' clinical course will start at St. Peter's Hospital on April 19th, and a series of four lecture demonstrations on treatment by electrotherapy will be given by Dr. C. B. Heald, at the Royal Free Hospital, at 5.15 p.m., each Wednesday, beginning on April 14th. A special all-day course in proctology will be held at St. Mark's Hospital from April 19th to 24th, and a course in general medicine, surgery, and the specialties at the Bollingbroke Hospital, for two weeks starting April 19th. Copies of all syllabuses and of the general course programme may be had from the Secretary of the Fellowship of Medicine, 1, Wimpole Street, W.1.

A SPECIAL course of lectures and demonstrations will be delivered at the Ancoats Hospital, Manchester, on Thursday afternoons, commencing April 8th, when Dr. Langley will give the first of a series of three on diabetes in general practice. On April 23th, May 6th and 9th Mr. McEvedy and Dr. Twining will deal with the surgical dyspepsias. Tea will be served at 3.45 p.m. and the lectures will commence at 4.15.

A BUSINESS meeting at which it is proposed formally to inaugurate the Association of Special Libraries and Information Bureaux will be held at the Institution of Mechanical Engineers, Storey's Gate, S.W.1, at 2.30 p.m., on Monday, March 29th. All interested are invited to attend. The association (to which several references have been made in our columns) is being formed to facilitate the co-ordination and systematic use of sources of information in science, industry, commerce, and public affairs generally; when fully developed it will function as a clearing-house for those wishing to get into touch with specialized knowledge.

APPLICATIONS for the Rose Research Fellowship in Lymphadenoma, value £600 per annum, must be sent in by April 21st to the Professor of Pathology, St. Bartholomew's Hospital, from whom further information may be obtained. The research must be carried out at St. Bartholomew's Hospital under the direction of the Professor of Pathology. The fellowship may be tenable under annual re-election for four years.

A SPECIAL two weeks' post-graduate orthopaedic course will be held at the Royal National Orthopaedic Hospital from April 12th to 24th. Lecture demonstrations will be given at 11 a.m. each day by the staff, and members of the course are invited to attend the practice of the hospital, including operations before the lecture demonstrations, and the out-patient department in the afternoons. The fee for the course is two guineas, and applications should be sent in by April 7th to

the secretary of the hospital, 234, Great Portland Street, W.1, or to the Secretary of the Fellowship of Medicine, 1, Wimpole Street, W.1.

THE annual meeting and festival dinner of the Irish Medical Schools' and Graduates' Association was held at the Piccadilly Hotel on March 17th, with Surgeon Vice-Admiral Sir Joseph Chambers, K.C.B., Medical Director-General R.N., in the chair, and Sir Michael O'Dwyer as the guest of the evening. The association, which was founded in 1878, has for its object the support of efforts to improve the status of the profession, with especial regard to medical practitioners holding Irish degrees or diplomas. It promotes social intercourse among those who have studied at an Irish school of medicine, and an autumn meeting and dinner is also held in London. The annual subscription is 5s., and applications for membership should be addressed to Dr. F. R. Holmes, 11, Lancaster Road, South Hampstead, N.W.3.

A COMPLIMENTARY dinner was given in honour of Dr. James Thomson, on March 12th, in recognition of his completion of forty-six years as a medical practitioner in Irvine, Ayrshire. The guests included Professor Glaister of Glasgow University, and Dr. Chalmers, who recently resigned the position of chief medical officer for Glasgow. During the evening Dr. Thomson was presented with a diamond ring, and his wife with a silver tea service; his daughter, Dr. Isabel Thomson, who is in partnership with him, received a watch.

At a meeting of Jewish members of the medical profession, held in London on March 14th, it was decided to form a medical branch of the society "Friends of the Hebrew University of Jerusalem." Sir Philip Hartog, president of the society, emphasized the great importance of the research work now in progress in the biochemical and microbiological institutes of the university in Jerusalem. Dr. M. D. Eder stated that the first institute opened at the university had been for medical research, with special reference to the investigation of serological, hygienic, and parasitological problems in Palestine and the neighbouring countries. Post-graduate study for medical practitioners was also being organized. The chairman of the medical branch is Dr. A. H. Levy and the secretary Dr. M. Sourasky.

THE Royal College of Physicians of London will be closed from Friday, April 2nd, to Wednesday, April 7th, both days inclusive.

DR. C. W. DEAN, on the occasion of his appointment as consulting surgeon to the Royal Lancaster Infirmary after forty-one years' service at the institution, has been presented by the general committee, the medical committee, the matron, and staff, with a silver salver in appreciation of his long and devoted voluntary service.

DR. ROBERT A. LYSTER, county medical officer of health for Hampshire, has been elected president of the Association of County Medical Officers.

DR. JOHN GRIFFITHS, J.P., of Llandrindod Wells has been appointed sheriff for Radnorshire.

THE *Journal of Physiology* will be conducted in future by the Physiological Society, which has appointed an editorial committee of four. The change has been rendered necessary by the lamented death of Professor J. N. Langley, who had been responsible for editing this very valuable periodical.

THE League of Red Cross Societies, the office of which is at 2, Avenue Velasquez, Paris, has published a calendar for 1926 illustrated with reproductions of posters designed by the Red Cross societies of various nations, and the prize poster in the international competition organized by the League.

THE sixth annual congress known as the Journées médicales de Bruxelles will be held at Brussels from June 26th to 30th.

It is announced by the Great Western Railway Company that on and after April 1st "certified" milk alone will be used on the restaurant cars attached to all the express trains to and from Paddington.

THE Oxford University Press announces for early publication an illustrated monograph by Dr. Jamieson B. Hurry, entitled "Imhotep, the Vizier and Physician to King Zoser and afterwards the Egyptian God of Medicine."

DURING the period September 13th to November 7th, 1925, 2,577 cases of plague occurred in Java, all of which were fatal.

THE following officers have been elected in the International Society for Combating Tuberculosis and Cancer for the year 1926: Professor Charles Richet, president of honour; Dr. Loir, president; Professor Rappin, Dr. Bailler, and Dr. Joseph Thomas, vice-presidents; and Dr. Simionescu, general secretary. The monthly meetings will be held in the Hôtel du Dispensaire Marie de Roumanie, 17, Square de Messine, Paris, on the fourth Friday of each month.

THIRTY-THREE cases of typhoid fever, of which three were fatal, have been traced by the Michigan State Health Department to a woman who assisted in serving a church dinner.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the **BRITISH MEDICAL JOURNAL** alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the **BRITISH MEDICAL JOURNAL** must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the **JOURNAL**, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the **BRITISH MEDICAL JOURNAL** are **MUSEUM 9861, 9862, 9863, and 9864** (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are:

EDITOR of the **BRITISH MEDICAL JOURNAL**, *Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Mediscera Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 4737 Dublin), and of the Scottish Office, 6, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 4361 Central).

QUERIES AND ANSWERS.

INCOME TAX.

Succession: Appointments not Retained.

"E. B." writes: H. and B. were assessed under Schedule D as partners, to include in one sum the salaries of all appointments. H. retired and B. took W. into partnership, but the new firm did not obtain two of the appointments previously held by H. Can B. and W. deduct the value of these appointments from each year's takings?

* * The case of Whelan v. Henning does not govern these facts, as the judges expressly declined to say that the rule there laid down would be applicable to the assessment of profits from a trade or profession. We are clear that the salaries of specific offices are in strict law assessable separately and not under Schedule D, and that therefore B. and W. are entitled to exclude the earnings of such appointments from the Schedule D average. But some caution is advisable because if they hold other appointments they may find themselves in a difficulty in obtaining the allowance of expenses referable thereto—in fact, that difficulty is the origin of the pressure brought to bear by the medical profession for the inclusion of salaries, etc., in the general Schedule D assessment. An alternative which "E. B." may like to consider is to accept the assessment, and if at the end of the new firm's first year he finds that the profits have fallen short of the sum assessed by reason of some specific cause—that is, the discontinuance of the appointments in question—he can claim to have the amount of the assessment reduced to the actual profits of the year of assessment.

LETTERS, NOTES, ETC.

ANOTHER DISEASE DUE TO FASHION.

DR. H. W. BARBER (London, W.) writes: With regard to the note under the above title by "C. K." in your issue of March 20th (p. 554), the condition to which your correspondent doubtless refers is seborrhoeic dermatitis, which, as he suggests, is particularly likely to spread downwards from the scalp in women with seborrhoeic scalps whose coiffure is so arranged that pads of hair completely cover the ears. The modern closely fitting hat is certainly an aggravating cause. The patients invariably have seborrhoea of the scalp, and a heavy infection with the "bottle bacillus" and staphylococci. The hair-pads and the closely fitting hat act as fomentations, and encourage the active growth of the micro-organisms responsible, providing for them exactly the conditions they require—namely, warmth, moisture, accumulation of the abnormally acid excretions of the sebaceous and sweat glands, and absence of light and air. Decomposition of the secretions takes place with secondary eczematization, producing the "denn'd moist unpleasant" surface referred to.

ESTIMATION OF SUGAR.

DR. J. BARKER SMITH (101, Holmdene Avenue, S.E.24) writes: I have received a courteous letter from Dr. John Livingston of Barrow-in-Furness with respect to my using the term "my char test." He writes: "I thought it was mine." He informs me that he described a char test in the **BRITISH MEDICAL JOURNAL** of May 6th, 1922. Dr. Livingston

has no doubt discovered the char test independently of myself; but I described a char test in the *Medical Press* of November 3rd, 1920, in an article on the silica spoon in the surgery. What Dr. Livingston, I think, has not described is the adhesive quality of the sugar char of one droplet of urine evaporated gently to an extract, and that extract strongly charred, plunged into water, and rubbed with the soft fingertip. The residue char of sugar remains and is in ratio to quantity of sugar. As I said, a fraction of a milligram of sugar affords evidence of its presence. There is yet another important feature to be noted both in Dr. Livingston's char test and my own—namely, that urine of medium specific gravity containing on an average three or more per thousand of sugar is often associated with eczema, boils, nettle rash, etc., and the patients must be treated as potential diabetics with respect to starch and sugar. I should be pleased to send any reader a reprint of an article on this relation of this small amount of sugar in the urine which the char test reveals and which has been passed over by other tests. The same aspect applies to the blood sugar and eczema, as we see in the work of Dr. H. Haldin-Davis and Dr. L. Wills, published in the *British Journal of Dermatology and Syphilis*, August-September, 1925.

SOMATIC ORIGIN OF MALIGNANT DISEASE.

IN the course of a letter received a few weeks ago Dr. HERNAMAN-JOHNSON (London, W.), referring to a paper by Mr. C. R. Crowther on the somatic origin of MEDICAL JOURNAL, January 23rd, p. 1, if the body could be induced to ignore naut growth it would remain harr might conceivably induce this attitude of passivity—receives some support from certain experiments conducted by Dr. J. A. Hadfield at the Royal Naval Hospital, Haslar, in 1917. A subject was discovered so sensitive to hypnotic suggestion that blisters could be raised on him at will. With the consent and co-operation of the patient, experiments were performed with burning cigarette ends. It was found that a suggestion that there should be no pain resulted in an entire lack of reaction. The small portion of tissue actually destroyed came away as an aseptic slough, and the area healed in a few days without pain or discomfort. One could well believe that were such a patient the subject of cancer, the growth might be favourably affected by suggestion. In the above case we have a definite example of an irritant being rendered harmless by causing the body to ignore its presence, but apparently something more is needed than paralysis of sensory nerves if the spread of a cancer is to be stopped. I have recently had under my care a patient with rodent ulcer of the nose who, being also a sufferer from severe trigeminal neuralgia, had been successfully treated by alcohol injections. The anaesthetic area included one side of the nose: the rodent ulcer extended about half an inch on either side of the mid-line. It was decided to treat it by x rays. A preliminary test by an erythema dose of ultra-violet light showed no redness in the anaesthetized side of the nose. Nevertheless, under x rays healing proceeded equally on both sides, and was complete in about six weeks. Some months later the disease recurred, and again attacked both sides of the nose to an equal extent, the hemianaesthesia being still maintained. This clinical experiment would seem to show that both the healing of a cancer under x rays and the direction of its spread are—or, at any rate, can sometimes be—-independent of the functioning of the nerves of sensation. Even after the blocking of the sensory nerves supplying a part, this part retains its organic unity with the body as a whole. It is still, if I may use the expression, represented in the somatic consciousness, and I fear there is no way of putting Dr. Crowther's theories to the test of practice unless perhaps, by the lucky chance of finding a superficial cancer in a subject specially susceptible to hypnotic suggestion.

ANTIMONY IN EYE DISEASE.

DR. F. G. CAWSTON (Durban) writes: In the English edition of E. Merck's annual report for 1926, among reviews of articles appearing in the **BRITISH MEDICAL JOURNAL** and elsewhere, I notice that I am said to recommend "antimony (even in the form of ointment)" in tuberculous affections of the eyes. I do not see how any statement that I have made can be thus interpreted, and wish to dissociate myself from the use of antimony (either in solution or in ointment) in eye conditions of any kind.

ERRATUM.

MR. A. LEYLAND ROBINSON (Liverpool) writes to correct a slip in the typewritten report of the proceedings of the North of England Obstetrical and Gynaecological Society, published in our issue of March 13th (p. 483), where it was stated that a fibromyoma would be called a "dermoid" by some pathologists. The word should be "desmoid."

MESSRS. H. K. LEWIS and Co. have this month issued from their second-hand department two catalogues—one of early scientific works and biographies and the other of early medical works. Both catalogues are noteworthy for the number of interesting and important books and for the very reasonable prices. The catalogues are sent gratis and post free to any address.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 47, 48, 49, 52, and 53 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 50 and 51. A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 103.

Lumleian Lectures ON ENDOCARDITIS.

BY

SIR THOMAS HORDER, Bt., K.C.V.O., M.D.,
PHYSICIAN TO ST. BARTHOLOMEW'S HOSPITAL.

LECTURE I.*

My first and pleasing duty is to thank you, Sir, and the Censors of the College, for the honour of my appointment to the post of Lumleian lecturer. The gratification which I feel is tempered by humility when I recollect the long line of distinguished Fellows who have held this lectureship, a line which includes the illustrious name of Harvey. A man of my temperament must needs be appalled by such knowledge, and though my mind is thrilled by the thought that the subject which I have chosen for these lectures is not distinctly related to matters which the greatest of our Fellows illumined by the light of his genius, I tremble at another thought—my incapacity to prove myself worthy of your choice. I shall be satisfied if a few of my audience, generously disposed, may feel helped by reconsideration of old facts by a frank effort to discriminate between what we do and what we do not know, and by the exercise of some care in suggesting how the present gaps in our knowledge may perhaps be filled, whether by clinical observations or by laboratory research. I shall resist the vanity of trying to say all that can be said on so large a subject, rather contenting myself by selecting certain features which overlap with my personal experience and reflections.

CARDITIS.

It may be advanced that in these days, when more exact knowledge of the inflammatory changes taking place in the heart as the result of rheumatic infection has led us to the realization that the lesion produced is a pancarditis rather than an endo-, peri-, or myo-carditis, the subject of endocarditis has become one of secondary importance. But given this concept of the effect of the rheumatic virus upon the heart, there has arisen, *pari passu* with its recognition, a growing interest in another type of heart infection in which, as is generally admitted, the brunt of the invasion and of the interaction between the infecting agent and the tissues certainly comes upon the endocardium—I refer to that group of infections which is for the nonce termed "bacterial." Of the growing importance of this type of endocarditis, which, but for the objection of adding one more name to a nomenclature already overburdened, might justly be called, in contradistinction to the rheumatic type, "endocarditis vera," we are all fully aware. I shall ask no indulgence for making it the main purpose of these lectures, nor for bearing it constantly in mind when dealing with other types of endocarditis, with one and all of which it has important relations.

I know of no classification of cases of endocarditis which is scientific, and therefore none that is helpful. Nor do I propose to offer one. If it be true that to have overcome the desire to classify is to have attained a little wisdom, then in this matter I have attained a little. A mere recital of the known infecting agents causing a morbid condition is not a classification, and in the case of endocarditis such a recital must perforce at present find the cause of the majority of cases lacking. I propose to proceed without a classification. I shall deal first with endocarditis as it results from rheumatic and syphilitic infection; I shall then consider the influence upon the endocardium of certain factors which are not, so far as we can judge, microbial; I shall follow this by a statement of our present knowledge of so-called "bacterial" infections; and I shall conclude by considerations of pathogenesis, prognosis, and treatment.

It was in the course of his Lumleian Lectures in the

* Delivered before the Royal College of Physicians, London, on March 23rd.

year 1894 that Sturges preached the doctrine of rheumatic carditis. Sturges's subject was "Heart inflammation in children," and he laid emphasis upon the fact that rheumatic heart affections in children were almost always both endocardial and pericardial. Although he noted the frequency with which the myocardium was also involved, he thought this occurred as the result of the pericardium having become adherent. This idea was probably a survival of the teaching current before this time, and indeed still prevalent at the time of Sturges's lectures. In Fagge and Pye-Smith's excellent textbook, in the edition appearing three years prior to Sturges's reference, occur the words: "there is no true carditis as there is no true inflammation of the brain. The inflammations of the heart do not directly concern the muscle but the covering and the lining membranes." When this was written careful histological examination of the myocardium in rheumatism had not been undertaken, and, I might add, encephalitis was not prevalent.

It is significant of the slowness with which ideas, however lucidly stated and however logically supported, gain permanent and practical acceptance in medicine that the doctrine so ably advanced by Sturges thirty-two years ago still requires, and receives, reiteration to-day. The growing conviction of clinicians that the heart was seriously involved as a whole, and from the first, in most severe cases of acute rheumatism, coincided with more critical investigation into the state of the heart wall in fatal cases; the discovery by Aschoff of the nodes which bear his name, and the confirmation of these and other changes by many histologists, put this conception of the unity of the cardiac inflammation in this disease upon a firm basis.

FREQUENCY OF CARDITIS IN RHEUMATISM.

Norman Moore, the Lumleian lecturer in 1909, when treating of "Rheumatic fever and valvular disease," advanced the view that the endocarditis of acute rheumatism was the "central condition in the disease." According to Norman Moore, "endocarditis is always present" in acute rheumatism. "The conclusion to which I wish to attain," he says, "is that every case of rheumatic fever, whether the pains in the joints are slight or severe, is a case of endocarditis, and that the condition of the endocardium is not to be regarded as a frequent complication but as the essential and invariable feature of the disease." Again, "If no evidence of endocarditis is to be found throughout an illness of which a symptom is arthritic pain, then that illness is not rheumatic fever, and the arthritis has some other cause." According to this view, the various peripheral expressions of the rheumatic infection, such as arthritis, the cerebral symptoms, the lesions in the skin and subcutaneous tissues, etc., are secondary to the heart affection. Whether he considered the mechanism by which these peripheral symptoms arose to be by a process of embolism or no Norman Moore did not say, but quite recently Krogus has taken this view, considering the symptoms both in acute rheumatism and in gonorrhoeal rheumatism to be metastatic in nature. The alternative conception, of a virus which invades the blood stream and exercises a special affinity for heart muscle, serous membrane, subcutaneous tissue, skin, and certain parts of the brain, so that more or fewer of these structures are involved structurally and functionally at the same time, seems rather more probable in the case of acute rheumatism.

Be the mechanism of the infection what it may, we have become satisfied concerning two points in relation to heart affections incident upon acute rheumatism: (1) that there is involvement of the heart in so great a proportion of the cases that it is wise to assume that it may be involved in all, and this even in the absence of any direct evidence by physical signs; (2) that the inflammation, especially in children, is of the nature of a carditis.

Carey Coombs complains that the subject of rheumatic heart disease is still divided up in even the most recent textbooks under all sorts of headings, and is therefore only dealt with "in scraps" rather than as an entity possessing a specific cause and presenting a clear clinical and pathological picture. This complaint seems reasonable, and the great importance of the matter justifies the

strenuous and repeated efforts of this author, as also those of Poynton, an earlier worker along similar lines, to get recognition of the facts as we now know them.

Of the other relations existing between acute rheumatism and endocarditis there is little or nothing to add to the facts as established many years ago. It is a little humiliating, for example, to read again the conclusions drawn by Church just forty years ago from his examination of 700 cases of the disease, an analysis which is still quoted in the manuals. True, his estimate that only one-half of the patients affected had some heart affection in their first attack has been considered too low, as seen by my reference to the views of his colleague Norman Moore; but Church's other conclusions have received confirmation down to the present day. For example, he said that the heart, when affected, is usually implicated during the first week of the attack; that the liability to cardiac involvement diminished with age; that no system of treatment, whether by drugs or otherwise, had until then been shown to influence the tendency to endocarditis in acute rheumatism; that relief from pain and fever occurred four or five days sooner in patients treated by salicylates than in those not so treated. It is doubtful if an analysis of the last 700 consecutive cases of acute rheumatism at the same hospital would lead to any different conclusions. Some things, however, which mere statistics could not convey, would, I think, strike the thoughtful investigator, if he took the trouble to study the individual records rather than merely to catalogue the main results.

GROWING INFREQUENCY OF RHEUMATIC FEVER.

There seems little doubt that cases of severe acute endocarditis during the first attack of the disease are less common than formerly. Further, and perhaps explaining the fact, rheumatic fever in the severe form which was so common even twenty-five years ago is not at all a common disease to-day. Is it not rather uncommon to see a young man, either in hospital or in private practice, presenting the picture of severe rheumatic fever? Yet such cases were an almost daily experience a generation ago. The hyperpyrexial form of the disease, and cases in which cerebral symptoms were a striking feature, seem entirely to have disappeared. Church, in the analysis just quoted, refers to the fact that already both pericarditis and lung complications had even at that time become much less frequent, and he adds with caution that it remained to be proved whether this was due to salicylate treatment or to other causes. After forty years I fear that we must add that we still do not know. May it not have been even then due to some change in the interaction between the virus and the tissues resulting from a change in the virulence of the infecting agent; or to some change in the resistance of the tissues infected? And may not the continued tendency, since Church's analysis was made, for pericarditis, and especially pericarditis with liquid effusion, to become less common, together with the lessened severity of the cases of acute endocarditis, and of rheumatic fever generally, be expressions of one or both of these same changes?

Following the line of thought introduced by Swift, who refers to two distinct types of response on the part of the tissues to infection by rheumatic fever—the proliferative and the exudative—we should say that the facts just mentioned suggest that exudative changes have become less common, whereas proliferative changes have remained as frequent as before, or have perhaps tended to increase in frequency. I shall refer again later to the relative infrequency of a first attack of acute rheumatic endocarditis in young adults. The possibility of a more complete resolution taking place in a valvulitis at this age, provided no further infection takes place, than in children, in whom the valve cusps are exceedingly thin and delicate, must not be overlooked.

But with this change in the character of the disease we call acute rheumatism or rheumatic fever, so that its more severe forms and the coincident forms of acute endocarditis and pericardial effusion have become much less common, there has probably occurred an increased frequency of the subacute and chronic forms of the infection, together with subacute and chronic endocarditis. I have not the benefit

of a large experience at a children's hospital, yet I gather that this statement applies equally to children as to adults. It is constantly noted by those who see many ill children that rheumatic heart disease frequently arises in the absence of arthritic signs or indeed of any signs other than those indicative of the carditis. Although this fact was well known to physicians forty years ago, the number of cases of rheumatic heart disease found in children who present no other feature seems now to bear a larger percentage to the whole than formerly.

RESIDUAL VALVE CHANGES.

Let me turn now to a consideration of the types of endocardial lesions which result from rheumatic infection, whether acute, subacute, or chronic. In the first place, let me trace the course of a mitral endocarditis set up during an attack of rheumatic fever as closely as the known facts will allow. Since we must regard the inflammation as being essentially a valvulitis—a point emphasized by Swift in his recent studies—it is difficult to see how complete resolution can take place in so delicate a structure once it has been inflamed in the particular manner we know to be characteristic of rheumatism. It is probable, therefore, that few if any cases escape some degree of resultant injury. It is also probable that the conservative estimates of the earlier observers, such as Church, relative to the frequency of involvement of the heart valves in rheumatism, and also of the proportion of complete recoveries, are explained by the fact that the estimates were made at too short a period of observation after the attack. It was known that the systolic bruit so frequently present during the attack not infrequently disappeared for a time, and then reappeared; but it is likely that many cases, and especially hospital cases—upon which, almost entirely, statistics are based—were registered as being free from valve mischief during this very interval when there were no signs of heart disease. Kemp, as the result of a careful analysis of cases of acute rheumatism in the Radcliffe Infirmary, concludes that these older estimates of the incidence of heart affections, and of subsequent damage, were correct. He also concludes that much that was termed endocarditis in acute rheumatism was really myocarditis, and largely recoverable.

What were the recognized results of the valvulitis caused by acute rheumatism other than the hypothetical recoveries? They were three. (1) Cicatrization takes place, leaving the valve cusps deformed and shrunken, but eventually settling down into permanent shape and remaining so for a long time, it may be many years, until some other factors come into play to disturb the compensating mechanism in the heart. To this condition the term "mitral incompetence" was given. (2) Further and frequent attacks of rheumatic infection may enhance the damage and increase the valvular defect. The resultant state of the mitral orifice imposes more difficulty upon the circulation, embarrassed further by associated changes in the mural endocardium, in the myocardium, and perhaps also in the pericardium, attendant upon the repeated invasions of the virus. The net result of this recurring type of acute rheumatism was the production of what was termed "double mitral disease." (3) The third alternative sequel was the gradual, or rarely the rapid, transition of the case into one of the ulcerating type of endocarditis. Of this sequence more anon.

What was the recognized result upon the mitral valve of rheumatic infection with more insidious and more chronic symptoms—"growing pains," mild chorea, myalgia, and various fibrositic manifestations? Although it was believed that many of the cases in this group might develop mitral incompetence with or without stenosis, there was a general belief that the net result was likely to be the production of mitral stenosis, with little or no regurgitation. I speak here of tendencies and of average results merely, not of absolute or universal findings. The more purely regurgitant a mitral lesion was found to be the more likely was it that the patient had had an acute attack of rheumatism and one attack only, or, if more than one attack, then with intervals of some years between the attacks. The more purely stenotic the mitral lesion was found to be, the more likely was it that the patient had

never had an attack of acute rheumatism, but had had some mild rheumatic manifestations of the chronic kind just mentioned, or gave no history of any rheumatism at all. Looked at from another angle, the type case of mitral incompetence was an adult man who had had a severe but single attack of acute rheumatism in his teens. The type case of double mitral disease was a child or young adult who owed the defect to repeated attacks of rheumatism, largely subacute, and who had considerable myocardial damage in addition. The type case of mitral stenosis was a middle-aged woman, who rarely gave a history of acute rheumatism, and often gave no history of rheumatism at all.

How do these views compare with current ideas as to the resultant valve changes following rheumatic infection? There has been of late years a tendency to consider mitral incompetence a very uncommon sequel to acute rheumatism; indeed, many cardiologists of the present day have discarded the term altogether, or use it only to signify patency of the mitral orifice resulting from cardiac dilatation, temporary or permanent. When faced with a patient who presents signs of what others would term cardiac hypertrophy with a blowing systolic bruit transmitted to the axilla and a diastolic interval free from both bruit and thrill, they explain the state of affairs by postulating a diseased myocardium and a dilated mitral ring; and when dilatation of the heart arrives in such a case they read this to be due to failure of the myocardium originally and permanently damaged by rheumatism rather than due to inability of the hypertrophied ventricle to compensate further for the regurgitation. Others wander still further from the old conception, and, feeling so certain that the end-result of rheumatic mitral valvulitis is more or less of mitral stenosis, they actually apply this latter term to cases presenting the signs just mentioned. So the apparent anomaly arises, that of two physicians who examine the same case, one will label it "mitral incompetence" and the other "mitral stenosis." All this is much to the confusion of the student's mind. Without, as yet, the help of proper figures to guide me, I think it is true to say that *post-mortem* experience favours the view that mitral incompetence due to old rheumatic endocarditis is much less common to-day than formerly.

It is not so very important that such a paradox arises as it is that the circumstance denotes very definitely a changed conception in the rheumatic process. The change is far-reaching in its effect upon our attitude towards post-rheumatic hearts; it is only as yet partly reflected in the textbooks and in the routine teaching of the schools. It is, I think, of more than academic interest to inquire if this change be due to more careful and more prolonged observations carried out upon hearts affected by rheumatism or to an actual change in the material observed. That our predecessors were not less skilled than we are with their hands and ears scarcely admits of doubt; and certainly they gave as much time to thought on all these matters. Moreover, be it noted, the particular point is not one upon which either x rays or instrumental methods have thrown much light. It is, however, possible that the opportunity for prolonged observations upon large numbers of cases of heart disease has been greater during the post-war period.

I am as yet uncertain which of the two explanations I have offered for this change of attitude is the correct one, or whether it be each explanation in part. Auricular fibrillation has been the subject of so much attention of late years, and is so intimately bound up with heart failure in mitral stenosis, that there is possibly an added factor here in concentrating the mind upon this particular condition. Put briefly, the changed conception resolves itself into this—that very much of the life-history of the rheumatic heart may be expressed by the term "chronic rheumatic valvulitis." There certainly seems much reason in disallowing that the progressive sclerosis which goes on in the mitral cusps and adjacent endocardium, up to the production of the "button-hole" mitral orifice, is merely a slow residual contraction after an initial injury. That some chronic and persistent irritant is still at work through long periods of time seems certain. But is that irritant the rheumatic virus?

THE PROBLEM OF MITRAL STENOSIS.

The occurrence of "pure mitral stenosis" in women who give no history of any illness prior to the development of cardiac symptoms has always been a puzzling fact, and remains so to-day. An analysis of the last 100 cases of pure mitral stenosis admitted to St. Bartholomew's Hospital shows that 76 were females and 24 were males. In 63 out of the 100 cases there was no history of acute rheumatism, and in 36 out of the 100 cases there was no history of rheumatism or of any allied condition. Of these 36 cases, 27 were women and 9 were men. In a careful analysis of 50 cases of mitral stenosis in soldiers Cotton found a history of acute rheumatism in 22 only. French observers have considered that the condition is a congenital one—that is to say, that it begins as a congenital defect, and that this increases as time goes on. Dieulafoy, commenting upon the frequency of, and the unique features presented by, this form of valvular disease, says, "It is sometimes associated with congenital malformations" (but he does not cite instances of this). "It is independent of rheumatism and the other causes which usually give rise to endocarditis. This stenosis is associated sometimes with chlorosis." But we in Great Britain do not seem to have found this association any more than we have found Virchow's hypoplasia of the aorta in this connexion. There has been an effort made by other French observers to associate mitral stenosis with tuberculosis, not so much directly as indirectly, through tuberculous toxins. But this view, again, lacks confirmation. Poynton drew attention to the constancy with which renal sclerosis was found *post mortem* in association with these cases of advanced mitral stenosis, and it is interesting to reflect that it is in the same sex, and about the same age, that another mysterious sclerosing lesion appears in type form—namely, the so-called "contracting white kidney." Until we know more of the specific cause of rheumatism we do not seem likely to get nearer to the solution of the problem of this special form of mitral sclerosis. At present it is impossible either to assert or deny that these cases are the result of the specific action of the rheumatic virus. The fact that the specific histological lesion of rheumatism is not found in them certainly must not be taken as excluding the possibility of their being rheumatic, for the chronicity of the process, and the fibroid nature of the changes in the valve segments, would, by analogy with other chronic infections, explain this fact. We do not (readily) find gummatous formations in parasymphilitic diseases, nor tubercles in fibroid types of tuberculosis. Moreover, it is not easy always to demonstrate Aschoff's nodes in some cases of carditis in which, on all other grounds, we have no reasonable doubt that the infection is rheumatic. Whatever the etiology of mitral stenosis in its extreme form in adults may be, it seems certain that the proportionate incidence of chronic sclerosing endocarditis is greater than it formerly was. It is tempting to associate this fact with that other fact to which I have referred—the decline in the incidence of severe acute rheumatism and a relative increase in mild and recurring cases.

Of the endocarditis occurring in scarlet fever I will only say this—that there seems to be a proportionately greater tendency for aortic involvement than in the case of acute rheumatism, a point to which I shall refer again.

SYPHILIS OF THE ENDOCARDIUM.

The affections of the endocardium due to syphilis are probably less difficult to define than in the case of rheumatism. We know that the part most often affected is that of the aortic cusps, and we also know that such affection is in most cases part of an aortitis. Syphilitic disease of the aortic cusps leaves these delicate structures fibrosed and contracted, leading to aortic incompetence and its various sequelae. Rheumatism affects the mitral much more often than the aortic cusps, and probably affects the aortic cusps alone quite rarely. The converse is the case with syphilis. It is generally held that the mitral cusps are not affected at all by syphilis, but I have been struck by the not infrequent presence of a well marked apical systolic bruit in cases of parasymphilitic disease of the central nervous system, and in the absence of any history of

rheumatism. The bruit has been musical in character in some cases—a feature which makes it unlikely that the murmur has been due to mere dilatation of the mitral ring. I am not here referring to cases in which aortic disease is present, and in which, therefore, there might be secondary changes at the mitral orifice.

We owe to Warthin a very complete investigation into the changes induced in the heart and aorta by syphilis. Warthin's studies make it clear that these changes are both diffuse and focal, and we cannot but be struck by the resemblance in many points between the mode of attack of syphilis and of rheumatism. In both infections there are produced proliferative lesions, largely perivascular in nature, with nodal structures which are recognizable histologically. There is some not distant resemblance between these nodal lesions in the two diseases, so that it is a little strange that the likeness between the Aschoff bodies in rheumatism and the small gummata in syphilis of the heart has not led observers to consider if the virus of acute rheumatism may not be spirochaetal in nature. Warthin and others have pointed out that the *Treponema pallidum* is sometimes demonstrated in large numbers in the myocardium, even when there are none to be found elsewhere in the body. So far as the endocardium is concerned the typical lesion of syphilis is undoubtedly a mesoarteritis affecting chiefly the base of the aorta, which includes the sinuses of Valsalva, the roots of the aortic cusps, and the part of the aorta just above these structures. No doubt in many instances the process includes a true aortic valvulitis. The disease is prone to be very latent, so that our evidence of its actual incidence, in terms of frequency, can only be assessed indirectly. The sources of this indirect evidence are three. (1) Patients occasionally come under observation with symptoms which render a diagnosis of syphilis of the aortic ring extremely probable, and they respond well to antisyphilitic treatment. I shall return to these later. (2) Aortic incompetence in men about the age of 40, who give no history of acute rheumatism, or of any other infective process likely to cause endocarditis, and whose blood gives a positive complement fixation test for syphilis, is quite common. We seem justified in regarding these cases as residual after old syphilitic disease of the aortic cusps, or indeed as being still the subjects of aortic syphilis. (3) In the post-mortem room we frequently come across undoubted evidence of syphilitic disease of this region of the aorta which has not been suspected during life. This may be because death has been sudden or because the actual damage to the aortic cusps has not been so severe or so prolonged as to lead to symptoms. The extreme latency which is so marked a feature in syphilitic disease of the aorta was strikingly illustrated in the case of a policeman admitted to St. Bartholomew's Hospital.

His age was 32 years. His history was to the effect that whilst assisting a fellow constable to lift a corpse down a flight of stairs his companion, who went before, slipped on a step and fell. The patient, in order to save himself from falling also, leant back heavily, still holding on to the dead body. At the moment that he did this he felt a sharp pain in his chest and became faint. He was assisted downstairs and to the open air, sat down, and soon felt better. However, he was sent home, and, still feeling queer, he went to bed. His wife, who was out at the time of his arrival, returned and brought him some tea. As he was taking this he saw his wife looking about the bedroom as though searching for something, and on his inquiring what it was, "I was looking for the cat," she replied. She then explained to him that she could hear the cat purring. However, no cat could be found, and the woman discovered to her surprise, on approaching the bed more closely, that the purr proceeded from her husband's chest. The pain from which the patient at first suffered had gone completely in three or four days; he was kept in bed for ten days, and then sent by ambulance to hospital. When seen, the bruit was still very loud, and could be heard distinctly by leaning over the bed, it being not necessary for the observer's head to touch the chest wall. The murmur was highly musical in character and was diastolic in time. There was no evidence of cardiac hypertrophy, but there were the usual arterial signs of aortic regurgitation. A fairly marked anaemia was present and a "triple plus" Wassermann reaction. There was a history of syphilitic infection ten years previously. The patient improved rapidly under treatment by potassium iodide and mercury, and left the hospital well, but with the signs of aortic regurgitation. There can scarcely be much doubt that this was a case of rupture of an aortic cusp already the site of a syphilitic valvulitis.

All this indirect evidence, taken together, makes it certain that syphilitic aortitis, with aortic valvulitis, is a

not uncommon disease. It is obviously very important that we should bear this fact in mind in our practice, and be prepared to suspect the disease, even though, as I shall now proceed to show, our means of diagnosing it with certainty are slender. If we wait until gross structural changes are produced in the aortic cusps we wait too long. It is to be doubted whether, in syphilis, as in acute rheumatism, complete resolution can ever take place once valvulitis has been present. But by checking, or by stopping altogether, the process of active infiltration and proliferation in the valve cusps, we can lessen the residual damage in these structures, and thus prolong considerably the period of relative cardiac sufficiency which every case of aortic incompetence can only at best enjoy. No doubt a part of this increased freedom from undesirable sequelae is due here, as it is in rheumatism in similar circumstances, to the fact that the myocardium has been protected from gross damage.

AGE-INCIDENCE OF AORTIC SYPHILIS.

An important question arises: At about what interval after the primary infection does syphilitic disease of the aorta begin? At about what age shall we begin to consider the possible presence of the disease? In treating quite recently of a series of cases of cardiac syphilis Carey Combs computes that the period between infection and the onset of the symptoms was over twenty years; he gives the average age of his patients as 53. Combs does not distinguish between the cases showing evidence of aortic disease and those whose main defect happened to be myocardial, and it may perhaps be assumed that such distinction would have affected these figures. As the result of a still larger number of cases studied by him, Strickland Goodall has recently put the period elapsing between the primary infection and the appearance of symptoms even higher than this. Although I am unable to give statistics, I am led to the view from my own experience that these figures give no true expression of the early cases of the disease. It is notoriously difficult to differentiate between the fibrotic residues of old inflammation and the lesions of still active disease; no more common problem arises in the post-mortem room than the proper interpretation of the changes frequently seen in the aorta. And no less difficulty arises in regard to the interpretation of symptoms during life: are they due to active disease or to atheromatous changes in the production of which syphilis is only one causative factor? If we follow the view that smouldering infection still remains in all cases in which there is to be obtained a positive complement fixation test, this makes it more, and not less, likely that the first invasion of the tissues by the *Treponema pallidum* takes place much earlier than signs or even symptoms show themselves.

Is it not probable that the known facts in regard to that other distinctive and equally common syphilitic arterial disease, cerebral arteritis, give us some guide in this connexion? Unless we have some reason for taking a different view it is at least likely that the time of incidence in the course of syphilis of arteritis in the branches of the circle of Willis approximates to the time of incidence of syphilis of the aorta and the aortic cusps. And the former we have fairly good evidence for placing at from five to ten years after the primary infection. The difference in the age incidence when calculated from a large series of cases would be explained by the fact that syphilis of the cerebral arteries can scarcely remain long without symptoms, whereas syphilis of the aorta can, and frequently does. Perhaps this matter may be stated most clearly by postulating two somewhat different types of lesion produced by syphilis in the aorta, as there are two somewhat different types of lesion in the central nervous system. There is an earlier lesion, of the gummatous kind, largely proliferative in character and possessed of focal lesions in a high degree, and a later type of lesion, largely fibrotic in its features, to which the term "para-syphilitic" may be not inappropriately applied. If this conception be admissible then the apparent discrepancy to which I have referred would be explained. So also would be explained, and rendered again analogous, the known lack of effective response to antisyphilitic treatment in cases of syphilitic aortitis when once the signs of aortic

incompetence are present. No doubt both types of lesion may be present at the same time—a fact which accounts in part for the great difficulty often experienced in the interpretation of *post-mortem* findings. If this view be substantially correct it becomes a still more urgent matter to track down the early cases by all means in our power. We must look for these cases in men (by preference) who are between the ages of 25 and 40.

SYMPTOMS OF AORTIC SYPHILIS.

The main—and in perhaps most of the cases the only—symptom is pain, anginoid in character, situated in the region of the sternum rather than in the region of the precordium, with a zone of reference or spread less extensive than is usual in angina pectoris. The pain is usually induced by, or increased with, effort, but this feature is not constant. Shortness of breath and the effort syndrome are sometimes present, but when this is so it is probable, from our general knowledge of these symptoms, that there is myocardial disease in addition to, or rather than, aortitis. There may be complaint of more general symptoms, such as slackness and vague dyspeptic symptoms, and the patient may be anaemic. But since these latter symptoms are common to so many diseases it remains that it is the pain, and the pain alone, which arouses our suspicions in most of the cases.

As regards physical signs, these are absent or are equivocal. Lack of clearness in the aortic second sound, whether directly over the valve or at any point where the aortic second sound is listened to critically—and this should include the region just above the xiphisternum—is very suspicious. A ringing character to this sound, in the absence of high arterial tension, is perhaps equally significant. More change than one of these—to wit, a definite diastolic bruit—probably means that the valvulitis is not early, and that resolution will not occur completely with treatment. I have only once, in a case of syphilitic aortitis, heard a definite diastolic bruit which disappeared with antisyphilitic treatment. It returned some two years later, despite continued treatment, and the patient then developed the arterial signs of aortic regurgitation. It is to be inferred that the disease was not detected at a sufficiently early stage to avert cicatricial changes. It is perhaps doubtful if we could ever completely avert some degree of cicatricial changes if a syphilitic valvulitis were once established, any more than we can in a rheumatic valvulitis, even though our means of treatment are much more "specific." The disappearance of the bruit and its reappearance later in permanent fashion is very reminiscent of what we know to happen not infrequently in the case of rheumatic fever.

I have never satisfied myself that the disease in its curable stage yields demonstrable dilatation of the aorta by physical signs. Nor have I ever got this evidence from x-ray examination, though I understand that Price has met with a different experience. Our French colleagues construct a more elaborate picture of the signs and symptoms of early degrees of aortitis, but I find it difficult to follow them in actual practice. I doubt if at present we can go further than to say that a man below the age of 50, whose arterial tension is not raised, whose blood gives a positive complement fixation for syphilis, and who complains of pain that may reasonably be attributed to the aorta, is probably suffering from syphilitic disease of this structure. If his age be under 40 the diagnosis is less uncertain. Treatment should be carried out promptly and thoroughly, and, since it is held strongly by some high authorities that active syphilitic infection should be presumed so long as the complement fixation test remains positive, here, at least, this doctrine should determine our action, since there is so much to gain if it be true, and so little to lose if it be false. The important points are these: first, that it may be possible to detect and to treat syphilitic aortitis before the aortic cusps are involved; and secondly, that if it be detected and treated while as yet the degree of valvulitis is slight, the resultant valve damage may be so little, and so unprogressive, as not to prejudice the patient for an indefinite number of years.

OBSERVATIONS ON THE FRONTAL SINUS.

BY

WILLIAM OLIVER LODGE, M.D., F.R.C.S.ED.,
D.O.M.S.ENG.,

OPHTHALMIC SURGEON, BRADFORD MUNICIPAL GENERAL HOSPITAL, ETC.

CATARRHAL INFLAMMATION.

It is during quiet intervals that the diagnosis of the milder forms of recurrent catarrhal inflammation of the frontal sinus presents most difficulty. Deep tenderness may be elicited, but the floor of the sinus is a tender spot in most individuals. Often the nasal chambers appear healthy; transillumination is of no help, and the radiographer makes a negative report. Everything depends on a reliable account of the symptoms. The following case exemplifies this common type.

CASE I.

A woman, aged 41, complained of intermittent aching and feeling of congestion in the frontal region. During the attacks, which recurred at varying intervals, usually after a cold in the head, and lasted for a few days, the timbre of the voice was slightly altered. Six months previously, after confinement to bed for a week owing to severe frontal pain on the left side, there was a sudden escape of slimy fluid into the nose, with immediate relief.

Pain was elicited on pressing upwards on the roof of the orbit on both sides. There was a little mucoid secretion in the nasal vestibule, but none in the middle meatus on either side. Prominent opercula did not permit of the passage of a probe up the fronto-nasal ducts. On radiographic examination the paranasal sinuses were reported normal. The patient preferred to await further developments before resorting to any form of operative investigation or treatment.

The early and continued use of a nasal spray containing menthol, chlorotone, etc., in an oily base sometimes wards off an attack. During an attack the introduction of a pledget of cotton-wool moistened with cocaine and adrenaline solution beneath the middle turbinal may give relief. Resection of the anterior portion of the middle turbinated bone, with or without probing and dilatation of the duct, yields more consistently satisfactory results; but to persuade patients during a quiet interval to submit to operation would in most cases entail an unjustifiable promise of cure without risk.

MUCOCELE.

Mucocele is less frequent in the frontal than in other accessory sinuses. The first complaint is generally of pain, or of some visual disturbance, such as epiphora, diplopia, or proptosis. The conditions which would appear to favour the development of mucocele are closure of the outlet, which may be partial or intermittent, and absence of pyogenic organisms. The walls are expanded or a breach is made and an external swelling forms. Pressure over the swelling may cause some of the thick glairy green contents to trickle into the nose. The obstruction may be developmental, but a variety of causes, among them osteoma of the frontal sinus, have been recorded. In the following case, associated with polypoid disease, the walls of the sinus were much expanded but still intact at the time of operation.

CASE II.

A man, aged 30, complained of a swelling which was becoming increasingly prominent in the right supraorbital region, of nasal obstruction of some years' duration, which was now complete on the right side, of a sense of heaviness about the eyes, and of frontal headache.

The swelling, which was smooth and round, occupied the space between the inner canthus, the superciliary ridge, supraorbital notch, and root of the nose. It was firm to the touch, and merged imperceptibly into the adjacent surfaces. The nasal obstruction was due to polypi, which blocked the right side of the nose completely and obstructed the left side to a minor degree. A skiagram showed spacious paranasal sinuses, the shadows of which were clear (especially that of the right frontal sinus), except that there was some degree of "veiling" of the shadow of the right antrum.

Operation.—Under general anaesthesia, administered through Kuhn's tube, a curved incision was made along the inner third of the superior orbital margin and continued downwards to the inferior orbital margin. The lacrimal sac was displaced from its groove, and, commencing just above this point, the bone was removed from the outer wall of the nose and inner part of the floor of the sinus. On incising the mucous membrane the infundibulum was found to be packed with polypi. The sinus itself was filled with greenish viscid fluid of unpleasant

odour. The opening was enlarged, without disturbing the trochlear attachment of the superior oblique muscle or removing much of the supraorbital plate. Working partly through the nose and partly through the incision, the middle turbinal and ethmoidal cells were removed. A flap of mucous membrane preserved for the purpose was turned outwards to cover the floor of the wide passage which now connected the frontal sinus with the nose. The skin incision was closed. The maxillary antrum was explored, but no fluid was found.

Healing was rapid and free from complications. A fortnight later polypi were removed from the left side of the nose under cocaine anaesthesia. There appeared to be no indication for further operative measures.

PURULENT INFLAMMATION.

Empyema of the frontal sinus is due to ascending infection from the nose. This may be secondary to trauma, or to a great variety of other causes, of which influenza, foreign bodies or insects in the nose, and ethmoid suppuration are examples. Empyema may be acute or chronic, and is sometimes described as open, intermittent, or closed, according to the state of the fronto-nasal duct. Pressure on the walls of the sinus may cause necrosis. The worst cases are those in which the symptoms are latent, as in brain abscess, and the empyema is part of an osteomyelitis of the frontal bone.

CASE III.

A youth, aged 18, was kicked on the head whilst playing football and sustained slight concussion. There was neither bruising nor bleeding from the nose. He gradually became

FIG. 1.—Case IV. Tracing from skiagram of nasal accessory sinuses before the insertion of the tube. Opaque areas shaded.

FIG. 2.—Case IV. Actual size of the tube.

FIG. 3.—Case IV. Left frontal sinus drained by a silver tube clear of the maxillary antrum, into which discharges were previously finding their way.

FIG. 4.—Case V. Appearance with rubber drain in position on left side. There is a silver tube in the right infundibulum.

trowsy and strange in manner, and complained of generalized headache. Finally a swelling appeared on the forehead, and rigors occurred. The patient came under my care a month after the original injury. The pulse rate was 84, temperature 99.8° F., respirations 24. In the right supraorbital region was a swelling, which pitted on pressure—a typical Pott's puffy tumour. The lids were swollen and the conjunctiva chemosed. Palpation of these parts caused pain all over the head. There was commencing papilloedema on both sides. Pus was visible in the middle nasal meatus on the right side.

Operation.—On exposing the right side of the frontal bone pus exuded from minute apertures in the outer table. No fracture was visible. The frontal sinuses were full of pus, and far beyond the area of most acute osteomyelitis the diploë presented an appearance of dry gangrene. There was a thin layer of pus beneath the bone. On incising the dura localized purulent leptomeningitis was found. Haemostasis was secured, and a dressing was applied. The patient rallied after the operation, but died on the following day.

The next case to be recorded was less acute, and the patient recovered.

CASE IV.

A nurse, convalescent from influenza, complained of lancinating supraorbital pain, radiating to the back of the head. An inflammatory swelling developed beneath the left upper eyelid, causing ptosis and downward displacement of the eyeball. On rhinoscopy the anterior end of the left middle turbinal and ethmoidal bulla appeared swollen, but no pus was visible. The temperature was normal, the pulse rate 108. On incising the swelling pus welled into the wound from an aperture in the supraorbital plate. *Staphylococci* were cultivated from this.

Operation.—Killian's operation was carried out. Parts of the sinus walls were eroded, and granulations in the infundibulum bled freely; consequently, after removal of the frontal process of the superior maxilla, a satisfactory flap of mucous membrane to cover the surfaces facing the nasal cavity was not obtained. The middle turbinal and ethmoid cells were completely excised, but the uncinate process was left intact.

After-treatment.—All went well until the thirty-fourth day, when the opening into the nose became blocked with exuberant granulations, the lids swelled, and there was local pain and throbbing. A fistula at the outer angle of the wound discharged

periodically. An attempt was made to clear the passage, but without lasting benefit. A suspicion that pus might be flowing into the antrum instead of into the nose was confirmed by a skiagram, which showed that the greater part of the left maxillary antrum was opaque. The wound was reopened, and a silver tube was placed in position to secure drainage into the floor of the nose. The whole condition promptly cleared up, and the patient was able to go home. The tube was withdrawn three months later.

Chronic purulent inflammation of the frontal sinus is much less frequent than the more acute forms. Pus is discharged into the nose or intermittently from an external fistula. One or two cases secondary to gunshot wounds have come under our observation. It is sometimes hard to say where deep-seated disease of the frontal bone will end.

CASE V.

A woman aged 24, one of whose brothers had died of tuberculosis, who was herself convalescent after influenza, complained of persistent fronto-occipital headaches. An operation was stated to have been performed on the turbinated bones and sphenoidal sinuses at this period. Two months later a swelling appeared in the forehead. The swelling was incised and the pus evacuated. A fistula remained which continued to discharge for the next three months.

On examination, six months after the onset of symptoms, which still continued, a discharging fistula was situated midway between the glabella and bregma. A probe inserted into the fistula passed directly backward for an inch and upward for an inch and a half. Bare bone could be felt inferiorly. The whole forehead was tender.

There were polypoid excrescences on the right middle turbinal, but no pus was visible in the nose. A probe could be passed into the infundibulum on the right side but not on the left. The optic discs were normal. There was slight flattening of the chest wall at the right apex, but no sign of active pulmonary disease. The Wassermann reaction was negative and remained so after a provocative injection of novarsenobillon. The von Pirquet test was negative.

The radiographer reported extensive erosion of almost the whole width of the frontal bone, which had not been evident at a previous examination made by him. He observed that the rapidity of progress did not suggest a tuberculous process.

Operation.—By means of a coronal incision within the hair line the integuments of the forehead were drawn down over the face. On enlarging the fistula a cavity an inch and a half in depth was discovered. This extradural abscess communicated by a track traversing the diploë of the frontal bone with the left frontal sinus. Sequestra were removed, and the carious anterior walls of both sinuses, which contained unhealthy granulations, were excised. At a later stage Killian's operation was completed on the left side, and by retracting the inner angle of the wound a silver drainage tube was inserted into the infundibulum of the right sinus. After a protracted convalescence the disease subsided.

The scars were mainly hidden by the hair. It can only be hoped that the disease is finally stamped out and will not recur as in the following inveterate case.

CASE VI.

A woman, aged 36, with scars over both frontal sinuses, complained of recurrent pain on the left side, where a fluctuating swelling was evident. She stated that since the age of 12, when the swelling at the root of the nose (shown in the photograph, which she permitted me to have copied) first developed, she had undergone a dozen operations on the frontal sinuses.

The odour seeming inauspicious, nothing further was done save the introduction of a tube through dense fibrous tissue into the sinus. Later the patient was provided with a suitable bougie and instructed how to pass it daily into the sinus.

MISCELLANEOUS AFFECTIONS.

Tuberculosis of the frontal bone commencing in the diploë in children is characterized by the gradual produc-

tion of a discoid sequestrum with eroded edges. In gummatous periostitis more than one bone may be affected, as in the following case.

CASE VII.

A young man developed a brawny fluctuating swelling of the left upper eyelid, ptosis and downward displacement of the eyeball. A nodule was palpable over the right parietal eminence. Nothing abnormal was seen on rhinoscopy. Temperature 99° F., pulse 108. Recently there had been intense headaches culminating in brief periods of unconsciousness. No other relevant history was obtained, though it is perhaps proper to mention that sclero-corneal trephining operations for buphthalmos had been performed on both eyes.

X-ray examination showed periostitis of the frontal bone with absence or complete obliteration of the left frontal sinus. An exploratory incision revealed the state of affairs to which the small parietal nodule was the real clue. Intravenous treatment was commenced; the Wassermann reaction was strongly positive. The condition subsided under treatment.

A frontal swelling in infants may safely be assigned to causes other than sinusitis. Sarcoma by its rapid growth is apt to simulate an inflammatory condition. Osteoma of the sinus occasionally gives rise to inflammatory complications. If we except osteomata, metastases, and invasion of the sinus by rodent ulcer (only too readily recognized by the ghastly deformity and foul discharge), neoplasms of the frontal sinus are rare.

FIG. 5.—Case VI. Swelling at root of nose in a girl aged 12, due to bilateral frontal sinusitis.

FIG. 6.—Case VI. Patient preparatory to her thirteenth operation.

RADIOLOGY.

Skiagrams reveal the width, depth, and height of the sinuses. To this end antero-posterior, side-to-side, and stereoscopic projections may be studied. One frontal sinus may overlap its fellow of the opposite side, be traversed by incomplete septa, or be absent altogether. Alterations in contour from trauma or gross pathological changes may also be recognized. Forewarned, the operator proceeds with confidence and precision. It is when finer discrimination between normal and abnormal conditions is required that difficulty arises.

In the case of the frontal sinus the relative physicochemical density of the bones of the face must be measured. The presence or absence of air in the sinuses is immaterial. With tubes of the degree of penetration ordinarily used for the purpose, sinuses filled with polypi or cystic fluid may throw a normal shadow. Rarefaction and sclerosis of bone are slow processes. At the first suspicion of trouble the frontal sinuses may be reported normal, at a later stage "veiling" may be found. Conversely, a sinus commonly appears opaque after all symptoms have subsided. Before interpreting altered permeability of a sinus to x rays in clinical terms we should ask ourselves how the suspected condition is likely to affect the deposition of lime salts in the walls of the sinus, and whether it has had time to do so.

In two of the cases the maxillary antrum was more opaque although the primary seat of the disease was in the frontal sinus. In periostitis decalcified areas almost transparent in the x-ray film are sometimes only distinguishable from surrounding bone at operation by being slightly raised and scored with fine fissures. Naturally, values are different in photographs taken by means of rays whose waves are ten thousand times shorter than any with which the human eye is familiar.

CHOICE OF OPERATION.

Removal of the anterior portion of the middle turbinal often facilitates drainage, and it is possible in a proportion of cases to probe and dilate with graduated bougies the fronto-nasal duct. The intranasal use of rasps or trephines is apt to lead to subsequent stenosis.

When the walls of the sinus are intact an incision along the inner wall of the orbit permits of removal of the ethmoid cells and of lining the new passage to the frontal sinus with a broad mucous flap. When the sinus walls are diseased Killian's operation is called for. In osteomyelitis or necrosis of the frontal bone an incision from temple to temple within the hair line yields maximal access and minimal deformity, although a separate incision is required for removal of the ethmoid cells. In complicated cases—for example, when the frontal sinus drains into the maxillary antrum, or when bilateral suppuration exists and a radical operation on both sides is impracticable—good results may be obtained by drainage for three or four months with a silver tube.

These observations merely represent present practice in endeavouring to apply surgical principles to the problems presented.

CHRONIC PELVIC PAIN IN WOMEN.*

BY

ARNOLD ALCOCK, M.B., B.S. LOND.,

SURGEON TO THE GLOUCESTERSHIRE ROYAL INFIRMARY.

THE chief reason that prompts a woman to see her doctor is usually pain, either in the front or back of the pelvis. The pain is most frequently chronic. Acute pain is comparatively rare, and its origin much more easily determined. Like all other vague pain syndromes, these cases require a minute and painstaking examination, and a clear classification of the causes of pain in the lower part of the back must be kept in mind. The pain is either (1) nervous, (2) structural (skeletal or muscular), or (3) referred from a disorder of the internal organs.

THE NERVOUS SYSTEM.

To sift the cause of the pain the attitude of mind of the patient must be first elicited. The neurasthenic is a pitfall to many of us, but our suspicions that the case is one of the functional majority must only make our preliminary examination the more careful. Something very trivial may be wrong; I have actually had one patient who was reassured when told that it was natural for a froth to form on urine during micturition. Above all, remember that the suspected neurasthenic is in her own estimation suffering intensely.

The patient must be completely examined, and until then no hint must be given as to the possibility of the presence of appendicitis, displaced kidney or uterus, etc. A bimanual examination is essential, and if the patient be a married woman a satisfactory conclusion can usually be formed; but in the case of virgins a rectal examination is not as a rule very hopeful, and it is advisable to make the diagnosis sure by examining under an anaesthetic.

When it has been decided that there is no evidence of organic disease, the treatment is summed up in the words "assurance" and "reassurance." If the patient can be assured that she has no pelvic disease, a course of laxatives of the type of pil. aloes comp. (B.P.), together with a mixture containing potassium bromide, will frequently effect a cure. A suggestion from the examiner that she "may" develop appendicitis, or that the womb is slightly displaced, will upset the confidence of the patient, and lead her to seek further advice.

THE SKELETAL STRUCTURES.

The patient should be stripped in a good light and the spine examined in the erect posture, any limitation of movement being carefully noted. Any doubt as to the spine will be cleared up by an x-ray photograph. The sacro-iliac synchondroses must receive careful attention,

* Abstract of Presidential address to the Gloucestershire Branch of the British Medical Association

but early disease in this area is most difficult, if not impossible, to detect.

The diagnosis between early tuberculous disease of the spine and the so-called weak back is very difficult; but in the absence of x-ray evidence I pin my faith on limitation of movement.

Curves of the lumbar spine is not the only cause of a rigid spine; the conditions which must not be forgotten are (1) secondary carcinoma, usually associated with either a mammary or an ovarian tumour (possibly unsuspected), and (2) arthritis of the lumbar spine. In these conditions the skiagraphic appearances are definite. In the latter, tipping of the edges of the bodies of the vertebrae with osteophytic outgrowths are characteristic.

I believe that arthritis of the lumbar spine is quite a common cause of lumbo-sacral pain. This region is submitted to jars and sprains more than any other, and such parts are notoriously very susceptible to circulating toxins. Arthritis can be benefited considerably by systematic treatment. In the initial stages complete rest should be ordered, and much relief can be given by applying strapping round the pelvis. Later on exercises should be ordered, combined with massage and radiant heat. Spa treatment may be advised when it can be obtained. All possible sources of infection, such as septic teeth, tonsils, accessory sinuses, etc., having been eliminated, baths and washing the system out with the evil tasting and smelling waters of Harrogate, etc., will complete the elimination of toxins.

The Sacro-iliac Joints.

I have seen cases where the chronic lumbo-sacral pain has been referred to one or both of these joints, and I believe that, though tuberculosis is rare, arthritis frequently occurs. When one considers how commonly these structures are submitted to strain, especially in childbirth, this is not surprising, and pain in these regions coming after parturition should be adequately treated with absolute rest, to allow complete involution to take place. In an article on orthopaedics in gynaecology¹ Matthews states that subluxation of the sacro-iliac joint is one of the chief causes of backache. He says that reduction of the subluxation often gives immediate relief.

Paul Roth, speaking in a discussion on the diagnosis and treatment of affections of the sacro-iliac joints,² said that sacro-iliac strain had interested him for many years. He advocated manipulation and then support. Manipulation consisted in forcibly hyperextending the thigh on the trunk with the patient lying prone. I tried this treatment on a patient who was sent to me suffering from pain in the right iliac fossa, thought to be due to chronic appendicitis. The pain, in my opinion, was referred from the right sacro-iliac joint, and treatment as suggested by Mr. Roth effected an immediate cure. Dr. Mennell, in the same discussion, called attention to John Baer's sacro-iliac point, which is situated on a line from the umbilicus to the anterior superior spine, 2 inches from the former joint. He contrasted this with McBurney's point, and said that this explained the persistence of pain in the right iliac fossa after an appendix had been removed.

PAIN REFERRED FROM DISORDER OF INTERNAL ORGANS.

Pain from a disorder of the internal organs is due to two conditions: (a) tension within the muscular structures, and (b) dragging upon the mesentery. The viscera themselves have no sensation of pain; they can be cut, torn, and sutured without the production of pain. When they are irritated the pain will always be interpreted as coming from the peripheral distribution of the nerve fibres which are involved.

In the pelvis we are concerned with the organs associated with the segments of the cord below the eleventh dorsal—namely: (1) the large intestine and appendix, (2) the kidneys and bladder, (3) the uterus and appendages.

The Large Intestine.

The caecum and sigmoid are common sites for distension, and are either the cause or effect of chronic constipation in women. I am of the opinion that the condition is a defect in the neuro-muscular mechanism, as it is so frequently the result of overwork and worry. In normal

well developed women, constipation is never accompanied by chronic pain, but in those whose nervous systems are unstable, gurglings and discomforts in the right and left iliac fossae are gradually interpreted as pain.

The Appendix.

I wish to emphasize the statement that, if a woman complains of constant dragging or aching pain in the right iliac fossa, the cause of that pain is *never* the appendix. A needless operation for the removal of this organ brings discredit to the surgeon, and a continuance of its practice threatens the future confidence of the public in surgery.

While this was being written I saw three cases in one day in which an appendicectomy had been performed some few months previously for chronic pain in the right iliac fossa. The pain recurred as soon as the excitement of the operation had worn off, and, as is so often the case, a fresh opinion was sought—this, in one case, despite the fact that she had been told that her appendix was in "a shocking state." It is a pity surgeons do not always see and learn about their failures.

Appendicitis, either acute or chronic, does *not* give rise to persistent pain or aching in the right iliac fossa. In acute conditions the pain subsides entirely after a few days, and probably recurs later; and in the so-called chronic appendicitis—more correctly termed appendix dyspepsia—the symptoms are referred to the stomach and epigastrium, and rarely to McBurney's region. In one case that I operated upon I found the appendix bulbous and distended, and thought and hoped that the distension was the cause of the pain. Seen a month afterwards, the girl seemed to delight in saying to me, "I am feeling better, but the pain is still there." The subject of appendix dyspepsia is not relevant to this paper. Sir James Goodhart used to say, "God help a woman when she knows she has an ovary." I think the same can be applied to the womenfolk and the appendix.

The Kidneys and Bladder.

I will not weary you with a list of diseases of the urinary organs which may give rise to persistent pain in the pelvis, but will be content to describe the conditions which often cause women to present themselves at outpatient departments and elsewhere, complaining of pain in the iliac fossae, more commonly the right than the left. These are divided into two classes: (1) inflammatory, (2) excessive mobility.

Inflammation of the Kidneys.—Pyelitis is a common cause of chronic pain in the iliac regions, and many cases sent to me under suspicion of chronic appendicitis are found to be suffering from an infection of the kidney. The symptoms are frequency of micturition and mild persistent pain in the distribution of the twelfth dorsal nerve, accompanied by chilliness and mild shivering fits. Bacteriological examination of the urine often shows a pure culture of *Bacillus coli communis*. Palpation of the kidney will sometimes elicit tenderness, but the condition may be present without pain on pressure. A complete examination of a catheter specimen of urine is most important in the diagnosis of vague pelvic pains. The cure of these mild infections of the pelvis of the kidney is not easy. I find that an intensive course of potassium citrate in half-drachm doses combined with infusion of buchu is most beneficial if given for several weeks. Urinary antiseptics of the formaldehyde type are of little value in renal infections. The administration of drugs must be combined with liberal drinking of water and other innocuous fluids, and it is a question whether the abstinence from drinking, so common in young women, is not a large factor in the etiology of this complaint; and similarly the cure may be ascribed more to the mechanical flushing of the pelvis of the kidney than to drugs held in solution. The large intestine, as being the probable *fons et origo* of the condition, must be thoroughly cleared, and the inertia of its musculature stimulated by suitable measures.

Excessive Mobility.—In the large majority of cases of movable kidney the patient suffers from a dragging/aching pain in the lower abdomen and back. Such sensations are pain in the lower abdomen and back. Such sensations are usually constant when the patient is walking about, but subside after a few hours of recumbency. The chronic pain

is associated as a rule with digestive disturbances and nervous symptoms suggestive of neurasthenia. Pathological mobility must be distinguished from a mere palpable kidney, which occurs in 85 per cent. of normal women, but rarely in men. Acute attacks of renal colic—"paroxysms" as they have been termed—may supervene, and are the result of either kinking of the ureter with a transient hydronephrosis, or torsion of the pedicle with increased venous congestion of the kidney and increased intracapsular tension. The treatment of excessive mobility of the kidney is a severe strain on our professional patience and resourcefulness. I will tackle the question under (1) general tonic measures, (2) abdominal supports and trusses, and (3) surgical measures. Under (1) the first principle is to give the patient absolute rest for body and mind. She should be put to bed in bright surroundings and made to understand that she must lie altogether in the recumbent position. Diet should be liberal and all the ordinary laws of health and hygiene obeyed. After three weeks exercises should be commenced, helped, if practicable, by massage. The essence of treatment thereafter is to strengthen the muscles generally, and it is only with the cheerful co-operation of the patient that success can be obtained. The complaint is the result of "flabbiness" both of the muscular and nervous systems, and it is only cured by putting both into training, as an athlete would set about making himself fit to undergo the strains of a football or tennis season. (2) The only correct abdominal support is a well developed abdominal wall. A mechanical support can only lead to atrophy and weakness of the natural structures. Still, many women cannot develop their abdominal walls sufficiently to stand the strain of the erect posture—a condition not yet corrected by evolution, and comparable to varicose veins and piles. This being so, some cases are helped considerably by wearing a well fitting corset for general support. For the much vaunted kidney belts and trusses I have no use; in my experience they are usually discarded, as they give more pain than they relieve. (3) I hold the opinion that the only indications for operation in movable kidney are the recurrence of acute attacks of pain and vomiting, and the supervention of hydro-nephrosis or pyelitis.

The Bladder.—The constant pain associated with bladder lesions is felt behind the symphysis pubis. The distress is usually interrupted by paroxysmal attacks of pain occurring during micturition, either just before or at the termination of the act. The diagnosis is, as a rule, obvious.

The Uterus and Appendages.

Tumours of the pelvic organs, although they grow to such enormous dimensions, rarely give rise to chronic pain. The lesions which produce persistent discomfort are (1) inflammatory or haemorrhagic, and (2) mechanical—the former by producing tension, and the latter by dragging on the mesentery and fascial supports.

Chronic Endometritis and Chronic Metritis.—In *Diseases of Women*, by Ten Teachers, the pathology of these conditions is clearly discussed, and it is stated that there is clear proof of the inflammatory nature of both these conditions. The former, endometritis, is either a disease *per se*, or, if not cured, is the first stage of the latter. Chronic pain in the back in the sacral area is associated with menorrhagia and leucorrhoea. Menstruation is prolonged and profuse, and there may be slight intermenstrual haemorrhage suggestive of the presence of a malignant growth. Early cases may be cured by promoting an improvement in the general health, and benefit is undoubtedly obtained from ergot and calcium lactate. I might mention also the improvement noticed after intramuscular injection of colloidal calcium. If good result does not follow medical treatment, curettage must be advised without delay. It has been said that the sharp curette should only be seen in a museum of antiquities: I do not agree. Early cases of endometritis can be cured by curettage, but this must be performed thoroughly, carefully, and, above all, aseptically. If no relief follows, and the microscopical report of the endometrium negatives any idea of malignancy, chronic metritis has probably supervened.

Fibrosis uteri (or bleeding uterus, as it is also called) is common after the age of 40, and from the continued

haemorrhage and chronic pain is productive of much suffering. On examination very little abnormal can be felt, for frequently the uterus is not even enlarged. Curettage is useless as a mode of treatment in this condition, and I have no hesitation in advising hysterectomy with conservation of the ovaries. The entirely successful results, with freedom from anxiety as to the future, which hysterectomy offers in this condition, make me hesitate to advise the doubtful benefits of radium or x-ray therapy.

Chronic Salpingitis.—Here the Fallopian tubes are thickened, and, as a result of the closure of the fimbriated extremities, become distended. The surrounding structures are matted together by the inflammatory exudate. The pain is situated in the lower lumbar region and is of a gnawing character. In the treatment of this disease I wish to lay stress on the value of conservatism. It is a proved fact that in these cases of chronic pelvic peritonitis the bacteria will die off and the inflammation will undergo absorption. Complete rest in bed, with hot packs and douches to relieve pain, for several weeks is essential. Should abscess formation occur I strongly advise vaginal as against abdominal drainage.

Pelvic Haematocoele.—I mention this condition briefly as causing similar symptoms. The slow leaking of blood into the pelvis is due either to a ruptured tubal pregnancy or to bleeding from a ruptured lutein cyst in the ovary. I emphasize the latter condition, as on three occasions I have found blood in the pelvis which was the result of ovarian bleeding and unconnected with pregnancy.

Retroversion.—This is a bone of contention to the gynaecologists. Personally, I am very doubtful if a retroverted uterus ever gives rise to pain. I am confident that an organ three and a half inches long and freely movable does not cause symptoms. If it is enlarged, and so being under tension, it will give pain, but then the concomitant endometritis or metritis is the prime factor. The hyperplasia can be cured and the patient relieved without correcting the retroversion. Similarly, descent of the uterus always causes a certain degree of retroversion, and it is the prime factor in giving rise to pelvic pain. Most cases of retroversion do not require any treatment. If pain in the back is complained of and a retroverted uterus is discovered, another cause must be sought for the pain, and, as is so important with most displaced organs, no mention of it should be made to the patient, but a near relative may be told that the fact is recognized. If correction is deemed advisable, this can be done by bimanual manipulation and the insertion of a ring pessary to prevent the uterus from falling back again. A Hodge or other hard pessary is harmful, and not so efficient as a soft rubber ring, which in any case can do no harm. At the British Medical Association meeting at Bath, Dr. Russell Andrews gave as his opinion that the only absolute indications for operative treatment were sterility, dyspareunia, and prolapse. The first two are rare, and the subjects are often willing to have an operation as a speculative measure, and the third comes under another heading altogether. The procedure recommended is Mayo's modification of Gilliam's operation. The idea of suspension is correct in theory, but often useless in practice. Ventrofixation has had its day—it is unsound in theory, and so liable to be followed by complications that it can be regarded as dangerous in practice.

Prolapse of the Pelvic Organs.

Descent of the pelvic organs, and the resultant dragging on the peritoneal attachments and fascial supports, is the most frequently found cause of lasting pelvic pain. The perineum has been expressively termed "the inferior abdominal wall," and certainly what we understand as prolapse is a hernial protrusion through this structure; and I believe that the weakening of the muscular and fascial layers which constitute it is the first principle in the production of prolapse. If the wall is torn or lacks tone, only a slight increase of intra-abdominal tension is necessary to bring about a hernial protrusion. The so-called ligaments of the uterus are not made to withstand any tensile stress. The structures responsible for the support of the uterus are therefore (1) the levator ani muscle and (2) the pelvic fascia. It must be remembered that

prolapse can occur in nulliparae and virgins, in which case an elongated cervix is almost invariably the cause. As in hernia, so there are degrees of prolapse; there may only be a slight bulging of the anterior vagina wall with slight descent of the cervix, or the os may descend to the vaginal orifice; or, as a final stage, the uterus may be protruded completely from the vagina. A small degree of prolapse as a rule gives more pain than a procidentia.

The treatment should be the same as that adopted in an ordinary case of hernia elsewhere, which, in short, means a truss for relief, and an operation for cure. But before discussing treatment in detail, let me say a few words about prophylaxis. Most cases of prolapse are the result of parturition, therefore it must follow that something can be done to lessen the incidence of this complication. During labour it is all-important to preserve the pelvic floor; and if it has been lacerated an efficient repair is very necessary for the future of the patient. It is so common to find a thin skinny structure where, before labour, a strong support in the form of the perineal body existed. Then, in the third stage of labour I deprecate the commonly adopted plan of forcing the uterus down in order to express the placenta; this practice must weaken the fascial supports round the uterus, and twice I have seen a careless midwife produce an inversion of the uterus by her vigorous efforts to expel the placenta for the treatment of haemorrhage; inversion is more readily produced by this procedure than by pulling on the cord. I may be guilty of heresy, but I see no harm in delivering the placenta from the vagina by pulling it out, instead of using the uterus as a wedge to push it out. In the puerperium much might be done by maintaining muscular tone, and for this end I advise not only abdominal exercises, but exercises for the levator ani muscle. The latter are carried out by telling the patient "to contract herself as if she were trying to hold in a motion." In the treatment of early cases following childbirth the patient should be made to spend most of her time in the recumbent position, but exercises should be carried out thrice daily. If the uterus has not involuted completely, a course of ergot and strychnine will be beneficial. Treatment on these lines is advised for a month, and if the prolapse is still present at the end of this time the condition must be regarded as one of hernia, and a truss in the form of a pessary is necessary. There is no question as to the relief so obtained. If a pessary or a truss gives relief and is comfortable I see no harm in its use. I use only soft rubber pessaries, and I have many patients who complain of pelvic pain immediately they cease to wear them. They must, of course, be changed and cleaned regularly. Many patients, however, are not relieved by wearing a ring pessary—either it cannot be retained, or it fails to give relief; in these cases operative treatment is essential.

I perform one operation for prolapse only, and this I call the operation for the radical cure of perineal hernia. In the last eight years I have practised Fothergill's operation, with certain modifications, without experiencing a failure. Among others, I have operated on cases of procidentia which had previously undergone some form of ventrofixation operation with subsequent recurrence of symptoms, and obtained a complete cure. The chief points in the operation are: (1) careful pre-operative preparation, (2) amputation of the cervix, (3) restoring the muscular and fascial supports under the bladder, (4) restoring the muscular and fascial layers in front of the rectum, and (5) building up a new perineal body.

CONCLUSION.

Earlier in this address I threw doubt on the value of many operative measures for the relief of chronic pelvic pain. I close it with an enthusiastic faith in the surgical treatment of the most constant cause of this condition. Why is this? It is because surgery is able to restore a damaged part to its originally correct anatomical state. In the many "pexy" operations which are practised, the failure of them is, in my opinion, attributable to the fact that organs are placed or tied up contrary to Nature's intention.

NON-INFECTIVE ARTHRITIS IN WOMEN.

BY

E. P. CUMBERBATCH, M.A., B.M.Oxon., M.R.C.P.,
MEDICAL OFFICER IN CHARGE OF THE ELECTRICAL DEPARTMENT OF
ST. BARTHOLOMEW'S HOSPITAL;

AND

C. A. ROBINSON, M.B., B.Ch.CANTAB., D.M.R.E.,
PHYSICIAN IN CHARGE OF THE ELECTRICAL DEPARTMENT OF THE WEST
MIDDLESEX HOSPITAL; CLINICAL ASSISTANT IN THE ELECTRICAL
DEPARTMENT OF ST. BARTHOLOMEW'S HOSPITAL.

WHEN the process by which a morbid condition arises is obscure its elucidation may be facilitated by considering the results of treatment. This may be true whether the method of treatment has been arrived at empirically or not. We have found that the process producing arthritis may, in a certain class of case, be brought to an end by heating the pelvic organs by diathermy.

Since 1912 the treatment of arthritis by diathermy has been investigated in the electrical department of St. Bartholomew's Hospital. Before 1914 it was found that diathermy had a marked effect on gonococcal arthritis when applied to the affected joints. After the war it was found that it was unnecessary to apply the current to the joints if the application were made to the foci from which dissemination occurred—namely, the cervix uteri in women and the prostate and vesicles in men.

As the work proceeded it became evident that patients were being successfully treated in whom gonococcal infection was more and more doubtful, and later that cases of arthritis, both in men and in women, in whom gonorrhoea had definitely not occurred were also efficiently treated by diathermy. It was supposed that the effect upon the arthritis was due to the action of the current upon the cervix or prostate and vesicles infected with organisms other than gonococci.

A series of cases has, however, occurred in which it seemed clear that no infection existed. These cases were either in young women in whom the onset of the arthritis coincided with the establishment of menstruation, or in women at or about the age of the cessation of the menstrual function. An illustrative case at either end of menstrual life will be described later. It is held, we believe, by most authorities that the so-called rheumatoid arthritis is in all cases due to a focus of infection giving rise to a toxic arthritis, or to an arthritis in which there is actual bacterial invasion of the structures of the joint. This opinion is held in spite of the fact that in many, if not in most, cases a focus of infection is not found. We have no doubt, however, that the number in which a focus is not discovered would be considerably reduced if the cervix were more often examined.

The so-called rheumatoid arthritis is far commoner in young women than in men. It seems a fair deduction from the results of this treatment that this is due to the fact that the cervix is liable to an infection capable of producing the arthritis, and that although the prostate may play a similar part in the causation of arthritis in men it is not nearly so commonly infected with organisms other than gonococci in comparatively young persons.

There still remain cases in which a focus cannot be discovered and which are not due to an infective toxæmia. It is true that in these the teeth are often affected by the same process as the joints, and are held to be responsible for the toxæmia when they are really a manifestation of it. This accounts for the great number of cases in which complete removal of the teeth is not followed by any improvement in the condition of the joints.

It seems that at all events some of these cases of arthritis—namely, those in which no focus of infection can be found—are due to absence or deficiency of hormones of the ovary or other pelvic organ. These are amenable to treatment by diathermy applied to the pelvic organs. Heating of these organs by diathermy has resulted in subsidence of the inflammation of the joints and complete functional restoration, unless such new bone formation or other organic changes have taken place as to render restoration of function impossible.

In virgins the treatment may be effectually carried out by means of a rectal electrode, the procedure being similar to that used for heating the prostate in men. In married women an intrapelvic electrode, introduced into the vagina, is used.

CASE I.

In a girl, aged 16, the illness began at the end of 1923. The symptoms were then a general feeling of illness and pain in the left hip. She was confined to bed for a short time, but was able to walk after this till just after Easter, 1924. At this time the knees became swollen and stiff, and when admitted to the West Middlesex Hospital on May 1st she was unable to walk. Most of the joints were affected, the knees and wrists most severely.

When first seen the knees were flexed and could not be extended beyond a right angle, and the wrists were fixed in an extended position; the patient was thin and anaemic. Diathermy was applied by a rectal electrode on eight occasions, over a period from June 2nd to June 30th, 1924. At the end of this time the knees could be completely extended and there was full range of movement of the wrists and fingers. There were no pains and she was beginning to walk. Synovial swelling of the knees was still present. The quadriceps extensor muscles, especially the vastus internus, in both limbs were wasted.

Massage and exercises were then commenced. On August 8th her general condition was good and she walked fairly well, but with an awkward gait. On November 3rd she walked well. All joints were freely movable. There was slight swelling of the wrists and knees. On November 27th the wrists and knees were still slightly swollen. She was then doing physical exercises, including skipping.

At Christmas, 1925, complete functional restoration of all joints had taken place. She was fat and well, but still had an awkward gait. Menstruation had started at the age of 15, and had been regular for six months. It then ceased for six months. At the end of this time it was re-established and remained regular afterwards.

CASE II.

A woman, aged 40, suffered from generalized arthritis resulting in much suffering and ill health. She was so crippled as to be hardly able to walk with the aid of two sticks. She was thin and had a sallow, unhealthy appearance. There was a marked tendency to growth of hair on the face. The wrists, knees, and ankles were swollen, painful, and tender. The right knee could be fully extended, but the left was flexed and could not be extended and the patella was fixed. The left hip was flexed and fixed in that position.

The illness had begun two and a half years previously, and she had had a long course of treatment, including various forms of electrical treatment. During this the tonsils had been removed without effect. Treatment by diathermy applied by a rectal electrode was begun on January 24th, 1921. At the end of one month her general health had much improved, and she had gained 7 lb. in weight. The joints were more movable and almost free from pain. Treatment was then left off till November, when she was found to have continued to improve during the interval. Her general health was good and pain slight. The right knee was normal, the left knee only slightly movable from the fixed position of 120 degrees. The left hip was still fixed. The treatment was renewed for one month and then left off till March, 1925. At this time her general health was good. There was no pain, but the left knee remained fixed to 120 degrees and almost fixed.

During the last course of treatment she had menstruated quite normally, though the periods had been absent for four or five years previously. X-ray examination of the left knee showed diminution of joint space, great lipping of upper and lower margins of the patella with osteophytic formation, and extensive lipping of tibia and fibula at joint surfaces, with a fair amount of bone destruction.

It is obvious that when the destruction and new bone formation in the joint has advanced to such a condition as existed in this case in the left knee, restoration of function is out of the question. The treatment resulted, however, in relief of pain and in restoration of function in the other joints, and a return to good general health. It is only when the arthritis is recent and destruction and organic changes of bone have not proceeded beyond a certain point, that complete functional restoration may be obtained, as occurred in the first of these two cases.

Both of these patients were virgins, and in neither was there any evidence of infection of the pelvic organs. In both there was evidence, apart from the arthritis, of deficiency of ovarian internal secretion. In the younger of the two patients it may be considered doubtful whether the onset of puberty can be considered abnormal. There is, however, some evidence of deficiency of ovarian internal secretion in the interval of amenorrhoea after the original onset of menstruation. In the older there was evidence of deficiency of ovarian internal secretion in the early cessation of menstruation and in the growth of hair on the face. It is noteworthy that in this case, as in some others of a similar kind treated in this way, the menses appeared after having ceased for some years.

Corroboration of the possibility of stimulating the formation of the ovarian hormone by heating the pelvic organs

consists in the relief by this means of subjective symptoms and irregular haemorrhage due to the deficiency of ovarian internal secretion at the menopause. Several such results have been obtained recently in this way in the electrical department of St. Bartholomew's Hospital.

The object of this paper is to put forward the contention that there exist cases of arthritis occurring at either end of menstrual life which are not due to infection, that in some of these, at all events, the arthritis is due to deficiency of ovarian hormone, and that in these the arthritis and accompanying ill health are efficiently treated by heating the pelvic organs by means of diathermy.

This is the first of a series of articles which we hope to publish on work carried out in the electrical departments of St. Bartholomew's and West Middlesex Hospitals on the treatment of arthritis and of gynaecological cases.

A REVIEW OF THE LATER RESULTS OF INSULIN TREATMENT.*

BY

A. P. THOMSON, M.C., M.D., M.R.C.P.,

ASSISTANT PHYSICIAN TO THE GENERAL HOSPITAL, PHYSICIAN TO THE CHILDREN'S HOSPITAL, BIRMINGHAM.

In this paper I propose to review the results obtained by the insulin treatment of 100 cases of diabetes, in all of which the treatment began over a year ago, and in rather more than half of which it has continued for nearly two years. Detailed consideration of early progress under insulin treatment will be omitted—first, because this matter has already been extensively reported, and it is now well known that the vast majority of cases do very well in the initial period; and secondly, because the progress of patients after their return to ordinary life is a matter of greater practical importance.

The cases have been taken in strict chronological order, and no case of any type that has received insulin treatment for diabetes has been excluded, with the exception of 15 patients it has been impossible to trace. Of the 100 cases (44 in hospital, 56 in private) whose records are available, 25 are now dead (13 in hospital practice, and 12 in private); 15 deaths occurred during the early period of treatment, the remainder within a few months of beginning insulin.

Causes of Death.

In no fewer than 17 of the 25 cases it was clear that death resulted from some complication of the diabetes: 5 of them had severe tuberculosis (4 pulmonary and 1 renal); gangrene was present in 4; 2 patients died of angina, and 2 of heart failure without coma (both were over 70 when insulin treatment was tried as a last resort); 3 cases had gross septic infections (1 mastoid disease, 1 pyonephrosis, and 1 ischio-rectal abscess); 1 case of renal infantilism with slight diabetes died of uraemia; 7 cases died of coma that was apparently uncomplicated (there were *post-mortem* examinations in 3 only). In 2 early cases which occurred when the supply of insulin was limited the treatment was inadequate; 2 others were of the special type of coma to be described later; in 1 case death followed rapidly from coma when insulin was left off against advice and an unrestricted diet was taken; the treatment of the 2 remaining cases was begun when the coma was far advanced. One patient died as the result of insulin treatment, a woman with diabetes of moderate severity who was doing well when she suddenly became unconscious. The diagnosis of hypoglycaemia was made at once, and glucose was given intravenously. She appeared to rally slightly and a small injection of adrenaline was made intravenously to expedite recovery, but ventricular fibrillation occurred and was immediately fatal. Death was probably due to the adrenaline, and this case demonstrates again the danger of the intravenous injection of this drug.

An examination of these details shows that the 25 per cent. mortality recorded in this series gives too serious an

* Being the substance of a post-graduate lecture at the General Hospital, Birmingham.

impression of the true position of patients treated by insulin; it is clear that many (at least 10) of these patients who died were fatally ill from causes other than diabetes before treatment was begun, and I think it is fair to point out that with greater experience of insulin four others might have been saved.

Coma and its Treatment.

The general features of full diabetic coma, which are familiar, need not be described, but I wish to emphasize the fact that it is comparatively rare for this serious complication to develop suddenly, and that now that insulin is available it should be possible to avoid it in a larger number of cases. Quite frequently the warning symptoms of commencing coma extend over a few days, and they are frequently ushered in by vomiting and either constipation or diarrhoea, with vague abdominal pain without rigidity. If the urine be examined diacetic acid is always present, and these symptoms, particularly if associated with hurried respiration, in a patient known to be passing sugar should call for energetic treatment.

Diabetic coma cannot, of course, be properly treated on any routine plan, but, for the sake of clearness, I will state dogmatically the important points.

The patient should be put to bed and an enema and saline purge should be given at once. Complete and repeated physical examination should be made for any complicating factor, such as sepsis, which may have precipitated the attack, and treatment of this complication will accompany the treatment of coma, and is, indeed, a feature of it; this is a matter of extreme importance, for it is probable that the majority of attacks of coma are precipitated by infection. It should be emphasized, too, that the absence of fever in severe diabetes does not warrant the assumption that no infection is present, for it is undoubtedly true that diabetics may have severe general infections (such as pneumonia) while the temperature remains normal. Hot broth, weak tea or coffee, with very little milk, should be given every hour by the mouth. If the patient cannot drink, subcutaneous, rectal, or intravenous salines should be given instead; 10 grains of sodium bicarbonate should be given with each drink until the urine becomes alkaline, and then should be discontinued, for excess of alkali may do harm.

In average adult cases I give 30 units of insulin at once, 20 units in two hours' time, and 10 units two hours later, making 60 units in the first four hours in decreasing doses. Later, 10 units are given every four hours for as long as the glycosuria persists. The nurse is told to obtain hourly specimens of urine, by catheter if necessary, and to test them at once for sugar; immediately a specimen of urine is obtained free from sugar, 4 oz. of hot milk and some thin bread-and-butter is given by the mouth.

With treatment of this kind, most cases of diabetic coma, not too far advanced and uncomplicated by gross sepsis, recover very well.

A Special Form of Coma.

I wish to draw attention to what is, I believe, a special form of coma occurring in patients previously treated by insulin; the following is a description of a case illustrative of the condition to which I refer.

A farmer, in whom diabetic symptoms first declared themselves in July, 1921, when he was 30 years of age, was treated in September of the same year on Allen lines in a nursing home, and returned to his ordinary work on a diet of 1,500 calories, with a carbohydrate content of 30 grams, protein 70 grams, and fat 110 grams. He was then sugar-free and his blood sugar was normal.

During the next two years he had several breakdowns; it was necessary to restrict his diet still more, and he became extremely wasted. Early in 1923 he slipped into coma, and was rescued by some injections of pancreatic extract which I was then using for some experimental work with animals in conjunction with Dr. A. F. Wright. In May, 1923, insulin became available and he steadily improved. In September of the same year the daily dose of insulin was 40 units and he began to gain weight.

I saw nothing of him until November, 1924, by which time he had become extremely fat. I warned him against excess of diet and told him to take free exercise, but within a month he was again admitted to a nursing home in coma. He was treated energetically with insulin (120 units in twenty-four hours) and that his blood sugar was normal, that his urine was free from sugar and contained no diacetic acid, he remained unconscious and

extremely ill. His pulse became very rapid and feeble, respiration was shallow and slow, and, although glucose was given intravenously with further doses of insulin, he died.

Shortly afterwards I saw a woman who had run a very similar course; and after her second attack of coma, when she remained unconscious with normal blood sugar and without glycosuria, I performed lumbar puncture, withdrew about 20 c.cm. of cerebro-spinal fluid, and injected 5 units of insulin, diluted with 10 c.cm. saline, direct into the theca. Within a few hours she was conscious and well on the way to recovery. The cerebro-spinal fluid gave a strongly positive Rothera test, and contained 0.5 per cent. sugar. In a third similar case I injected the insulin by cistern puncture. Recovery followed in about the same time, but the method appeared to have no striking advantage over simple lumbar puncture and injection.

I do not suggest that these cases are very common, but, on looking back over the hospital records, I have met with two other fatal cases. Both had been previously treated with insulin, and were admitted to the hospital in coma. The notes show that some hours before their deaths the blood sugar was normal and the urine free from sugar and diacetic acid.

The explanation of these cases is, I believe, that the changes in the blood after administration of insulin occur very much more rapidly than they do in the cerebro-spinal fluid, and that the medulla is poisoned by the acidosis of the fluid while the blood is normal. Gross disparity between the condition of the blood and cerebro-spinal fluid is more likely to occur in cases already undergoing treatment by insulin. I mention these cases because it seems to me that they justify one further measure in the treatment of diabetic coma when the response to the normal treatment by insulin is not satisfactory within a short time—namely, intrathecal injection of 5 units of insulin diluted with saline.

Twenty-one attacks of coma were treated—9 in hospital and 12 in private practice. Of the 9 hospital cases 5 recovered, but all of these died within a year; they were all cases in which the diabetes was complicated by other factors. Of the 12 attacks treated in private practice 5 cases died, but the remaining 5 are in good health and two of these have had two attacks of coma each.

The Survivors.

Of the 75 patients who survive 14 are in poor or moderate health—that is, they are still unable to do their usual work. I have made a careful analysis of these cases to discover the causes of failure in them, and I have come to the conclusion that the principal factors, in order of importance, are:

1. *Incidence of Infections.*—Frequent catarrhal illnesses, the source of which is commonly in the nose and throat; they seem to be due to diminished resistance. Of this group several have refused treatment for fear of operations. In three cases in which vaccines have been used no benefit has resulted.

2. *Lack of control of diet* due to want of care or intelligence on the part of the patient.

3. *The Secrecy of the Disease.*—There appears to be a small group of cases in which, despite efficient treatment, the condition becomes more serious as time goes on.

Of the 100 cases, 61 remain in good health, able to do their ordinary work comfortably, some doing very hard work. They include manual labourers, men controlling large businesses, and children going to ordinary schools and developing normally. In several women menstruation has been normal and two of them became pregnant; one of them unfortunately had an extrauterine gestation which ruptured. My colleague Mr. B. T. Rose operated, and she recovered and is still well. In the other case the pregnancy was terminated.

This seems to be a satisfactory result, particularly when it is remembered that in this early period the cases treated were severe, as many of those of moderate severity did not receive insulin owing to expense and the uncertainty of its value.

An examination of the records of these 61 cases shows that the chief factors of success in treatment are the adequate instruction, self-control, and intelligence of the

patient, coupled with circumstances which are favourable to good personal hygiene. The care of the teeth, of the nose, nasal sinuses, and throat, the regulation of the bowels, scrupulous attention to the feet, are details which in the diabetic assume great importance. Careful routine overhauling to discover and eradicate focal sepsis should be an essential in the after-care of every diabetic patient, whether treated with insulin or not.

As regards the diet, I have used slight modifications of the scale which I have already described (BRITISH MEDICAL JOURNAL, March 15th, 1924, p. 457), and my aim has been to keep the patients at work at a weight a few pounds less than the average for their age and build; the dose of insulin has been adjusted accordingly, but I do not exceed 40 units daily for general use, and the diet and weight are reduced when necessary.

Whether it is essential to keep the blood sugar normal and the urine constantly free of sugar is a question of interest and practical importance; on theoretical grounds it is desirable to do so, and all those in whom this aim has been attained have done well; but I am bound to confess that they are few, and I have been surprised to find that in spite of the fact that the greater number do at times pass sugar they nevertheless remain in good health. I insist that no effort should be spared to keep the first specimen passed in the day free from sugar, as by that means it is possible to make sure that the blood sugar is normal or nearly so during the hours of sleep, and as an ideal this has been of practical value. Conscientious patients become very worried about occasional glycosuria, which, in the many vicissitudes of their daily lives, seems to be almost unavoidable, and it is a relief to be able to tell them that they need not worry provided the early morning specimen is free. Elaborate blood sugar control is unnecessary once the condition has been stabilized.

Certain other points emerge which are of importance. As a general rule those patients have done best in whom insulin treatment has been instituted soon after the symptoms of diabetes have first appeared. This is particularly true of the younger cases; it is, I think, significant that there is no record in this series of satisfactory subsequent progress in a patient under 25 years who put off insulin treatment for more than four months from the onset of symptoms, even when dietetic treatment had been stringent and efficient during the early period of the disease. The conclusion is warranted that all young diabetics should be treated with insulin without delay.

I have been compelled to revise my former opinion that insulin treatment in the elderly and long-standing cases of diabetes was not of much value, for I am bound to admit that several cases of this type have shown remarkable mental and physical improvement with it. In early days I was misled by the fact that in this class of patient improvement comes more slowly and much less dramatically than in the young, and it may be some months before the advantage is manifest.

There appears to be no definite relationship between the rate of early progress and the ultimate prognosis. Recovery of tolerance undoubtedly occurs in a greater proportion of cases and to a far greater degree than in the days of simple dietetic treatment. Four of my patients (all of them over 40) have given up insulin after varying periods of treatment, and have now a tolerance for an adequate diet with nearly 100 grams of carbohydrate. The most striking case is that of a man who, on leaving hospital over a year ago, took 60 units daily and yet did not remain sugar-free. He has now been without insulin for three months and remains sugar-free with a more liberal diet. It is unwise for the border-line case to give up insulin; several patients have attempted to do this and to continue treatment by dieting alone, but almost without exception they are glad to renew the irksome injections for their "tonic effect."

Summary.

1. Of 100 cases of diabetes of all types treated with insulin and dieting 75 survive—61 in good health and 14 in poor or moderate health. This result will almost certainly improve in future, as during this period the treatment was mainly limited to the more severe cases. Of the 25 deaths that occurred, 1 resulted from the treat-

ment and 10 others were not directly due to diabetes but may have been accelerated by it; in 17 of the fatal cases there were definite complications.

2. Of 21 attacks of coma either actually treated in the stage of full unconsciousness or close to it, 12 recovered. Of the 10 patients concerned, 5 remain in fairly good health; the others have since died.

3. A type of persistent coma which is, I believe, particularly liable to occur in treatment by insulin is described. Recovery from this type of coma after intrathecal injection of insulin is recorded.

4. The importance of early insulin treatment in young patients is emphasized.

5. All cases which have kept a normal blood sugar and have remained free from glycosuria have done well; their condition at this time, however, does not appear materially better than that of those who have shown glycosuria at times but who nevertheless have managed to keep the early morning specimen free.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

FISSURED FRACTURE OF THIGH WITH FEW SYMPTOMS UNTIL A MONTH LATER.

THE following history of fracture of thigh in a youth is so unusual as to warrant its being reported.

A lad, aged 16, a pony driver in a pit, met with an accident on October 13th, 1925, which was diagnosed as a contusion of the right hip; he had some discoloration in this region. He was able to walk about after the accident, at first with the aid of a stick; by November 14th the contusion had cleared up, and he could walk and bend his hip perfectly and felt quite well. He returned to work in the pit on November 16th; there was no work in the pit on November 17th, but he worked on November 18th. Whilst out for a walk on November 19th he slipped on frosty ground with his left foot and states that his right leg gave way. He was removed to hospital, where x-ray examination revealed an oblique fracture of the right thigh at the junction of the upper with the middle third, and marked angular deformity.

At subsequent proceedings in the county court, taken under the Workmen's Compensation Act, it was maintained successfully that a result of the accident on October 13th had been a fissured fracture of the right thigh; it was given in evidence that there was callus when the x-ray examination was made six hours after the accident on November 19th, and that the callus was not firm on account of the youth walking about too soon.

I have never before heard of a case where a person with a fractured thigh could walk about, practically without pain, resuming work for two days, and that then a trivial accident should reveal a fissured fracture of a month earlier.

Barnsley.

H. A. L. BAXHAM.

ACUTE GASTRIC ULCER ASSOCIATED WITH PERNICIOUS ANAEMIA.

The combination of acute gastric ulcer and pernicious anaemia in the following case seems to be of sufficient interest to be placed on record.

A married woman, aged 42, was admitted, as an emergency case, to the Royal Alexandra Infirmary, Paisley, on March 1st, 1926, with a history of having, on February 25th, while at housework, retched and vomited 10 ounces of dark blood; two brighter coloured vomits of similar amount followed the same day. The next day a mouthful of bright blood was brought up. Her next and last vomit was half an hour after admission—about 6 ounces of partly clotted blood. She stated that she had had "bilious turns" for two years, that she had been yellow for five weeks, but that she had been able to do her household duties quite well.

On admission the temperature was 101° F., pulse 160, and respirations 28; she was a well nourished woman. The skin was decidedly lemon-tinted and the mucous membranes very blanched. She was very collapsed. The pulse was barely perceptible at the wrist; sounds heard easily on auscultation over brachial and femoral arteries; blood pressure 115/40.

She died in thirty-six hours. Examination of the blood showed: haemoglobin 9 per cent., white cells 27,000, red cells 940,000, colour index 0.5. Poikilocytosis, anisocytosis, polychromatophilia,

and basophil degeneration were seen. There were numerous nucleated red cells and megaloblasts (33 of the latter were noted during a count of 100 white cells).

Dr. Mary B. Hannay, pathologist to the infirmary, conducted a *post-mortem* examination, and reported three simple ulcers on the lesser curvature of the stomach; a blood vessel opened into the floor of one of them. The contents of the lower small intestine and of the colon were much blood-stained. The heart was dilated, especially the right ventricle, and the muscle pale and soft, showing faint yellow mottling. The liver was fatty, and gave a faint Prussian blue reaction.

I have to thank Dr. W. Clow, to whose ward the patient was admitted, for permission to report this case, and also Dr. Hannay for permission to quote from her report.

A. M. POLLOCK, M.A., M.B., Ch.B. Glasg.,
House-Physician, Royal Alexandra Infirmary, Paisley.

CHONDRO-SARCOMA OF INDEX FINGER.

THE following case is of sufficient interest to be placed on record since the occurrence of sarcomata of the phalanges and metacarpals is exceedingly rare.

The patient, a single woman aged 21 years, was admitted to hospital on September 29th, 1925, with a large chondrosarcoma of the left index finger. She stated that, some

eighteen months before admission, the growth started as a white mark resembling a blister, and that it grew slowly. At first it was very soft, but it gradually increased in hardness. During the previous two months it had been growing rapidly. She said she had experienced no pain until a week before she was seen, and that she only came for advice because of the inconvenience caused by the size of the growth. There was no past history of rickets.

On examination a tumour the size of a billiard ball was

seen on the palmar surface of the index finger of the left hand; it was situated on the proximal phalanx. It was fluctuating in parts, had a broad base, and the skin was nowhere adherent (Fig. 1).

An x-ray photograph showed destruction of the shaft of the proximal phalanx of the index finger and a large soft tumour extending outwards; there were several areas of ossification (Fig. 2). Examination of the chest by x rays showed no evidence of secondary deposits in the lungs.

The patient was operated upon by Mr. Rodney Maingot on the day after admission. The index finger and the distal half of the second metacarpal bone were amputated. Microscopical examination of the parts removed showed the tumour to be a chondro-sarcoma undergoing myxomatous degeneration in parts. The central portion of the growth was necrotic.

Examination of the hand on February 28th, 1926, showed a painless scar. The movement and gripping power of the fingers were good, and the patient experienced but little inconvenience. There was no clinical or x-ray evidence of metastases in the lungs, or locally in the region of the scar.

I am indebted to the courtesy of Dr. Cleveland Smith for permission to report this case.

CLIFFORD H. LEE, M.R.C.S., L.R.C.P.,
House-Surgeon, Southend Victoria Hospital.

Reports of Societies.

THE CONTROL OF INFECTIOUS DISEASE.

A DISCUSSION on modern methods of control of infectious disease took place in the Section of Medicine of the Royal Society of Medicine on March 23rd, Dr. HUGH THURSFIELD presiding.

Sir JOHN ROBERTSON (M.O.H. Birmingham) exhibited charts to illustrate the incidence and mortality rates in respect to certain infectious diseases in England and Wales during the last half-century. He said that the mortality from small-pox had reached vanishing point. As to enteric fever, the difficulty was to get a case in hospital for teaching purposes. The mortality from scarlet fever, diphtheria, measles, and whooping-cough had enormously declined, though the decline in incidence had not in all cases been parallel. In dealing with infectious diseases in the past, four methods had been employed—notification, isolation, quarantine, and disinfection. Within recent years immunization methods had been added, although, of course, small-pox prevention furnished an early example of immunization, which was still the most successful. All who had been engaged in small-pox prevention would agree that the disease could be entirely abolished by general vaccination and revaccination. But in a community in which 30 to 40 per cent. of the people were unvaccinated, and an additional number not efficiently protected, it was necessary to bring into operation isolation and quarantine. A number of cases of small-pox were now so mild as to escape notification. Apparently there was very little natural immunity to small-pox—that is, few unprotected people escaped small-pox if exposed to infection. In passing he mentioned a striking case within his experience in which a book read on his deathbed by a sufferer from confluent small-pox, and not disinfected, was the means of infecting other cases in three different houses within a period of thirteen months.

In scarlet fever natural immunity played an important part. Somewhere between 12 and 20 per cent. of the population under 15 years of age were at one time or other susceptible to scarlet fever, while the rest, either by natural immunity or by reason of non-exposure to infection, escaped the disease. Natural immunity played an important part not only in preventing this disease but in reducing its virulence. Many hospital superintendents were now making use, with very good results, of the recent work done on immunization to scarlet fever, and he had no doubt that in the very near future it would be possible for the medical man to protect entirely any individual from scarlet fever. Isolation was a great convenience to the public, and was of great value to the patient acutely ill, but it had considerable disadvantages, among them the liability, unless the discipline in the fever hospital was exceptional, for the children to contract other infections. Home isolation for all but the poorest or the most severe cases was sufficient for scarlet fever. Scarlet fever was now a mild disease, and reliance must for the present be placed upon the old methods of isolation and disinfection in the hope that in the near future the work done on immunization would yield a satisfactory method of limiting scarlet fever incidence.

Diphtheria was a disease in which hospital isolation, quarantine, and disinfection had apparently accomplished nothing so far as incidence was concerned, although mortality had fallen greatly. Most cases of diphtheria should be removed to hospital for skilled supervision and nursing, though not necessarily to prevent spread. The virulent carrier cases might be divided into two groups: those who were in the carrier condition for a short time only, and the chronic carriers, who were mostly those with tonsils and adenoids needing the attention of the otologist. The Schick test had demonstrated that there existed in many people a natural immunity to diphtheria. He produced some figures relating to the recent experience in New York of immunization to scarlet fever.

In 1915 the number of new cases reported was 15,279, and of deaths 1,278; in 1905 the numbers were respectively 13,686 and 1,544, and those years were at about the usual

FIG. 1.

FIG. 2.

	New Cases Reported.	Deaths.	Persons Immunized by Toxin-antitoxin.
1921	15,110	891	42,000
1922	10,427	873	48,496
1923	8,050	553	42,818
1924	9,637	714	58,936
1925	9,051	673	38,191

level for the ten-year period. He also drew attention to the work going forward at present in Paris in the immunization of children to measles. Two public dispensaries were now open for dealing with cases of commencing measles or contacts, and good results were claimed. In conclusion he raised the question as to whether there was some non-specific general immunization of the people taking place. It seemed possible that the improved general health might confer some immunity.

Dr. C. R. Box said that there was no stereotyped method of preventing infectious disease. Each disease was to a certain extent a law unto itself, and it was only by increasing knowledge of the nature and the cause of the disease, the manner of its spread, and also perhaps the mechanism of bodily defence, that any campaign could attain success. The diminished incidence of small-pox was due, no doubt, to vaccination; that of plague, typhus, cholera, and enteric fever to sewage control, pure water supply, and general sanitary measures. He questioned whether there was such a thing as natural immunity to infectious disease. Was it not more correct to say that the body had a defensive mechanism which was brought into action on attack? He attached a good deal more importance as a result of his experience to the scarlatina carrier than Sir John Robertson appeared to do. In diphtheria he noticed that the case incidence had not materially fallen, but the mortality was greatly lowered, a tribute, of course, to treatment and nursing. The separation of virulent and avirulent carriers had also been a great help.

Dr. E. W. GOODALL agreed with Sir John Robertson's generalization that the better the knowledge of the natural history of infectious diseases the more efficient would be the control. It was now realized, however, by most epidemiologists that it was not possible to get rid of the micro-organism spreading the infection. The word "control" was loosely used; it was not the disease which was controlled, but chiefly the actions of people and animals. The methods of control available were: (1) to prevent the attack without destroying the organism, as, for instance, to preserve drink and food from contamination; (2) to kill the germs immediately, as by boiling or cooking drink and food which might have been infected; (3) to kill the insect or animal host, as the louse in typhus and the rat in plague; (4) to render the individual immune to attack. Of these methods the last was the most efficacious, but a note of warning should be raised against promising too much from immunization. The mistake of Jenner and his disciples in supposing that complete protection ensued from one vaccination must not be repeated. In the first three of the methods just cited it was not the individual who was dealt with, but the herd; in the fourth it was the individual, and that was where the trouble began, at least in this country. Immunization to measles and whooping-cough might come to be established on a firm foundation, but the best method of applying such immunization would be a nice problem for the administrator. Possibly some future bacteriologist would arise with a mithridate whereby immunization to all these infections might be secured with the one injection.

Dr. R. A. O'BRIEN described the methods and results of control against diphtheria by immunization as practised in certain residential institutions. In three such institutions in which a good deal of diphtheria had previously occurred the immunization method was introduced, and since that time, for the last four years, there had been no case of clinical diphtheria among the children tested and at once found negative or immunized and found negative afterwards. He also dealt with the immunization of nurses in fever hospitals. He estimated that for every

100 cases of diphtheria in institutions one nurse or attendant became infected, and as the total number of cases of diphtheria in this country was 50,000 a year, probably 500 cases of diphtheria occurred annually among nurses. In one fever hospital in which the number of nurses who got diphtheria amounted to about twenty each year for several years in succession, a striking fall followed the introduction of immunization of all new entrants into the service; in 1923 the number of nurses infected was four, in 1924 it was eight, and in 1925 it was four again.

Major PARKINSON mentioned experiences with typhoid fever in the early stages of the war; the sheet-anchor then was antityphoid inoculation. Tetanus was another disease which caused anxiety, but when a serum was found the disease greatly diminished in importance. At one stage the serum ran out, and immediately the figures went up considerably, but when a fresh supply of the serum arrived control was re-established. In war time, of course, the men were under complete discipline, and measures could be much more effectively applied. Moreover, there were sanitary sections which looked after the water supply, the sewage disposal, and so on, and a map showed the danger spots. It was also a help, during a campaign, to know something of the general health of the populace among whom the soldiers were billeted.

The PRESIDENT, in closing the discussion, remarked that the fall in the incidence and death rate in infectious diseases generally was not shared by influenza. Infectious disease incidence was largely a question of mass infection. When a community was carefully guarded and no massive infection was allowed to enter there would be a drop in incidence, but when the circumstances were the converse an increased incidence was noted. Sir John Robertson had pointed out that although in pneumonia there had been little reduction the death rate from bronchitis in all forms had come down. For the general drop in the bronchitis rate the better social conditions, and particularly the factory regulations imposed by the Home Office, should receive the credit.

EFFECTS OF ULTRA-VIOLET RADIATION.

A discussion on the effects of ultra-violet radiation took place at the Royal Society of Medicine, in the Section of Comparative Medicine, on March 24th. Professor FREDERICK HODDAX presided.

Two preliminary papers were read, in one of which Dr. J. F. HALLS DALLY gave an account of the principles underlying ultra-violet radiation treatment and the various kinds of lamps in use. He agreed with Professor Sonne of Copenhagen, in holding that the biological effects produced with this form of treatment were not solely a function of the ultra-violet energy, but depended also upon the luminous rays, which had a heating effect of importance in the destruction of toxins and the formation of antibodies. He spoke of the need for more research in connexion with the analgesic properties of ultra-violet radiations; his own work led him to think that these were of importance. Indeed, the medical profession was still awaiting the results of co-operative observations by chemists, physicists, and physiologists. With standard electrodes, strengths of current, positions and distances of subject, and times of exposure, the effect of groups of measured wavelengths of definite intensities should be carefully studied. The other paper was by Mr. MIDDLETON PERRY, who gave some account of successful treatment with a quartz mercury vapour lamp in veterinary medicine—skin diseases, indolent wounds and ulcers, and rickets in dogs.

Professor LEONARD HILL, in opening the general discussion, gave it as his opinion that what any source of artificial ultra-violet rays could do was neither more nor less than what the high sun could do at the seaside or in the clear country air or in the Alps. What the sun would do these artificial sources would do in seasons when the ultra-violet rays, and to a great extent the visible rays also, were cut off by the mist and cloud of our climate, not to speak of our industrial and domestic smoke-screen. A great deal of nonsense was being talked nowadays about different sources and methods of getting ultra-violet

radiation. It did not signify much what the source was, whether mercury vapour or arc, or whether a plain carbon arc or one with a core of iron, magnesium, or tungsten. Results could be obtained from any of these different sources. One distinguished clinician had stated that nothing should be used except the short-flame carbon arc with direct current, giving a flame that never flickered. That dogmatic kind of statement was unwarranted. One could get equally good results with long-flame arcs, which incidentally were far more economical in cost. The intensity of ultra-violet radiation obtained depended upon the energy which was put through the arc. If the energy, say, of a 200-volt current were broken up into four poles instead of two the same ultra-violet energy would not be forthcoming as from two in series. By careful management comparatively weak sources of ultra-violet radiation might furnish whatever was necessary, but, of course, such weak sources were time-wasting. It had to be borne in mind also that the skin rapidly immunized itself against the dose it was receiving. The horny layer thickened, the skin became oedematous, and penetration correspondingly difficult. The active region in the ultra-violet spectrum was from 3,200 to 2,400 Angstrom units. Rays shorter than this lower limit would kill bacteria, infusoria, and so on, but would not penetrate the horny layer of the epithelium. He had had his skin subjected for half an hour to ultra-violet radiation of a wave-length of 2,320—an intensity which would kill all infusoria in a drop of water in a minute or so—and no erythema was produced at all. A slight erythema was produced with a wave-length of 2,500, and the maximum erythema effect was in the region 2,950-3,000. He passed on to speak of the conclusions of the long investigation on rickets. By ultra-violet radiation stearyl could be activated so that in a minimal dose it would cure rickets. If 1 mg. a day of the activated stearyl were given to the animal there would be no rickets. The activation was brought about by half an hour's exposure. This activated stearyl or cholesterol was vitamin D. Ultra-violet radiation, therefore, could produce a vitamin, and produced it, as physicists told them, by altering the energy of the atoms. When eaten by the animal this activated substance enabled it to absorb from its alimentary canal the minimal quantity of salts of phosphorus and salts of lime which was deficient in the diet, so that what was previously wasted in the faeces and not absorbed was now absorbed and went to build the bones. With regard to respiratory metabolism, he emphasized the importance of skylight. The sky was the most valuable source of ultra-violet rays. Bright clouds and blue sky gave even more ultra-violet radiation than the high sun, and far more than the low sun. Respiratory metabolism might also be put up by 100 per cent. in winter, not to any measurable extent by ultra-violet rays, but by exposure to wind and cold air. That was one of the great secrets of open-air treatment; exposure to cold put up the appetite, toned the muscles, and so on, and to this might be added the energetic action of ultra-violet rays and of visible rays also on the skin. In conclusion, Professor Leonard Hill referred to the need for studying the stimulating and lethal effects of ultra-violet radiation in different doses on the living cell.

Dr. M. WEINBRENN said that, while it was always possible to measure what was being emitted by the ultra-violet source, it was not possible to measure what the patient was absorbing. It was not like x-ray work, where the pastille dose could be repeated with fair certainty. The erythema dose in ultra-violet was quite vague and alterable. It was this uncertainty which gave a vogue to empirical methods, and brought about the many different types of apparatus. He went on to speak of the proved value of ultra-violet radiations in surgical tuberculosis, especially from the long-flame arc, and illustrated a number of cases with the object of showing that the existence of a pulmonary condition need not contraindicate ultra-violet treatment in surgical tuberculosis.

Dr. A. EIDSNOW spoke of experiments in which he had taken a share at the National Institute for Medical Research. In these experiments no results at all of any great biological significance had been found when radiations of a wave-length longer than 3,000 Angstrom units

had been used. It was possible that these longer radiations would have some effect if employed for a longer time, but so far as he was aware it was not possible to get any of the beneficial results which were put down to light treatment without some of the so-called shorter ultra-violet rays. Without these rays it did not seem possible to cure rickets, for example, or readily to destroy bacteria, or to produce without difficulty an erythema of the skin. The reason why these shorter waves were so important was their greater absorptibility by the irradiated tissues. He laid stress upon the importance in experiments upon animals or in the treatment of patients, when the object was to increase the bactericidal power of the blood, of getting the erythema dose. Short of that dose there seemed to be no effect at all. It had been found that if a very small area of skin, corresponding to 1 to 5 sq. cm. per kilogram body weight of the animal, were exposed even for a full hour a rise in the bactericidal power of the blood could not be obtained, the reason being that the area of skin was too small. On increasing the area exposed to 15 to 40 sq. cm. per kilogram there was a definite rise in bactericidal power after five minutes' exposure; but on exposing a still larger area—100 to 120 sq. cm.—no rise in the bactericidal power of the blood was manifest at all, either with a small or a large dose, the blood even appearing to be a little weaker. This was due to the surface area of the skin exposed being too large. By a system of careful exposure of a moderate area of skin, always aiming at producing a minimal erythema, and not repeating the dose on the same area at too short intervals because of the great tolerance of the skin for light—the skin desquamating under light action and thereby cutting out the whole ultra-violet effect—one might hope to get the maximum effect in increased bactericidal power of the blood.

THE ACUTE ABDOMEN IN CHILDHOOD.

At a meeting of the London Association of the Medical Women's Federation on March 9th, Dr. CHRISTINE MURRELL, the President, in the chair, Miss GERTRUDE HERZFELD gave an address on the acute abdomen in childhood.

Miss Herzfeld first related the differences between the pathology of this condition in adults and in children. In children the lesions were limited to the embryological mid-gut, corresponding to the small intestine and the first two-thirds of the large intestine. The manifestations of inflammatory or obstructive conditions were more speedily noticeable in children. Inflammation proceeded to suppuration much more rapidly, and obstruction soon gave rise to symptoms of toxæmia. For these reasons the practitioner should not wait to make a differential diagnosis once he was convinced of the presence of an acute condition in the abdomen, but should at once call in surgical aid. Prior to laparotomy the child should be kept warm and given plenty of fluid; subcutaneous saline injections should be administered if there had been much vomiting. It was the speaker's custom to give atropine in large doses—gr. 1/200 to gr. 1/150—to infants under 2 before operation, and gr. 1/100 to children over 2. Warmth in the theatre, speed in operating, and gentle handling were essential to success. Only two incisions were used by her: the gridiron incision when appendicitis or an intussusception proximal to the transverse colon was suspected, otherwise a vertical paramedian incision. Post-operative saline infusions were always given. The conditions giving rise to an acute abdomen in childhood could be divided into inflammations and obstructions. Among the former appendicitis (50 per cent. of all abdominal cases), pneumococcal peritonitis, streptococcal peritonitis, Meckel's diverticulitis, and tuberculous abdomen had to be considered. Congenital obstructions to be looked for included imperforate anus, congenital hypertrophy of pylorus, maldevelopment of gut, bands, and Meckel's diverticulum. Acquired obstructions might be due to intussusception (20 per cent. of abdominal cases in childhood), tuberculous peritonitis, hernia, or volvulus. Miss Herzfeld discussed in some detail acute appendicitis and intussusception as being relatively common conditions, and gave an account of recent investigations into the rare condition of pneumococcal peritonitis. Acute appendicitis

could occur at any age, but generally the patient was over 2 years. It was rarely diagnosed before suppuration supervened; over 90 per cent. of Miss Herzfeld's cases were already suppurating at operation. She had found pus as early as within twelve hours of the first attack. Vomiting was almost invariable except where the appendix was in the pelvis, in which case pain might be localized at the umbilicus in the young child, or in the suprapubic region in the older one. There might be frequent and painful micturition through involvement of the bladder, or diarrhoea. There was little rigidity of the abdominal wall, but on rectal examination tenderness was found not only during insertion of the finger, which was usual in normal children, but on movement of the finger-tip in certain directions. The feature of inflammation of a retro-axial appendix was a lack of resistance in the abdomen associated with posterior rigidity in the region of the lumbar muscles; vomiting might occur. If the appendix was associated with an undescended caecum the rigidity and tenderness were to be found higher up in the abdomen. The differential diagnosis of appendicitis from diaphragmatic pleurisy and pleural pneumonia could be very difficult. In the last condition the rigidity and tenderness were not so well marked nor so persistent as in appendicitis. Sometimes a re-examination twenty minutes after the first examination revealed a shifting of the signs to another place. The general appearance of a child with pneumonia was characteristic. Acute and subacute pyelitis could be distinguished from appendicitis by a microscopic examination of the urine, which was usually acid, and by the presence of lumbar tenderness. In ileo-caecal tuberculosis abdominal tenderness was very marked but rigidity was less, and the child on the whole was not so ill. This condition might be very difficult to distinguish from appendicitis, and in doubtful cases it was better to explore. The possibility of cyclic vomiting must be borne in mind and excluded, since an anaesthetic was injurious in this condition. The history of vomiting previous to the attack and the presence of acetonaemia were diagnostic features. Pneumococcal peritonitis was a rare condition, but the mortality was high (70 to 75 per cent.) irrespective of treatment; it could be primary (idiopathic) or secondary to pneumonia or some other lesion. The pathology of the primary form had only been determined by Professor J. Frazer and Dr. Macartney of recent years in Edinburgh. It occurred only in little girls of the hospital class, the average age being 5½. It began as a pelvic peritonitis, and was an ascending infection, through the vagina, in children who had a vaginal discharge. The class incidence might be accounted for by the inadequate clothing and the habit, among the poorer children, of sitting on dirty steps. A septicaemia rapidly followed the peritonitis, with a positive blood culture in six to twelve hours. Experimental work on rabbits had enabled the course of infection to be traced, and had proved that the blood infection was a secondary one. The child suddenly complained of acute abdominal pain, followed by vomiting, delirium, and high temperature. In the less acute cases the septicaemia might be delayed for forty-eight hours. The only possible treatment was drainage of the lower abdomen. Blood transfusion had not proved of much avail. The typical features of intussusception were onset of acute abdominal pain in a fat, strong, healthy baby, usually a boy of over 4 months. The usual history was that the child screamed and drew up his legs, then "fainted away," and, exhausted, fell asleep, only to awake half an hour later with another attack; vomiting would begin at this stage, and sooner or later blood would be passed per rectum. Since the contents of the bowel distal to the ileo-caecal region had first to be emptied, blood was not necessarily passed at once. Miss Herzfeld quoted cases to show the difficulty of diagnosis even when blood was passed. It was unwise to operate unless the tumours could actually be felt under anaesthesia. If the patient was under a year old reduction alone should be performed at operation, for any mutilation at the time was not well borne by the infant.

Dr. HAZEL GREGORY pointed out that in children rigors, if present, were pathognomonic of acute *B. coli* pyelitis; and Miss L. MARTINDALE described a fatal case of pneumococcal peritonitis in a child of 5.

Reviews.

THE BASIS OF VITAL ACTIVITY.

THIS little book on *The Basis of Vital Activity* is a review of five years' work at the St. Andrews Institute for Clinical Research by its distinguished director, the late Sir JAMES MACKENZIE. Much of it has already appeared in various articles published by him in this JOURNAL, and also in the last edition of his textbook on *Diseases of the Heart*, reviewed in our columns last year. The reader will quickly perceive that although it is described as a review of five years' work it is really a summing up of forty years' observation and thought by one of the most original physicians of our time.

Mackenzie did not set out at St. Andrews to study disease as a whole. He began with the intention of noting the earliest symptoms of common and chronic diseases and of watching their development during the lifetime of the individual. He found that while the number of symptoms of disease was constantly being added to, the explanation of symptoms was sadly defective. In order to make any progress he had to find out certain laws or principles underlying the production of symptoms, and the extent to which he had got is recorded in this book.

When Mackenzie began his epoch-making study of heart disease he was fortunate in having before him the recent physiological investigations and experiments of Gaskell on the functions of the heart muscle. The clinician showed how the work of the physiologist was confirmed by a study of diseased conditions of the heart. Pursuing a wider study of disease processes in general Mackenzie found that physiological teaching failed him. Many so-called physiological laws proved to be wrong when tested clinically, or the experiments were too artificial to be of any value, or knowledge was entirely absent regarding the ordinary vital processes and cellular action. Mackenzie therefore proceeded to deduce from clinical observation certain physiological laws and to elucidate physiological processes. These are here described and discussed. It will be interesting to find out whether physiologists will accept these views and will not be biased by the fact that they come from a clinical observer and thinker, and not from a laboratory.

Scottish theology demands a sense of sin on the part of the sinner before any real repentance can follow. English medicine in the person of Sir James Mackenzie demands a sense of ignorance on the part of the clinical observer before any real progress can be made. "He was always recognizing his own ignorance, and this stimulated him to further investigation and thought. He found that "a lack of guiding principles is responsible for many haphazard methods," and that "mere observation of phenomena is usurping the place of deduction and discovery." One of his basic principles is that "all vital activities are the outcome of the functioning of living cells." Among the forms of vital activity he deals with are the processes known as "contraction," "conduction," "inhibition," "control," and "secretion." In the performance of their various functions living cells are never at rest; they are either discharging energy or renewing it. Modifications of cell activity can only be brought about by hastening or delaying the renewal of energy. Cells in discharging their energy exhibit their peculiar function (for example, contraction) and at the same time discharge an impulse. This impulse exerts an influence on neighbouring cells by increasing or delaying their period of renewal of energy. The application of these and other basic principles to the clinical phenomena of disease, and more especially of chronic heart disease, is dealt with in the later part of the book.

While all readers will find this book interesting and instructive, we should like more especially to direct the attention of research workers to it. Often the research worker does not know what profitable line of investigation to take up, and often the path followed leads nowhere.

The Basis of Vital Activity. By Sir James Mackenzie, M.D., F.R.S., F.R.C.P., LL.D. With a Foreword by JAMES ORR, M.B. London: Faber and Gwyer, Ltd. 1925. (Cr. 8vo, pp. 122, 6s. net.)

Mackenzie was a brilliant and successful research worker. By no means the least valuable part of this book are the indications it gives as to many fruitful lines of research. The book may be said to be packed with them.

TREATMENT OF GONOCOCCAL INFECTION BY DIATHERMY.

THE lack of progress in the treatment of gonococcal infections may be illustrated by the story of the officer commanding a venereal hospital in France who, when asked if there had been any reduction in the average of six weeks for the treatment of gonorrhoea, replied that he thought the average in his hospital had been reduced to forty-one days! In their book on the *Treatment of Gonococcal Infection by Diathermy* Drs. CUMBERBATCH and ROBINSON point out how unsatisfactory is the treatment of infected joints, of the cervix uteri and urethra in the female, and of the prostate in the male, whether by irrigation, external applications, or vaccines. On the other hand, the gonococcus can be destroyed by a temperature which is not high enough to damage the living tissues. Hence the experiments carried out by the authors for some years past in the use of diathermy, in the electrical departments of St. Bartholomew's and the West Middlesex Hospitals. By their methods the tissues of the body conduct electricity and are heated by the current; so that the poor conductivity of the tissues for heat plays no part, because they are conducting, not heat, but electricity. As the diathermy current is restricted to a relatively small region, a high degree of heat can be produced without harm to the rest of the body. The gonococci are destroyed by the heat. In almost all their cases of gonococcal arthritis Drs. Cumberbatch and Robinson were able, within a comparatively short time, to abolish pain, reduce the swelling, and increase the range of movement. They were convinced of the therapeutic power of diathermy when they found that application to the original site of infection led to the disappearance of pain and swelling in infected joints. They attribute the failure of the treatment so far in urethritis in the male to the difficulties in the elaboration of a suitable technique. It will be noted that the authors of this book have contributed to our columns this week a paper in which they have got some remarkably good results in the treatment by diathermy of non-infective arthritis in women. This seems rather to throw the whole subject into the melting pot.

UTERINE HAEMORRHAGE.

IN a volume entitled *Uterine Haemorrhage* Dr. S. J. CAMERON and Dr. J. HEWITT of Glasgow have presented a full discussion of the various obstetrical and gynaecological conditions which cause this symptom. Their reason for so doing is that this one symptom, above all others in the whole range of obstetrics and gynaecology, should claim the attention of the general practitioner. The ample practical experience of the writers is enough in itself to vouch for the soundness of the teaching, which covers in systematic fashion the different conditions causing haemorrhage.

The obstetrical haemorrhages are discussed first—abortion and uterine moles, extrauterine pregnancy, ante- and post-partum haemorrhage, rupture of the uterus, lacerations of the cervix, and inversion. We were rather disappointed and surprised to find no mention of Hendry's method of controlling post-partum haemorrhage, which seemed, when his paper appeared, to be one of the most practical of recent contributions to this subject. The first chapter in the gynaecological section is devoted to the physiology of menstruation, and gives a very full and adequate account of the subject, although we have found no mention of the most recent work of Novak on the quantity of the endometrium which is shed monthly. The remaining chapters deal with the different gynaecological conditions of which

haemorrhage is the principal symptom, including the various forms of malignant disease, fibroids, endometritis, and chronic subinvolution. Under the treatment of the last-named condition there is no mention of the intra-uterine application of radium.

The volume concludes with an appendix upon the clinical manifestations of profound haemorrhage and shock, and a discussion of the technique of blood transfusion. It is written in a very readable style, and shows a wide familiarity with the literature of obstetrics and gynaecology. Our principal, and indeed only, difficulty about it is in regard to the advisability of writing a monograph upon a symptom. If this practice be followed to any great extent the output of literature will become even more overwhelming than it already is. The present book may be justified by the excellence of its substance, but on the whole we are inclined to think that the principle of it is in this respect unsound, and to hope that the example will not be followed.

HUMAN ANATOMY.

IN *Elements of Surface Anatomy*,⁴ by Assistant Professor MACLAREN THOMPSON of McGill University, we have a volume devoted to those parts of anatomy which can be studied from the surface, and which consequently are of special importance in diagnosis and treatment. The book does not differ much—naturally it cannot differ much—from other volumes devoted to the same subject, the only originality allowed being in the arrangement of the facts and in the choice of the nomenclature employed. The author covers the prescribed ground in some 170 pages, the text being divided into short paragraphs, in which the information given is not infrequently tabulated, thus facilitating reference and memorization. There are no illustrations. The nomenclature selected is that known as the B.N.A., the English equivalents for the terms, where the nomenclatures differ, being given in parentheses. The choice we regard as unfortunate from the point of view of the British student, who can scarcely, we think, be expected to welcome the substitution for such simple and adequate terms as "external and internal abdominal rings," of such pleonasms as "the subcutaneous (or superficial) inguinal (external abdominal) and the abdominal (or deep) inguinal (internal abdominal) rings"! The information in the book is, on the whole, full, accurate, and clearly expressed. A few relatively unimportant omissions and errors may, however, be noted. In the enumeration of the areas drained by the supraclavicular lymph glands the subdiaphragmatic area is ignored, while all that is said of the very important parotid group of lymph glands is that they lie in relation to the parotid salivary gland. The great sciatic nerve is stated, in agreement with so many other authors, to lie midway between the ischial tuberosity and the great trochanter, whereas its position is much nearer the former than the latter eminence. The tuberosity of the navicular (scaphoid), again, is not the most prominent landmark in the foot, the base of the fifth metatarsal having that distinction if we exclude the heel. The sternal angle (of Ludwig or Louis) is, of course, the angle of Louis, who was a French physician, not a German. Apart from such minor inexactitudes the volume is both reliable and attractive, and we have every confidence in recommending it, particularly to those of our readers who can readily adapt themselves, or who possibly have already adapted themselves, to a foreign nomenclature.

The fifth edition of SPALTEHOLZ's well known *Hand-Atlas of Human Anatomy*,⁵ translated from the original German by Professor LEWELLYS BARKER, seems to be a reprint pure and simple of the fourth edition, which was reviewed in the columns of this JOURNAL as recently as September 27th, 1924 (p. 578). The only differences to be noted are in such adventitious as the title-page and the prefaces, the former

⁴ *Elements of Surface Anatomy*. By I. MacLaren Thompson, B.Sc., M.B., Ch.B. Edin. Edinburgh: L. and S. Livingstone. 1925. (Cr. 8vo, pp. 172, 5s. 6d. net.)

⁵ *Hand-Atlas of Human Anatomy*. By Werner Spalteholz. Translated by Lewellys F. Barker. Fifth edition in English. In three volumes. London: J. B. Lippincott Company. 1925. (7 x 10: Vol. I, pp. 253, 331 plates; Vol. II, pp. 200, 231 figures; Vol. III, pp. 508, 432 figures. 24 net.)

² *Treatment of Gonococcal Infection by Diathermy*. By E. P. Cumberbatch, M.A., M.B., B.Ch.Oxon., M.R.C.P., and C. A. Robinson, M.B., London: W. Heinemann (Medical Books), 1925; 11 figures. 7s. 6d. net.
³ Samuel J. Cameron, M.B. Glas., F.R.F.P. (R.Glas.) London: Edward Arnold and Co. 1925; 1 figure. 8s. 6d. net.)

of which has been simplified while the latter have been suppressed. In the later edition the impressions of the blocks are perhaps a trifle sharper and the colour registration a trifle more accurate.

There can be no question as to the accuracy, completeness, and general excellence of the atlas, and we have every confidence in declaring it *facile princeps* in its own particular class. The only improvement we venture to suggest—and we do so with considerable hesitancy, for both as regards size and price the work should be kept within reasonable bounds—is the inclusion of a few representative transverse sections.

EVOLUTION.

PROFESSOR GRAHAM KERR's *Evolution*⁶ purports to be a book for beginners, intended to provide a sketch in outline, not overburdened with detail, of the evolutionary science of to-day. A book of this kind is badly needed, and Professor Kerr has supplied the want in a manner that leaves nothing to be desired. While the subject is treated in a thoroughly scientific spirit, it is presented in terms that should render it readily comprehensible to the laity. After giving a general idea of what evolution is, the author sets out to show that such a process has existed in nature. The proof is embodied in a series of chapters dealing severally with the embryology, palaeontology, comparative anatomy, and geographical distribution of animals, for the author confines himself to the animal kingdom as being his own province. Evidence of the existence of evolution having been adduced, the next step is to explain what conditions need to be postulated in order that the process of evolution may be conceived as possible—namely, the transmission of parental characters to the offspring, not in their completeness, but with a certain degree of variation. In this connexion the subject of heredity is fully discussed, including the significance of chromosomes, the statistical and experimental facts bearing on inheritance, and the Mendelian principle. The chapter on chromosomes, more particularly, contains matter of great interest, which will probably be new to most readers. Finally, there remained to be shown the manner in which evolutionary change has been brought about, and in dealing with this part of the subject the author has adopted, with some modification, the Darwinian theory of natural selection. This theory is, in some quarters, considered to be exploded, but it is pointed out that it never claimed to apply to any but natural, savage conditions, such as are to be met with in tropical regions; and the author asserts that no one who has had personal experience of the conditions of life in those regions will have the least doubt of the truth of the theory.

Having dealt with the phenomena of evolutionary change in its general aspects, the author turns to the application of the theory of evolution to man, both as an individual and in his communal relations. This part of the work contains a useful summary of knowledge of the fossil remains of man, and of his affinities with other members of the group of primates. The social development of man is necessarily touched upon very briefly, but it is made sufficiently clear that a citizen cannot be regarded as satisfactorily equipped, intellectually, unless he has a knowledge of the principles of evolution. Hitherto this knowledge can hardly be considered to have been necessary, for Nature succeeded, by somewhat ruthless methods to be sure, in producing a fine type of individual without any essential co-operation on his part. Now, however, when civilization is incessantly thwarting Nature's methods, the type of individual developed will depend more and more on the policy of the individual himself. To mention one point only in which a knowledge of the subject may be serviceable to the citizen, it will impress him with the extraordinary adaptability of the individual to his environment. If the latter is such as to favour a low type that type will assuredly emerge, whatever hopes may be entertained to the contrary. Unconsciously he will seek to define what is meant by high and low types, and be led to inquire how some of the more notable modern innovations—such

as the cinema and gramophone, contraceptives and the dolo—stand in relation to them. The man who is imbued with the principles of evolution will probably attach more importance to character and bearing than to such things as making a fortune or having a good time.

CANCER OF THE RECTUM.

IN 1923 Mr. ERNEST MILES, senior surgeon to the Cancer Hospital, delivered the Lettsomian Lectures before the Medical Society of London, and he has now printed them in a little book entitled *Cancer of the Rectum*.⁷ At the time of delivery these lectures were greatly appreciated because of their clear account of the pathology and surgical treatment of rectal cancer. Nothing fresh has been added to the lectures since they were spoken, and no attempt has been made by the author to comment on the opinions and practices of other surgeons. They have therefore an individualistic tone. The two particular subjects on which Mr. Miles can speak with the authority of the pioneer—namely, on the lymphatic spread of cancer of the rectum and the abdomino-perineal operation—are both set forth very clearly in these three lectures. A description of the spread of cancer through direct continuity of tissue, by way of the venous system, and by means of the lymphatic system, forms most of the substance of the first chapter, and is illustrated by a number of diagrams and photographs. Nearly all of the third and last lecture is devoted to the radical abdomino-perineal operation, which is described in all its stages and backed by strong arguments based on knowledge gained from pathological researches. The fifty illustrations of this little book are very useful—particularly, perhaps, the schematic representations of the lymphatic system.

NOTES ON BOOKS.

THE first edition of Dr. CAMMIDGE's handbook *The Insulin Treatment of Diabetes Mellitus* was reviewed in these columns soon after it appeared (BRITISH MEDICAL JOURNAL, February 23rd, 1924, p. 325). The book was out of print for a short time, but a second edition⁸ has been issued, and the opportunity has been taken by the author to bring the subject-matter up to date by adding a summary of the advances made in the experimental investigation of insulin and its uses in clinical medicine since the first text was written.

English readers will be glad to know that the English translation of the second volume by Professor HAAS has been made by Mr. T. VERSCHOYLE and published with the title *Introduction to Theoretical Physics*.⁹ In this volume the distinguished Viennese professor of physics deals with the atomic theory, the theory of heat, and the theory of relativity. The book is translated from the German third and fourth editions, and in the period since these were published rapid advances have been made in atomic theory and in the experimental researches upon which it is based. Professor Haas has supplied a brief summary of the more important work carried out between the publication of the German edition and the present English edition of volume ii. This summary has been placed under the heading of addenda, and the reader's attention is drawn to this new matter by asterisks. We called attention to the first volume of this authoritative work when it appeared (BRITISH MEDICAL JOURNAL, April 18th, 1925, p. 745).

THORPE and WHITELEY's *Manual of Organic Chemical Analysis*¹⁰ is a well prepared volume of instruction in qualitative recognition and quantitative determination of organic substances. The practical recognition of organic substances is the source at first of a good deal of perplexity to the student of organic chemistry. All attempts to frame an ordered plan of examination come inevitably to an end at an early stage in the scheme of directions. The branches in the lines of search

⁷ *Cancer of the Rectum*. By Ernest W. Miles, F.R.C.S. London: Harrison and Sons, Ltd. 1925. (Demy 8vo, pp. viii + 72; 50 figures. 7s. 6d. net.)

⁸ *The Insulin Treatment of Diabetes Mellitus*. By P. J. Cammidge, M.D. (Lond.), D.P.H. (Camb.). Second edition. Edinburgh: E. and S. Livingstone, 1924. (Cr. 8vo, pp. viii + 216; 51 figures. 6s. net.)

⁹ *Introduction to Theoretical Physics*. Vol. II. By Arthur Haas, Ph.D. Translated by T. Verschoyle, M.C., B.Sc., A.R.C.S. London: Constable and Co., Ltd. 1925. (Demy 8vo, pp. x + 414; 130 figures, 2 plates. 21s. net.)

¹⁰ *A Student's Manual of Organic Chemical Analysis: Qualitative and Quantitative*. carbohydrate by means of simple addition. Each card contains five columns giving the name of the food and the quantity in ounces, and the remaining columns give the content of protein, fat, and carbohydrate in grams and the calorie value. The idea is extremely simple, and a box of cards containing details of more than sixty foodstuffs costs 2s. 8d. It can be obtained from Messrs. David Challen, Ltd., 10, City Road, London, E.C.1.

Pure Thyroxin.

We must congratulate the British Drug Houses on their enterprise and skill in preparing pure thyroxin on the commercial scale. An impure product has been on the market in the form of tablets, but it has been offered at almost prohibitive prices. A pure product—(sodium salt of pure thyroxin B.D.H.) is now available at a rate equivalent to £11 5s. a gram. This represents a very great reduction on previous prices. The dosage of thyroxin ranges from 0.2 to 2 mg. a day, and the cost from a penny to sixpence a day. The activity of preparations of dried thyroid varies greatly, and unfortunately no reliable method of standardization has yet been devised. Pure thyroxin B.D.H. consists of a chemically pure substance of known activity, and the price places it within the reach of everybody. This preparation should prove of great utility in the treatment of hypothyroidism.

MEDICAL PROGRESS IN MALAYA.

KING EDWARD VII COLLEGE OF MEDICINE AT SINGAPORE.

THE annual meeting in February, at Singapore, of the Malaya Branch of the British Medical Association was of special interest since it was held in the new King Edward VII College of Medicine, which was formally opened by the Governor, Sir Laurence Guillemard, during the proceedings. As we mentioned on December 1st, 1923 (p. 1060), the foundation stone of the new college was laid during the fifth congress of the Far Eastern Association of Tropical Medicine in Singapore, in September, 1923. The old college was founded in 1905, and in 1916 its diploma was recognized by the General Medical Council as a registrable qualification.

After the ceremony of opening the college, the principal, Dr. G. H. K. Macalister, read a message of cordial congratulation from Sir Humphry Rolleston, and recounted the ideals of medical training and research which would enable the college to become a great asset to the whole of Malaya. Sir Laurence Guillemard described the origin of the college, which, though a Government institution, had at its foundation received generous support from Chinese citizens; among its benefactors also were the King Edward VII Memorial Fund Committee and the Rockefeller Foundation. During the previous month the college had received visitors from far distant lands, including Brazil, Gibraltar, New York, Manchuria, Sydney, and Tokyo. The establishment in Singapore of the Eastern Bureau of the Health Section of the League of Nations would provide a great incentive to the study of hygiene in the college. The Governor pointed out how visitors to Singapore on entering the harbour would see a group of commanding buildings, at the heart of which were the classic columns of the College of Medicine. Singapore contained no other example of the pure school of classical architecture, and the choice of design was appropriate in that it symbolized the strength of the bond between modern medicine and the ancient philosophy of Athens, giving expression to the reverence paid to the endowment of wisdom handed down through the ages.

The Governor then presented the three first honorary diplomas of the college to three past presidents of the Malaya Branch: Sir David Galloway, who for forty years had been prominent in public health work and the municipal government of Singapore; Dr. Lim Boon Keng, who was for many years lecturer on materia medica and therapeutics in the college, and became in 1921 president of the Amoy University; and Sir Malcolm Watson, a medical officer of the Federated Malay States, who was renowned throughout the world for his work in the prevention of malaria.

Dr. A. L. Hoops, the president of the college council, and of the Malaya Branch for the current year, thanked the Governor and Lady Guillemard for their attendance, and explained how Chinese support had made possible the foundation of the college on its present scale. The professorship of physiology was founded mainly by Chinese subscribers in memory of King Edward VII, and the

building for the anatomy department was presented by a Chinese benefactor. There were now nine whole-time professors paid entirely by the college; those who were clinicians had charge of their respective specialties in the Government hospitals. In addition to the whole-time staff there were fifteen part-time lecturers. The medical course occupied six years, and the licentiates were free to practise throughout the British Empire.

Annual Meeting of the Malaya Branch.

At the annual meeting of the Malaya Branch, Dr. A. L. Hoops, principal civil medical officer for the Straits Settlements, was elected president, and Dr. J. W. Scharff honorary secretary. The retiring president, Dr. A. R. Wellington, described the activities of the Branch during the past year, Sir David Galloway delivered an address on anomalies in the course of congenital syphilis in Chinese; Dr. A. Neave Kingsbury read a paper on the prophylaxis of measles, Dr. M. J. Ratray dealt with notification of venereal diseases in males, with reference to co-ordinating treatment in different ports, and Mr. A. Dickson Wright read a paper on lymphuria. A visit was paid to the new Singapore General Hospital, where clinical demonstrations were given. Surgeon-Commander D. H. C. Niven arranged a microscopic demonstration of culicine mosquitos and their larvae found on Singapore island. An excursion was made to Gunong Pulai, where Dr. Hunter gave an account of the successful drainage work that had been undertaken to combat malaria among the labour force. The social part of the programme included the competition for the Watson golf cup, which was won by Dr. Hunter, and the annual dinner and dance.

The Origin of Western Medicine in Japan.

Dr. A. L. Hoops, in his presidential address to the Malaya Branch, described the progress of Western medicine in Japan since it had been introduced in 1549 by Luis Almeida of the company of Francis Xavier, who established charity institutions for the care of lepers, orphans, and the indigent sick. He was followed by Portuguese priests, who introduced medicinal plants and taught medicine, but later in the century severe restrictions against Christianity were imposed and many Portuguese and native medical practitioners were put to death. The Japanese, however, kept the lamp of medical science burning, and at the beginning of the seventeenth century the Dutch obtained a concession in Japan, the medical department of which enabled Western surgery to be learnt by the Japanese. Dr. Hoops mentioned that the book of Ambroise Paré had been translated into Japanese early in the eighteenth century, and that the first necropsy was performed in 1777. Up to that date it had been believed that the viscera of the European barbarians were transposed, and that only those of the Japanese and Chinese were arranged normally. The foundation of a school of Dutch learning followed at Narutaki in 1825; by it various Western instruments, such as the clinical thermometer and stethoscope, were introduced. In 1857 the first permanent medical school was founded in Tokyo; it was the precursor of the Medical Faculty of the Imperial University. English medical science had played only a minor part in Japan up to the middle of the nineteenth century, but in 1867 a British physician, Willis, was appointed instructor in the Tokyo Medical College and director of the hospital. He was replaced by German teachers in 1871, but continued to teach in Satsuma. Japan quickly acquired a knowledge of Western medical science, and since 1900 all the teaching posts in medical schools had been filled by Japanese. There were now twenty-seven medical schools in Japan, of which eighteen were of University standing; two schools were for women alone. Dr. Hoops gave a detailed account of modern laboratory research in Japan, with especial reference to the work of Kitasato and Shiga. The investigation of nutritional problems had now been made an independent branch of medical science, and a Government Institute had been established in 1920 for research into foodstuffs and a scientific study of nutrition. Dr. Hoops concluded with an account of the present hospital system in Japan, and of the general sanitary administration, including preventive work.

British Medical Journal.

SATURDAY, APRIL 3RD, 1926.

LONDON UNIVERSITY SITE.

THE Treasury has given notice to the Duke of Bedford that he is free to resume possession of the site in Bloomsbury which it had agreed with him in January, 1921, to purchase under conditions which restricted its use to university and college buildings in connexion with the University of London. This offer to return is in accordance with the strict terms of the original conveyance, and the Duke has six months to decide whether or not he will accept it. The Senate of the University does not, evidently, consider the Treasury's decision final; it seems, indeed, to be somewhat startled by its ruthlessness; possibly that was the reason why the Treasury wrote to the Senate in the terms it did on March 23rd. As soon as it learnt from the Treasury letter of March 23rd what had happened—namely, "that the Lord Commissioners of the Treasury have actually offered the Bloomsbury site for resale to the vendor"—the Senate wrote off to the Treasury (on March 24th) expressing the hope that "the Treasury will take such steps as are now practicable to secure the retention of as large a part as possible of the site for University purposes." It is therefore to be concluded that the Senate has decided that it would be to the advantage of the University to move to the Bloomsbury site.

The delay in coming to a decision has undoubtedly been very great, for Mr. H. A. L. Fisher, the then President of the Board of Education, offered the site on April 7th, 1920. The Senate has now issued a memorandum to the press explaining how the delay of nearly six years has come about. It is an interesting document, and appears to prove that the Senate itself has been little, if at all, to blame for the delay, which had its origin in a slight difference between the Government's bargain with the Duke of Bedford and the offer made by Mr. Fisher to the University. The agreement with the Duke of Bedford was that the site should be used only for university and college buildings in connexion with the University of London.¹ The offer of Mr. Fisher was that the site was to be used "for new headquarters of the University and for colleges and institutions connected with it, including King's College." The Senate interpreted this to mean that the movement of King's College from its existing site in the Strand to Bloomsbury was an absolute condition of the offer. King's College took four years and a half to make up its mind, and even then the communication it addressed to the Senate was not in itself an absolute refusal to move; it indicated that it was reluctant to move, and asked certain questions as to finance, by which its action was finally to be determined. The communication from King's College was at once (December 18th, 1924) sent to the Treasury. No reply having been received from the Treasury by May 13th, 1925, a reminder was sent on that day, and on June 3rd the Treasury replied that it was not

without hope that it would be possible to make arrangements with the vendors whereby at least a part of the site might be occupied for other university purposes. To this the Senate replied that as the only conditions upon which King's College would move were not to be fulfilled, and since the offer made to the University was conditional upon King's moving, the University could not accept that offer. On October 27th, 1925, the Senate again wrote to the Treasury asking whether it would consider suggestions for the occupation of the whole or part of the Bloomsbury site for the central offices of the University or other university purposes. The Treasury did not reply, and on March 1st, 1926, the Senate wrote again, and then received in reply the bombshell to the effect that the Bloomsbury site had already been offered back to the Duke of Bedford, "no effective scheme for the utilization of the site having been matured during the five years which have elapsed since the purchase." The Treasury, however, still shows reluctance to abandon the Bloomsbury site altogether. The Senate had suggested on March 1st last that a conference should be held between representatives of the Treasury and of the University, and in its letter of March 23rd the Treasury said that "it would be glad to consider any representations or to examine any proposals which the Senate of the University may desire, either in writing or, if preferred, at a conference." In reply the Senate has notified the Treasury that it has appointed six persons, in addition to the official members, to confer with the Government on the general situation in accordance with its suggestion. The persons selected by the Senate, in addition to the official members, are Sir William Beveridge, Sir William Collins, Professor Filon, Dr. Graham Little, M.P., Sir Josiah Stamp, and Sir Holburt Waring. That, as far as we can ascertain, is the position at the present moment. The Senate still awaits the reply of the Treasury to the offer of a conference, and we can only hope that the reply will not be long delayed.

The Senate's memorandum, to which we have already referred, concludes as follows: "The Bloomsbury site cannot be used within the narrow terms of the original offer made by the Government to the Senate, since that implied moving King's College, but it is clear that the site can be effectively used for 'University and College buildings in connexion with the University of London' within the much wider terms of the agreement between the Government and the Duke of Bedford. Nothing, in fact, is more certain than that the whole of the area now in question can be fully utilized for these purposes. If this area is now lost to education, it or more expensive land in the same neighbourhood or near by will have to be acquired again later, bit by bit, by the University or its Colleges." The Senate, therefore, appears to have come round completely to the opinion that the University ought to move to the Bloomsbury site, an opinion which has been held all along by a large proportion of those interested in the future of university education in London.

A NEW CONCEPTION OF THE THYROID GLAND.

NOTHING could have been more simple than the structural conception of the thyroid gland imparted to students by teachers of a former generation. It was made up of minute vesicles, each about one-hundredth of an inch in diameter, lined with a cubical epithelium, and filled with a colloid secretion. The conception of

¹ The site is a British Museum to other side of which Russell and Woburn runs north and south, and is situated by Mr. Fisher's surveyor of 83 or Square were or we roads. Its north is British Medical Association.

the north end of the ringite Church, on the eastern side abuts on in Mallet Street, which of Gower Street. It was by the county council gardens of Torrington estimate included the the new House of the

the thyroid now being taught by Dr. G. Scott Williamson,¹ and supported by an array of observations drawn from glands in all stages of growth and in all states of activity, is that it is made up, like the liver, of an enormous number of minute units or lobules, each about one-twenty-fifth of an inch in diameter. But whereas each hepatic lobule is embedded within a venous or blood sinusoid, the thyroid lobule lies within a lymph space or sinusoid. The thyroid gland is thus planted on the lymph system, a relationship which Mr. R. H. Burne has demonstrated in the anatomy of the angler fish. Each lobule or unit of the thyroid has its own hilum, its own delicate capsule, lined by lymphatic endothelium. Each lobule, during its active phase, has its thyroid epithelium arranged in convoluted cylinders; the cells of each cylinder are grouped round a lumen, and are surrounded by capillaries and enclosed by a covering of lymphatic endothelium. The output of a lobule in the phase of active secretion appears within the lumen of the cylinder, and Dr. Williamson is convinced that he has traced its passage into the lymph space surrounding the cylinder, and that it is through the lymph system that the secretion, which in the active phase is clear and watery, passes out into the general circulation of the body.

Such is Dr. Williamson's picture of a lobule or gland unit in a state of activity—a state which may be seen throughout the gland at birth, in the years of adolescence, in pregnancy, and in Graves's disease. In some stages of growth, as in children under the age of 5, most of the lobules or gland units pursue another form of activity. A colloidal substance, which Dr. Williamson regards as altogether different in nature from the clear secretion of the active phase, collects in the lumina of the cylinders; the cylinders become broken up, and produce the vesicles with which all are familiar. No new light is thrown on the manner in which the colloid content of the vesicles is formed; apparently it passes into the blood capillaries which surround the vesicles, and thus is carried by the blood to the tissues of the body. Dr. Williamson presumes that the vesicles may become abnormally distended, either through a too rapid formation of colloid or by a failure in the rate of its absorption. The mechanism which causes one lobule to pass into a state of active secretion while a neighbouring lobule applies itself to the storage of colloid is not known; but Dr. Williamson is of opinion that the tissues of the body have some means of making their wants known to the thyroid and of evoking a direct response from it. However this may be, the solid fact remains that in endemic goitre of the vesicular type—where colloid storage has been carried to an excess—iodine medication is effective, whereas in the hyperplastic or secretory types of goitre, as in secondary Graves's disease, iodine medication is useless or even injurious. Also another result emerges—namely, that when we have to interpret the pathological appearances presented by the thyroid gland we obtain no guidance from the old teaching of thyroid structure, whereas Dr. Williamson's observations give us the key to a rational interpretation.

In drawing inferences as to a direct functional relationship of the thyroid to the parathyroids, and of both to the thymus, Dr. Williamson enters a field of bold speculation, and yet one which is justified in the present state of our knowledge. The lymphatic systems of the thyroid and thymus are certainly in

close union; thyroid and thymus have a similar origin in the embryo, and it may be that the endothelial cells of the thymus store and disseminate substances formed by the epithelium of the thyroid. Much has to be done before such speculations can be seriously entertained. But of this we may rest assured: the method of inquiry pursued by Dr. Williamson has much to commend it. He has broken down the barriers that lie between anatomist, physiologist, and pathologist. In his inquiry into the disorders of the thyroid he has played the triple part of anatomist, physiologist, and pathologist, and each department of his inquiry has helped the other. His research is one of the many benefits which have flowed to medicine through the wise encouragement and support of the Medical Research Council.

VOCATIONAL GUIDANCE.

An interesting research, undertaken by the Industrial Fatigue Research Board and the National Institute of Industrial Psychology, on the subject of vocational guidance¹ has been published this week by the Medical Research Council. A corps of expert workers was gathered under the direction of Professor Cyril Burt, and as a preliminary step an analysis of the occupations taken up by 1,000 children leaving the schools in a London borough was made. The investigation proper consisted in an intensive study of all the children due to leave three schools in this borough in the course of the next year, and of making vocational recommendations based on this study. After a lapse of two years as many as possible of those who had been tested were traced, and the successes and failures noted and related to the indications of the tests. The range of occupations available was wide, ranging from professional work to van boys. In the specific investigation of the children inquiry was made into the following points: home conditions; physical state; mental conditions (both for general intelligence and special capacities); educational attainments; special interests; and finally temperament and character as shown by emotional, moral, and social qualities. The vocation indicated was thereon assigned to the particular child. The selected children numbered 100; the highest mental ratio was 134, the lowest 62, the individual rate of intelligence being scattered over a range of more than nine mental years. A modification of the Stanford revision of the Binet-Simon tests was used. The time occupied in testing each child was thirty to forty-five minutes. A high correlation between the tests and the teachers' ranking was found. In making the choice of occupation for the child the tabulated list of occupations (which is given in full) was found to be of great value. A full account of the tests employed is given. Boys and girls were in nearly equal numbers. Girls gained higher marks in decidedly linguistic questions; boys were easily first in their account of an invention. Home conditions proved to be superior in 14 cases, good in 34, moderate in 32, poor in 16. There was a close correlation between home conditions, parental intelligence, and the mental ratio of the children; both the latter were highest in the superior homes and lowest in the poor homes. Physical conditions were in general far less important than mental; only exceptionally did such data bear directly upon the choice of occupation, and then the inference was rather negative than positive—for example, the child with hypermetropia or astigmatism was advised not to take to work involving eye-strain, such as needlework. Speech defect contraindicated such work as that of shop assistant. Laundry girls must have strong arms; and the aspirant to the finest needlework must have dry hands. The 100 children were

¹ The Applied Anatomy and Physiology of the Thyroid Apparatus, *Brit. Journ. Surg.*, 1926, vol. xiii, pp. 456-458. Dr. Innes Pearce collaborated with Dr. Williamson in this and other published researches on the thyroid.

¹ A Study in Vocational Guidance. Medical Research Council. London: H.M. Stationery Office, 1925. (Pp. 169. Price 4s. net.)

marked out for fifty different occupations; thereupon a letter was sent to the parents stating the occupation recommended, with possible alternatives, and giving reasons. In 47 an occupation was recommended different from that suggested by parents or teachers; in 35 the recommendations from both sources were the same. The suggestions of parents and teachers were apt to be vague, but the tests and the intensive examination led to suggestions that were quite specific. After the lapse of two years the homes of each of the children were revisited. Six could not be traced; only 2 were out of work; 25 were engaged in unskilled work, 35 in semi-skilled work, and 26 in skilled work; 6 fell into the category designated above as highly skilled. The general outcome of the inquiry is held to speak strongly in favour of the methods used. Judged by the after-histories of the several children, those who entered occupations of the kind recommended have proved both efficient and contented in their work. As compared with their fellows they are, on an average, in receipt of higher pay; they have generally obtained promotion earlier; they have experienced fewer changes of situation; and very few indeed have incurred dismissal. Over 80 per cent. declare themselves satisfied alike with the work they have taken, their prospects, and their pay. On the other hand, of those who obtained employment different from the kind advised, less than 40 per cent. are satisfied. Among the latter group nearly half dislike their work; and among the former only one dislikes it, and that simply because it is not identical with what was originally suggested. Though no great weight must be attached to figures from so small a group, yet the results are considered to be encouraging. It is hoped to continue observation on these particular children, and also to extend the inquiry to secondary and other types of schools.

CHRONIC ARTHRITIS AND ITS ETIOLOGICAL ASSOCIATIONS.

ALTHOUGH general opinion is to the effect that at least the vast majority of cases of what is commonly called chronic rheumatoid arthritis are infective in origin, there is wisdom in the reservation that after all this may not be universally true. For not only are there many cases in which an exhaustive, and indeed sometimes an expensive, search fails to find an infective focus, but there is good evidence of the existence of toxic forms of arthritis and synovitis in gout and serum sickness, and probably in the rare condition of intermittent hydrarthrosis. Whether or not in rheumatoid arthritis and osteo-arthritis errors of metabolism, such as may be due to endocrine disorders, do more than favour infection is open to philosophic doubt, and any further light on this difficult problem is therefore welcome. In a paper published in this issue (p. 612) Drs. E. P. Cumberbatch and C. A. Robinson have reported cases in women of arthritis, without any evidence of infection, coming on about the onset and cessation of menstruation and so at periods of changes in ovarian function. These patients are described as being much benefited by diathermy of the ovaries, and it is definitely suggested that the rationale of the treatment is to correct deficiency of an ovarian hormone. This no doubt is a rather speculative explanation, but it deserves investigation and consideration in virtue of the practical success reported, even though it may prove to be empirical only. Diabetes mellitus is an outstanding example of disordered metabolism of endocrine origin, and so the question of arthritis associated with it may not be without interest in this connexion. In a number of papers Ralph Pemberton has considered the relation between carbohydrate metabolism and chronic arthritis, and found that a restricted carbohydrate diet benefited chronic arthritic patients even though a septic focus was present. The old view that sugar is bad for

rheumatism was also shown to be correlated in the majority of cases with a lowered sugar tolerance which roughly was proportional to the activity of the arthritis. As diabetics are subjected to such a diet for long periods, he thus explained their comparative freedom from arthritis as shown by his experience and by that of F. M. Allen and of Elliott P. Joslin. It is therefore interesting to note Schmitt and Adams's figures¹ given from the Mayo Clinic, which are of a rather different complexion: during 1925, among the 474 well defined but as a rule comparatively mild diabetic patients in the clinic, 51 had arthritis, usually of the so-called hypertrophic type and not of a kind in any way peculiar to diabetes. Besides being on a restricted carbohydrate diet they had the ordinary methods of treatment for arthritis. There was not any noticeable difference in the results between the ordinary run of cases treated by the usual methods alone and the diabetic arthritics who in addition were on a restricted carbohydrate dietary.

THE ECONOMICS OF RECOVERY HOMES.

THE economics of the recovery home or auxiliary hospital as an alternative to an increase of ward accommodation on the main hospital site were debated at a meeting of the Incorporated Association of Hospital Officers on March 19th. A recovery home, it should be explained, is not a convalescent home; it is an establishment, preferably in the country or at the seaside, for patients who no longer need the specialized treatments available in the ordinary wards, but are not well enough to be discharged even to a convalescent home. About three years ago a committee of the King Edward's Hospital Fund for London considered the question of recovery homes in connexion with hospitals, and visited all such homes in the neighbourhood of London. The committee came to the conclusion that, while recovery homes were excellent institutions from the point of view of the comfort of the patient, their effect in reducing hospital costs on the basis of each occupied bed was no greater than would be achieved by adding an equivalent number of beds on the hospital site. Last year a memorandum expressing a different view was published by Dr. F. N. Kay Menzies and Mr. R. H. P. Orde,² who argued that recovery homes were an economic and financial advantage to the hospital, as well as being, as everyone admits, of value to the patients concerned. At the recent meeting of the Association of Hospital Officers a reply to this memorandum was made by Mr. H. R. Maynard, secretary of the King's Fund, who, in an elaborate exposition of hospital costing, claimed to disprove the view that to segregate "recovery patients" in separate homes is inherently cheaper than extension at the hospital site. It would be difficult in a short space to follow Mr. Maynard through his maze of figures, but he advanced illustrations to show that the financial and economic effects of extending a hospital on its site and of establishing recovery homes elsewhere were approximately the same. He warmly approved recovery homes, but thought that their advocacy should be based on the ground of real advantage to the patient, and not on that of some phantom saving of costs or some supposed addition to the number of patients who could be more economically treated for the same number of beds. One or two hospital secretaries supported Mr. Maynard's conclusions. Mr. G. G. Panter, of the Royal Northern, said that for the last ten years there had been attached to his hospital both a recovery home and a convalescent home. The purpose of these homes was to expedite recovery of the patients who were accommodated in them, more particularly by stimulating in them the will

¹ Schmitt, E. O. G., and Adams, S. F.: *Journ. Amer. Med. Assoc.*, Chicago, 1926, lxxv, 535.

² *BRITISH MEDICAL JOURNAL*, September 26th, 1925, p. 576

to recover, and to free the ordinary wards of those cases for which the special equipment available in those wards was no longer necessary. In his experience the best proportion of recovery beds to hospital beds proper was 35 or 40 to 100. Since the home of recovery had been started in connexion with his own hospital it had been possible to reduce the total length of stay in hospital by three days on the average. He was of opinion, moreover, that there must be some little saving of cost by the use of a recovery home. Mr. Orde, one of the authors of the memorandum to which Mr. Maynard's paper was a reply, repeated his contention that even from the economic and financial point of view recovery homes were advantageous. He said it was not unusual in the ordinary wards of a hospital to find that 15 per cent. of the patients did not require the specialized treatment which the ward provided. It could never be an economic proposition to add beds to the parent hospital and utilize them for the retention of patients a moment longer than was absolutely necessary. Where recovery homes had been possible in connexion with a hospital it had been found that the combined cost of each occupied bed in the whole institution—the hospital itself and the recovery home together—was nearly £3 a year lower than in the parent hospital alone. Sir Arthur Stanley, in closing the discussion, said there could be no doubt that the real value of recovery homes was to the patients themselves, whether or not any considerable saving of costs was effected for the hospital.

MENTALLY DEFECTIVE OFFENDERS.

THE Prison Commissioners have paid acknowledgement on previous occasions to the very great benefits conferred on the community by the Mental Deficiency Act of 1913. This acknowledgement is again made in their recently issued report¹ for the year 1925-26. They instance the fact that during the past four years close on a thousand mentally defective offenders were dealt with under the provisions of this Act, and sent to institutions; the result being the depletion of the ranks of the habitual offenders to that extent and the prevention of a considerable amount of crime. There are two considerations, however, which cause the Commissioners to temper their acknowledgement with criticism. The first of these is the difficulty frequently encountered by medical men in obtaining definite information of the early life of the defective. Very often such information is withheld by the parents. The Act stipulates that the mental defect must be shown to have existed since birth or from early age; and the absence of the definite knowledge of this makes it impossible to certify certain cases of undoubted mental defect, and cases in which the need of care and control is urgent. The Commissioners strongly favour some amendment of the Act so as to enable medical men to give a certificate in cases of mental defect just as they do in cases of insanity—that is, upon the facts of the present condition, and without reference to past facts. The second consideration arises from the presence of a considerable number of offenders who are definitely subnormal and mentally unstable, but who are not certifiable under the Mental Deficiency Act. They are unfit for prison discipline, and are injuriously affected by that environment. They need special care and curative treatment, and the Commissioners are of opinion that if it be thought too strong a measure to make them certifiable as mental defectives, it should at any rate be possible to place them under suitable control when they have come in conflict with the law. The medical officer of Brixton Prison reports that those cases which are found to be defective and yet which are not certifiable far outnumber those who

have been certified. He also draws attention to another class of offender for which adequate provision is not made. This class comprises the mildly senile and other cases of dementia, who commit trifling offences, often because they are unable to earn a living. They are not certifiable as insane, and yet are not able properly to look after themselves. Compulsory detention in the workhouse or infirmary is suggested as the best means of dealing with such cases. During the year, 1,523 men and 490 women were remanded to prison for mental observation and report. Dr. G. B. Griffiths, the Medical Commissioner, points out that there is never any difficulty in obtaining a medical report if the person is remanded for the purpose, and that there is no reason for the practice of some benches of justices of convicting prisoners and sending them to prison requesting observation on their mental condition. The medical officer of Birmingham Prison is not satisfied that a sufficient number of cases are remanded for mental examination. Only a particular type of case is at present so remanded, and he urges the necessity of psychological examination in a much larger number of cases. His point is that only in this way can the existence of mental abnormality be detected. He considers that the whole question of the correct treatment of offenders is a purely psychological matter, and it is because he regards society as being most inadequately protected by our present methods that he presses for this change. At present the performance of routine duties in a large prison leaves only too little time for essential psychological investigation. During the year 97 prisoners undergoing sentences in local prisons were certified insane (84 men and 13 women). The corresponding figures for 1923-24 were 98 (81 men and 17 women). Besides these, 191 men and 46 women were found by the prison medical officers to be insane while on remand or awaiting trial; 14 men and 6 women were found by juries to be insane on arraignment, and 13 men and 8 women "guilty but insane."

HEALTH OF HONG-KONG.

WE gather from the report of the medical department for the year 1924 that Hong-Kong is a healthy colony. The year was free from any serious outbreak of infectious disease, although the small-pox epidemic of 1923 overlapped into the early months of the year under review. For the first time for many years the colony was entirely free from plague. Beri-beri was prevalent, and in one gaol 200 of the prisoners showed some signs of the disease. The rice supplied to this prison showed a percentage of phosphorus pentoxide well above the standard which is considered safe. At the same time the prison was overcrowded; and when this overcrowding was remedied the trouble subsided without any alteration in the diet. Many of the policemen recruited from Wei-hai-wei suffered severely from malaria. There were no fewer than 591 admissions to hospital for this disease during 1924 from a force of 275 men. In the statistics of the Tung Wah Hospital, Victoria, a considerable decrease in admissions is noted. The decrease was due to admission being refused to patients who were suffering from destitution and general debility rather than from any recognized disease. No case of scarlet fever was treated at this hospital; and it appears that the Cantonese are almost, if not "quite," immune to this disease. As Europeans suffer from scarlet fever in Hong-Kong the immunity is regarded as racial and not regional. The Chinaman's appendix vermiformis seems less vulnerable than the European's, possibly owing to the differences in diet; but the principal civil medical officer suggests that the endocrinologist will attribute the infrequency of appendicitis to thymic differences in the races. The only complaint we have to make about

¹ Cmd. 2597. H.M. Stationery Office. Price 1s. 3d.

this report and many others of the same kind is that no indication of the country to which it applies is given on the title-page, beyond the address of the firm which printed it.

OPHTHALMIC HOSPITAL OF THE ORDER OF ST. JOHN OF JERUSALEM.

THE recent visit to Palestine of the Sub-Prior and Knights of the Order of St. John of Jerusalem in England has directed attention to the Ophthalmic Hospital of the Order, in Jerusalem, which has for many years won the deep gratitude of the various nationalities composing the population of the city and the surrounding country. No national, political, or religious propaganda work is associated with the hospital, but its beneficent activity proceeds in such an unostentatious way that many of those making use of it are unaware that any special nation or creed is concerned in its management. A valuable and striking manifestation of the local appreciation was given when free permission was granted to the members of the Order to visit the Dome of the Rock and explore certain historical sites which have hitherto been frequently barred to others than Moslems. As a closing incident of the celebrations in Jerusalem the Sub-Prior held a reception at the hospital, and the numerous improvements effected, particularly during the last year, were demonstrated. The thirty-fourth report of the committee of the Ophthalmic Hospital, which has just been issued, contains the information that during 1925 the number of new out-patients increased from 16,225 in 1924 to 16,640; the total attendances from 75,560 to 81,495; and operations from 4,283 to 4,407. The in-patients numbered 1,527, as compared with 1,676 in the previous year, which is explained by the temporary closing of the operating theatre and the wards for cleaning and re-decorating, and the increased performance of trichiasis operations in the out-patient department; the in-patient accommodation was, therefore, used for intraocular cases requiring longer stay in the hospital. The water famine in Jerusalem from January till April demonstrated the value of the two cisterns in the hospital, since the town supply was only available for two hours each day, and even then was far from satisfactory. The outstanding event of the year was the installation of electric light and power in the hospital, all the equipment being British-made. The x-ray equipment was in working order in September, and a new sterilizer was presented by Canadian sympathizers. A giant magnet for the extraction of metallic fragments from the eye is being supplied by other supporters, and an American visitor has promised to give a slit-lamp; in consequence of the receipt of an anonymous donation the building of a new annexe for cases of acute infectious conjunctivitis will be facilitated. As we mentioned on February 13th (p. 295), the warden of the hospital is in charge of the establishment of ophthalmic clinics throughout Palestine, the Order undertaking the responsibility of posting nurses at six of the twelve clinics. One of these clinics is at Acre, and thus, after the lapse of 735 years, the Order is again established in its last crusading stronghold in the Holy Land. The report of the warden, Lieut.-Colonel J. C. Strathearn, M.D., contains numerous details of clinical interest. An analysis of the causes of blindness showed that 30 per cent. was due to secondary glaucoma; 22 per cent. to totally opaque cornea; 19 per cent. to shrunken globe; 14 per cent. to different types of cataract; 7 per cent. to disease of the uvea, retina, or optic nerve; 6 per cent. to chronic glaucoma; and 2 per cent. to injury and other causes. Thus in more than 70 per cent. of the cases blindness was traceable directly or indirectly to acute conjunctivitis which, if taken in time, could have been successfully treated. Trachoma was recorded in 87 per cent. of the patients, and 2,854 operations were performed for trichiasis and

entropion, which in Palestine result almost invariably from trachoma. The warden mentions the training of Government medical officers in the essentials of ophthalmology, which is being undertaken; nine have already received a practical course of six weeks' duration. The training of nurses is also being actively carried on.

BRITISH SPA FEDERATION.

ALL the leading spas of Britain were represented at the recent annual meeting in London of the British Spa Federation. There were discussions on the steps taken to meet the competition of the foreign resorts. No definite evidence was forthcoming at the meeting that the foreign spas offered any advantages over the British resorts except their alleged cheapness owing to the abnormal rate of exchange. Disappointment was expressed at the small amount of encouragement offered by the railway companies to visit the home health and pleasure resorts. The lack of inducement to travel in Britain, especially in the winter and spring, when it might be supposed that increased passenger traffic would be welcomed by all companies, compared with the cheap tickets issued to the Continent, was the subject of surprised comment and of a representation to the railway companies. The honorary secretary of the federation (Mr. John Hatton, director of the baths at Bath) reported on the position with regard to the treatment of insured persons at the spas arising out of the recent report of the Royal Commission on National Health Insurance. Some important administrative details still remain to be settled, but it is hoped that the time is within measurable distance when insured persons suffering from rheumatic diseases will be able to obtain the benefits of mineral water and other treatments at the British spas. In comparison with France England suffers from the lack of any chairs or lectureships in medical hydrology at the universities or medical schools. During the past two years an effort has been made to meet this to some extent by occasional lectures on the subject at a number of medical schools at the universities and hospitals. This work has been undertaken by a body of medical experts known as the Committee for the Study of Medical Hydrology in Great Britain, and at its last meeting the British Spa Federation decided to continue its financial support of this important work. Grants were voted also to the International Society of Medical Hydrology and to the British Committee on Rheumatism.

DR. HENRY DEVINE, O.B.E., for the past twelve years medical superintendent of the Portsmouth Corporation Mental Hospital, has been appointed medical superintendent of the Holloway Sanatorium, Virginia Water, an institution for the care of insane and nervous invalids of the upper and middle classes. Dr. Devine is M.D. of the Universities of London and Bristol, was elected F.R.C.P. in 1919, and during the war was consulting neurologist to Netley Hospital. His character and attainments have caused him to be held in the highest esteem by his colleagues in the specialty to which he has devoted his life. He is a man of independent judgement and very widely read, and is well known, both to the profession and beyond its borders, for his success as an administrator. He is co-editor of the *Journal of Mental Science*, and is one of the editorial committee of the *Journal of Neurology and Psychopathology*. At the Annual Meeting of the British Medical Association at Portsmouth in 1923 he was president of the Section of Neurology and Psychological Medicine, and has always shown himself ready to place his knowledge and experience at the disposal of the Association.

TUBERCULOSIS.

JOINT MEETING AT CAMBRIDGE.

A JOINT meeting of the Tuberculosis Society and the Society of Superintendents of Tuberculosis Institutions was held at Cambridge on March 25th, 26th, and 27th. The meetings were held in the Pathological Laboratory, by kind permission of Professor H. R. Dean, and arrangements were made for members to stay in St. Catharine's College.

Ultra-violet Rays in Tuberculosis.

The proceedings commenced with a paper by Dr. JAMES CROCKET (Glasgow) on ultra-violet rays in tuberculosis, in which, after a brief account of the history of the treatment, he referred to the variety of available rays. In Scotland there is a paucity of sun rays, and in low-lying districts and in large cities there is a loss of from 50 to 60 per cent. of ultra-violet rays by filtration through fog and soot; the rays are intensified from reflection from snow and sea. He considered the tungsten arc lamp to be the most powerful, and to produce most short-length rays; short-time doses, gradually increased, should be used—five minutes to back and front of the chest up to thirty minutes daily. In his experience cases of tuberculous disease of the glands, bones and joints, larynx, and certain pulmonary cases were benefited by light treatment in addition to other forms of treatment. He found that adenitis of the cervical, mediastinal, and mesenteric glands improved under light treatment combined with x-rays; a year's treatment might be required. Striking results were obtained in tuberculous ulceration of the skin and scrofuloderma, in which general exposure was given; in lupus local application was desirable. In laryngeal infection he obtained help from general exposures combined with light from a carbon arc lamp reflected by a rustless steel mirror on to the interior of the larynx. Tuberculous peritonitis was benefited by combined light and x-ray treatment, and the pain of pleurisy might be removed by three to seven minutes' exposure to the tungsten arc lamp. In pulmonary disease the results were not discouraging. In 72 cases 85 per cent. improved after general exposures; there was a reduction of cough and sputum, sleep was improved, there was no increase in temperature, and no haemoptysis. Light treatment could not cure tuberculosis; it must be used in conjunction with other methods, when it would enable the patient to put up a more effective fight.

A discussion followed, in which Sir STCLAIR THOMSON, Dr. WALTERS, Dr. BASIL PRICE, Dr. JOHNSON, and others took part; emphasis was laid on the necessity for the proper ventilation of artificial light departments, and for the immobilization of cases of surgical tuberculosis undergoing the treatment.

Tuberculosis and Pregnancy.

Dr. GEOFFREY MARSHALL opened a discussion on tuberculosis and pregnancy. At one time, he said, it was held that pregnancy flourished in tuberculous cases, which mostly went successfully to term, and consumptive girls were advised to marry, as pregnancy was considered to benefit the tuberculous. Statistics were difficult to obtain, but available data tended to show that parturition did increase mortality in the tuberculous. Bronchitis not infrequently occurred during pregnancy, and cleared up after delivery. Of 25 tuberculous mothers, 3 were apparently unaffected by pregnancy or confinement, though subsequently they declined; 4 had a definite exacerbation soon after delivery; 19 became worse during pregnancy, and of these 5 had an obvious exacerbation during the third month. Of 118 children of these infected women, 44 died in infancy.

Dr. ERNEST WARD held that 60 per cent. of tuberculous women were unaffected by pregnancy, that the condition of 20 per cent. was improved, and that marriage had a beneficial effect on tuberculosis. On the child the effect was very bad; the offspring of a tuberculous mother were seven times more liable to infection than others. Dr. JANE WALKER was of opinion that any acute pulmonary tuberculosis was definitely made worse by pregnancy. Sir STCLAIR THOMSON asked for guidance as to the truth of two categorical statements which he had accepted for many

years—namely, that a tuberculous woman might have one pregnancy, possibly two, but never a third; and that premature induction did not benefit the mother. Dr. YOUNG said that from a large experience of childbirth in general practice he was convinced that pregnancy and parturition were definitely harmful to the tuberculous.

Catarrho-pyogenic Infections and Phthisis.

Sir HUMPHRY ROLLESTON, Bt., Regius Professor of Physic, in opening a discussion on catarrho-pyogenic infections and tuberculosis of the lung, began by welcoming the visitors, and said that Cambridge was an appropriate centre for such a meeting, for that great man Sir Clifford Allbutt and the late Professor Sims Woodhead were keenly and actively interested in Papworth Colony in the immediate neighbourhood, which was organized with such conspicuous success by Dr. P. C. Varrier-Jones. "Catarrho-pyogenic and tuberculous infections of the lower respiratory tract" was the title of Dr. Batty Shaw's Bolingbroke Lecture, published in the BRITISH MEDICAL JOURNAL of December 26th, 1925 (p. 1212). In that lecture he considered "the possible influences one sort of infection has upon the effects of another different kind of infection," criticized the current conception of pulmonary tuberculosis, and pleaded for a revision of the nomenclature. These difficult problems might well be discussed. The subject of catarrho-pyogenic infection, combined with tuberculosis, active or quiescent, raised a number of questions. When a tuberculous focus, though progressive, was closed and so not made manifest by tubercle bacilli in the sputum, it would not be justifiable to certify the condition as tuberculous. The right policy surely was to "wait and see"; such a course would be in accordance with Dr. Batty Shaw's views. The time relations of tuberculous and other pulmonary infections were of interest and might vary in different cases. Of course, the signs of bronchitis might be recognized before the existence of pulmonary tuberculosis was proved by the demonstration of tubercle bacilli in the sputum; but in such cases it was very difficult to prove the absence of closed tuberculous lesions which, by their presence, had favoured a catarrho-purulent infection. Dr. Batty Shaw had definitely laid it down that tubercle bacilli did not encourage catarrho-pyogenic infections; but this statement might apply only to the tubercle bacilli and not to the presence of tubercles, for it was difficult to deny that the presence of tuberculous material did not, by reducing the local resistance, favour a secondary infection. With regard to ordinary chronic bronchitis and the subsequent incidence of pulmonary tuberculosis, Sir Humphry's own impression was that this sequel was rare, and, indeed, that a moist condition of the lung, such as occurred in chronic bronchitis, militated against tuberculous infection by facilitating the removal of tubercle bacilli before they had time to invade the lung tissue. The influence of the catarrho-pyogenic infection of the lung in favouring pulmonary tuberculosis might occur in one of two ways: (1) By allowing the entrance of tubercle bacilli inhaled from without to take place through a breach of surface into tissue with its power of resistance reduced. The site of the catarrho-pyogenic infection was usually in the lower part of the lungs and not in the apices. This was against the acceptance of this sequence of infections; further, though no great stress could be laid thereon, a local infection might tend to prevent the spread of tuberculous infection into the lung by obliterating the lymphatics. (2) By activating latent obsolete tuberculosis acquired in early life in from 75 to 90 per cent. upwards of urban dwellers; this would be an infection from within, and was suggested by the appearance of symptoms and physical signs of tuberculosis after measles, influenza, and other diseases which reduced general resistance. As tuberculous infection in early life was mainly in the lymphatic glands at the root of the lung, an extension due to a breakdown of the local defences would be expected in this situation; but, probable as such a sequence would appear, tuberculosis starting primarily in the lower lobes of the lungs was unusual in adults, though, of course, radiological examination might reveal areas of infiltration unsuspected clinically; the mechanism of infection from within still needed further elucidation. That bronchitis often super-

vened on existing tuberculous disease of the lungs did not require any argument; but how often bronchitis, by, so to speak, washing out the bacilli, revealed a carrier of tubercle bacilli which were not doing any damage by their presence was another question; no doubt such cases cropped up from time to time, but it was a dangerous assumption, in the light of the extreme chronicity of tuberculous lesions of the lung, to assume the existence of tuberculous carriers on the same lines as pneumococcus carriers. Sir Humphry Rolleston concluded by discussing the question of nomenclature raised by Dr. Batty Shaw. Mixed infections in pulmonary tuberculosis were so common and were often serious from the prognostic standpoint, that, though it might be etymologically correct, it would appear undesirable to alter the nomenclature in any way that would lose sight of the primary underlying factor, or to confine the term "pulmonary tuberculosis" to a pure infection with the tubercle bacillus.

Dr. BATTY SHAW referred to the age incidence and mortality among tuberculous children, pointing out that from 1 to 3 years the infection was largely military; from 5 to 10 years there was an ascending curve of pulmonary infection. Radiography had convinced him that the terminal stages of pulmonary tuberculosis were due to something in addition to the tubercle bacillus. Dr. Clive Riviere had suggested that the victim frequently reinfected himself. Hilus tuberculosis had come to stay; it might not give rise to physical signs, but the diagnosis was confirmed by x rays and examination of the sputum. Dr. Shaw gave figures of *post-mortem* examinations by Gohn showing that infection occurred in approximately 53 per cent. of cases in the upper lobe and 47 per cent. in other parts of the lungs. He concluded that the disease spread from the hilum owing to the supervention of infection by catarrho-pyogenic organisms. Pus and blood in the sputum did not come from pure tuberculous infections but from a superimposed infection by pyogenic organisms.

Dr. ERNEST WARD found Dr. Batty Shaw's remarks very stimulating; some were very true, some were very false. Probably some 40 per cent. of all people were at some time or other infected with tuberculosis; some had a high resistance, others a low resistance, and these were the subjects of the military variety; the middle grade suffered from fibro-caseous tuberculosis and cavitation. A case of catarrhal pulmonitis might become infected by tuberculosis from without or within. Carriers, especially grandmothers, were a very real consideration. Dr. Ward did not agree that the tubercle bacillus did not cause the formation of pus.

Dr. F. R. WALTERS remarked that the presence of tubercle bacilli in the body did not cause illness; this was due to failure of resistance. Granted a primary infection, the disease was chiefly due to non-tuberculous causes.

Dr. VERE PEARSON held that the physical signs and symptoms of pulmonary tuberculosis were distinct from those of catarrhal affections, and that it was usually possible to say in any case of relapse whether the condition was due to tuberculosis or to catarrhal organisms. During the past twenty-nine years he had administered vaccines for secondary organisms in a large number of cases of pulmonary tuberculosis. In only a very small proportion had he been able to ascribe undoubted benefit to the treatment. In his opinion hilus tuberculosis was a very rare condition.

Dr. CROCKER said that if in the examination of sputum many other organisms were present, it was unlikely that tubercle bacilli would be found. He referred to a case of apparently advanced disease with high temperatures and much sputum, which very much improved under treatment by vaccines of streptococci and staphylococci. He believed relapses were often due to lack of rest, and that hilus tuberculosis was of very frequent occurrence—a pre-pulmonary condition. A great deal of chronic bronchitis in elderly people was associated with tuberculosis; such people were dangerous to the community.

Galvano-cautery Treatment of Laryngeal Tuberculosis.

Sir STCLAIR THOMSON spoke of the indications, technique, and results of galvano-cautery treatment of tuberculosis of the larynx. As a local help the galvano-cautery was a most useful adjunct, but the cases in which it should be

used were relatively few. Of such cases a large proportion were cured. The most favourable sites were the margins of the glottis; it should not be used where the glottis was infiltrated. If in spite of sanatorium treatment the condition, generally, was not improving, the cautery should not be used. Disease in the chest might be improving while the condition in the larynx was stationary; but the converse was rarely seen. At Midhurst, in 620 cases only 103 were considered suitable for treatment by the galvano-cautery; of these 64 per cent. were cured. The technique was described.

Dr. TRAILL emphasized the value of an expert opinion on the larynx and considered the galvano-cautery a great adjunct in the hands of an expert. In quiescent cases there was no reaction of any consequence after treatment.

Sanocrysin.

Professor LYLE CUMMINS gave the results of his experience with sanocrysin. He considered it to be an actively beneficial drug in the treatment of pulmonary tuberculosis, but a potentially dangerous remedy. It certainly had some bactericidal action on the tubercle bacillus in the tissues; it freed toxic substances and was a metallic poison. Those cases in which there was a prospect of relief could now be recognized. Careful consideration must be given to the nature of the lesion and the density of the infiltration; also to the state of efficiency of the eliminative organs, such as the kidneys. The advanced toxic case was unsuitable; the early case in good general condition was likely to do well. The use of 2 rays, co-ordinated with clinical signs, was absolutely indispensable. With regard to dosage, at first undoubtedly too large doses at too short intervals were given. The drug was cumulative, and gold might take as long as a month to be excreted. For a resistant, afebrile case he recommended commencing with a dose of 0.25 gram, and increasing by this amount at seven days' interval to 1-gram doses. A total of 6 grams should be given. In pyrexial cases in an early stage 0.2 to 0.75 gram should be given and repeated at seven-day intervals; no further dose should be given until all visible effects had subsided, and a tolerance developed. In spite of some reaction it was found that cough, sputum, and fever all diminished, and tubercle bacilli disappeared from the sputum; weight usually increased after the course was finished. Danger signals were a diminution in the amount of urine, the occurrence of aphthous ulcers in the mouth, diarrhoea, and a tendency to sweating, indicating a postponement of the next dose. Complications were rise of temperature, albuminuria, loss of appetite, jaundice, general exfoliative dermatitis, shock, and an oedematous condition of the lungs. The first four cases were a dramatic success, but they all relapsed; however, after a subsequent course of injections they all recovered. The paper was illustrated by a striking series of lantern slides. Dr. HEATH related his experience of twenty-eight cases treated with large doses. On the whole the results were favourable. Two cases became definitely worse with profuse sweating and the presence of pus and tubercle bacilli in the urine.

Artificial Pneumothorax.

Dr. H. DE CARLE WOODCOCK opened a discussion on artificial pneumothorax, with a demonstration of apparatus. He was in favour of a double manometer which would indicate when the gas was flowing. Dr. PARRY MORGAN demonstrated such an apparatus.

Mr. MORRISTON DAVIES considered that though this form of treatment was a great asset in many cases others were unsuitable and did not do well. Phrenic evulsion helped in some, especially those in which there were adhesions about the lower lobe between diaphragm and lung, and thoracoplasty was indicated in certain conditions such as thin-walled cavitation. His remarks were amply illustrated by an excellent series of slides. Dr. VERE PEARSON described the condition of mediastinal bulging after artificial pneumothorax had been induced. Displacement of the heart and bulging of the posterior mediastinum were observed and were due to too high pressures.

Dr. JANE WALKER gave the end-results of 132 cases treated by induction of artificial pneumothorax during the

period 1912-23. Of these, 21 were under 16 years of age; in 13 tubercle bacilli were present in the sputum; 12 had died, and 9 survived. Of the total number there were numerous tubercle bacilli in the sputum of 114, and none in 18. The total mortality was 65.76 per cent.

Dr. BURRELL reported 309 cases treated by artificial pneumothorax; of these, 128 developed a considerable quantity of fluid and 181 did not. The mortality among those with fluid was 41.4, and among the others 36.7 per cent. In cases with clear fluid the mortality was 29.3 per cent.; in those with pus it was 55 per cent. He concluded that the effusion of clear fluid did not influence the mortality. The effusion did not depend on the gas used or on its warmth; it was a tuberculous process. In spontaneous pneumothorax 18 out of 23 developed pus; the outlook was serious and thoracoplasty should be considered.

Dr. Z. P. FERNANDEZ said that pleural effusion had been a rare occurrence in Leeds during pneumothorax treatment. He thought that replacement of the fluid was less beneficial than simple aspiration.

France.

(FROM OUR SPECIAL CORRESPONDENT.)

Foreigners in Paris Hospitals.

FATE seems to have decreed that those countries most sorely tried by the war and with a depreciated currency should afford an irresistible attraction to foreigners. Some of these foreigners help the country to live, but others are parasites difficult to put up with. Recent statements—notably those of M. Weil to the Académie de Médecine, and M. Marie to the Medical Society of Paris, dealing with the proportion of foreigners in the hospitals of Paris—have attracted the attention, not only of the public authorities, but also of the public at large. M. Berthoumeau has now raised this same question in relation to the great convalescent home for patients discharged from the hospitals of the capital. He finds that 14.6 per cent. of the inmates were born outside French territory; in 1914 the percentage was 5.6, and even that was a heavy charge on the ratepayers. There seems to be no remedy short of establishing rigorous medical inspection at the frontier. It is to be noted that the number of British subjects in Paris hospitals is negligible.

Treatment of Pulmonary Tuberculosis with Sanocrysin.

Once again we have evidence that every new subject is discussed more or less simultaneously in Paris and in London; thus, while the Section of Medicine of the Royal Society of Medicine was engaged in discussing sanocrysin, the same subject was being debated by the Section for Scientific Study of the "Œuvre de la Tuberculose," of which our best known specialists are members. Their conclusions are not so encouraging as those of our British confreres. Professor Bezançon, who has treated twenty-six cases, obtained favourable results in two only. In his opinion sanocrysin has no effect on the fever, the pulse, the cough, or the expectoration. It does not produce any modification in the skin reaction, nor on the deviation of the complement by the tuberculous antigen. Professor Bernard does not regard sanocrysin treatment as specific. The symptoms produced in the patient are not, he thinks, related to an intoxication due to the liberation of tuberculous poisons and toxins, but to the metallic nature of the remedy, and Dr. Rist finds his results far from being as positive as those announced by the Danish authors. Professor Sergent reports disastrous results in two cases and favourable results in four; no effect was observed in eight other patients. M. Calmette has reported some laboratory experiments from which he concludes that *in vitro* the gold salt is little toxic for the tubercle bacillus. Experiments on rabbits did not give evidence of any modification of the virulence of the tubercle bacilli. Sanocrysin does not liberate any specific toxic principle. Finally, the antituberculous serum, the use of which is proposed in order to limit the toxic effects of sanocrysin in tuberculous subjects, does not modify the toxicity of tuberculin. In conclusion, it may be said that the French

observations and experiments support the attitude of Sir Almroth Wright in opposing the views expressed by clinicians who took part in the discussion at the Royal Society of Medicine.

Prevention of Syphilis by Bismuth.

MM. Fournier and Schwartz have reported to the Académie des Sciences the result of their researches on the preventive action of bismuth in experimental syphilis in the rabbit. They have shown that intramuscular injections of bismuth protect the animal effectively against syphilitic infection; the refractory state lasts from three to six months; the duration is proportional to the dose administered, but is influenced also by whether the salt used is insoluble or soluble, being longer in the former case. Guided by these results, the authors have begun to test the value of bismuth in the prevention of syphilis in human subjects specially exposed to possible contamination.

Social Service in Hospitals.

The fourth year of the system of social service, copied from the organization which exists in the United States, has just come to an end. In 1922 the number of such services in Paris was thirteen; now it is forty, seven of which have come into existence during the last year. It is not a charitable undertaking, but a simple and practical method of helping to meet the expenditure of the hospitals, whose existence is made necessary by agglomerations of population. Previously the organization was chiefly concerned with tuberculosis, but during the past year it has attacked a much more delicate problem—that of syphilis. It is easy to understand that difficulties of all kinds are encountered by the women visitors who have to inquire into the family situation of such patients. But the results are most encouraging. It seems that everything depends on the tact and devotion of the lay missionaries who undertake this ungrateful task. Immense progress has been achieved since the war, and is changing altogether the attitude of the hospital, which has ceased to be content to act merely as a place of refuge, but is coming out of its entrenchments to assault the enemy positions. Not only does the community profit, but the teaching of students is becoming more humane and more genuine. This is one of the most striking results of the evolution of modern conceptions and a great advance on the road on which the French have been long preceded by the English-speaking nations.

Social Assurance.

The assurance law on which I have written on several previous occasions will shortly be discussed by the Senate, which it can hardly be doubted will pass it, as has the Chamber of Deputies. The great majority of the French medical profession do not believe that this law will assure to the beneficiaries the best medical treatment; they believe, however, that the measure will be improved in the course of time, and therefore consider it unwise to fight any more against the inevitable. Behind this law are hidden political manoeuvres, the nature of which it is not difficult to guess. It is very much to be regretted that we have not in France an organization comparable to the British Medical Association, which possesses the authority necessary to speak in the name of all medical practitioners. The organization which approaches it most nearly is the Union of Medical Syndicates. Unfortunately, at the time when the Union is most necessary to us, a schism has broken out in it concerning some questions of procedure regarding this new bill which we are expecting to become law. It is still possible to hope that the Union will surmount its differences; if not they will bring about our ruin, for we shall see ourselves lose advantages which it has taken long to win, discredit will fall on our corporate mentality, and feelings of doubt and hesitation will take possession of our minds; it will be a lamentable defeat for our liberal profession, which owes it to itself, particularly in times so difficult as those in which we live, to maintain an attitude of dignity and serenity. We envy Great Britain its professional organizations. We can only console ourselves with the hope that our present griefs will help to provide us with sure foundations for the establishment of a French Medical Association on the model of the British.

Scotland.

EDINBURGH MEDICAL FACULTY BICENTENARY.

IN connexion with the bicentenary of the Faculty of Medicine at the University of Edinburgh, which is to be celebrated in June of the present year, the Senatus Academicus has resolved to offer the honorary degree of LL.D. to the following: Andrew Balfour, C.B., C.M.G., M.D., Director of the London School of Hygiene and Tropical Medicine; Robert Howden, M.B., C.M., Professor of Anatomy, Durham; Sir George Newman, K.C.B., M.D., Chief Medical Officer, Ministry of Health and Board of Education; Alexander Primrose, C.B., M.B., C.M., Professor of Clinical Surgery, University of Toronto; Sir John Robertson, C.M.G., O.B.E., Professor of Public Health, University of Birmingham; Ralph Stockman, M.D., Professor of Materia Medica, University of Glasgow; Arthur Logan Turner, M.D., President of the Royal College of Surgeons, Edinburgh; Sir Norman Walker, M.D., LL.D.; James Thomas Wilson, M.B., C.M., F.R.S., Professor of Anatomy, University of Cambridge.

GLASGOW ROYAL INFIRMARY CLUB.

The annual business meeting, followed by the annual dinner, of this club was held in St. Enoch's Station Hotel, Glasgow, on the evening of March 12th, when the president, Sir John Thomson-Walker of London, occupied the chair. There was a large attendance of members, the company numbering ninety-three. After the toast of "The King" had been pledged, the chairman proposed the toast of the "Glasgow Royal Infirmary" in a speech which was largely reminiscent of his own time as resident in the old Royal Infirmary. Replies were made by the guests of the evening—Professor A. Louise McIlroy, London, and Dr. A. Maitland Ramsay, honorary director of the James Mackenzie Institute for Clinical Research, St. Andrews. The toast of "Past and Present Residents" was given by Professor J. M. Munro Kerr, and was responded to by Professor John R. Currie on behalf of the past residents, and by Dr. McCrone for the present resident staff. The toast of "The Chairman" was proposed by Professor Archibald Young, and Sir John Thomson-Walker suitably replied. The joy of the evening was enhanced by songs from Dr. A. N. McLellan, Dr. A. Charteris, Dr. G. Dalziel, and Dr. J. Henderson. During the evening, as on former occasions, a collection was taken on behalf of the Royal Medical Benevolent Fund Guild, and a sum of over £8 was realized. Dr. R. O. Adamson, Glasgow, was appointed chairman for next year.

CLOSE OF THE WINTER SESSION IN THE GLASGOW EXTRAMURAL SCHOOLS.

In the Anderson College Dr. A. Maitland Ramsay, of the James Mackenzie Institute for Clinical Research, St. Andrews, delivered an address to the students on medicine as a career, in which he made special reference to preventive medicine as the greatest achievement of all medical work in ridding the community of many ills. As instances he gave the conquest of malaria and of typhus fever. Their constant endeavour should be to discover the cause of disease, and thereby to arrive at preventive methods. He advised the students to cultivate the spirit of research, even in ordinary practice, as much could be done in that way even apart from laboratories; it would also give to practice an added interest. At the closing meeting of St. Mungo's College, the chairman, Dr. James Macfarlane, D.L., addressed the students, and his remarks were supplemented by those of Dr. James MacKenzie. In both colleges, medals, prizes, and certificates were presented to the successful students.

"PROPOSED NEW CHILDREN'S HOSPITAL AT ABERDEEN.

At the annual meeting of the Aberdeen Royal Hospital for Sick Children it was intimated that an appeal to the public which was made last year for £45,000 had been met to the extent of £34,035 by subscriptions. The first appeal for funds for a new hospital had been made in 1910, and the directors had only recently seen their way

to proceeding with plans for the erection of a new building. It was estimated that the cost of the new hospital would be £100,000. A site had been provided by the generosity of Mr. and Mrs. Herbert Taylor (Aboyne), and the directors would shortly make arrangements for laying the foundation stone of the hospital. H.M. the Queen was re-elected patroness of the hospital, and the Marchioness of Aberdeen and Dowager Lady Burnett of Leys were elected vice-patronesses.

TESTIMONIAL TO DUNDEE RADIOLOGIST.

The committee in charge of the public testimonial to Dr. George A. Pirie in recognition of his pioneer work as a radiologist and of the disablement he had received by assiduous attention to this work, at a meeting on March 23rd, agreed that the presentation should take the form of a cheque for 1,000 guineas.

Ireland.

MEDICAL ORGANIZATION IN NORTHERN IRELAND.

At a meeting of medical men in County Tyrone, held recently, it was decided to form a branch of the British Medical Association for the county, and a resolution was passed unanimously that the Belfast Medico-Political Committee did not represent the medical profession throughout the Six Counties, and had no right to make representations to the Northern Government on behalf of any medical men except those resident in the immediate neighbourhood of Belfast. Further resolutions were passed in favour of the appointments of school medical officers being left in abeyance pending the appointment of a medical officer of health for the county, and stating that medical certificates should not be issued free in the case of school children who are ill, but the Regional Committee should pay a reasonable fee for certificates for children who are dispensary patients.

The following reply has been published by the Medical Committee of Northern Ireland:

We note that at a meeting of the medical practitioners of County Tyrone a resolution was passed to the effect that the Belfast Medico-Political Committee does not represent the medical profession throughout the Six Counties and has no right to make representations to the Government on behalf of any medical men except those resident in or in the immediate neighbourhood of Belfast. We should like to let the public know that: (1) There is no such body in existence as the Belfast Medico-Political Committee. (2) There is a Medical Committee of Northern Ireland. (3) This Committee is constituted as follows: (a) The Council of the Ulster Branch of the British Medical Association; (b) the Council of the Ulster Medical Society (these are the only organized bodies of the medical profession in Northern Ireland); (c) a representative of the Medical Faculty of the Queen's University of Belfast; (d) two representatives of each of the local Medical Committees of the County Borough of Belfast and Londonderry, and of each of the Six Counties of Northern Ireland. If a Medical Committee so constituted has no right to speak on behalf of the profession in Northern Ireland, it is difficult to see what should be the constitution of a committee that would have such a right.

(Signed)

R. J. JOHNSTONE,

Chairman.

H. P. MALCOLM,

ROBERT MARSHALL,

Honorary Secretaries, Medical Committee
of Northern Ireland.

THE CORONERS BILL (IRISH FREE STATE).

A Select Committee of the Senate has had under consideration the Coroners Bill, 1925. Lord Glenavy, who presided, said that the bill in its present form was a very meagre measure and dealt only with what were the present duties of the coroner. The only recommendation for the first section was that it was taken 'practically from the bill that was now before the House of Lords. He suggested that it would be better for the Committee to discuss the whole question with regard to coroners' duties. Senator Brown, K.C., then explained that there were three Acts governing the duties of coroners in Ireland. The first was the Act of 1846, the second the Act of 1881, and the third the Local Government Act of 1898, transferring the appointment of coroners to the county councils. The law left it in the discretion of a coroner to hold an inquest,

except in cases where there was reasonable cause for suspicion that the person died by violence or unnaturally, or through some cause unknown, or died in prison. He suggested that the coroner should be empowered to hold a *post-mortem* examination, and if the report satisfied him as to the cause of death no inquest should be necessary. Senator Brown also explained the provisions of the bill at present before the House of Lords, and suggested that sections should be embodied in the present measure dealing with the powers of a coroner to hold inquests without summoning a jury, also limiting the jury summoned to twelve in number, and obviating the necessity, as at present, for the jury to view the body. Sir E. Coey Bigger said that at present there was no way to certify the cause of death in 70 per cent. of the deaths in country districts. A provision should be inserted in this bill directing that the coroner should hold an inquest in every case where no certificate of medical attendance at death was sent to the registrar. This would help in the compilation of statistics, which at present afforded no information on the point. After further discussion Senator Brown promised to prepare and circulate his suggested amendments, which would be considered by the Committee at its next meeting.

QUEEN'S UNIVERSITY OF BELFAST.

After the spring ceremony for the conferring of medical degrees in the Queen's University, Belfast, on March 26th, a tablet to the memory of the late Right Hon. J. C. White was unveiled by Mrs. White in the new biochemistry and bacteriological laboratories. The Vice-Chancellor presided, and explained that owing to the munificent gift of £60,000 by the late Mr. White the University was now in a position to have a professor, a lecturer, and an assistant in biochemistry, and a lecturer in bacteriology. These departments were well equipped, and, by the grants provided, the authorities would be enabled to keep them thoroughly up to date. This munificent bequest meant the endowment of the study of two important branches of medicine, both of which originated in the work of Pasteur; the discovery of insulin and of vitamins was proof of the value of chemistry. To make full use of their hospitals universities would have to carry on research and to train the doctor for hospital duties. The pathologist and the chemist might make a discovery which would revolutionize methods and means. The war against disease was waged on a wide front, and the final discovery was the result of endless research all over the world. The medical faculty had 400 students, and this gift would enable them to be well taught, so that they went forth properly trained and equipped. Mrs. White then unveiled the tablet, which bears the following inscription:

"In memory of the Right Hon. John Campbell White, Privy Councillor, some time Lord Mayor of Belfast, under whose testament the studies of biochemistry, for which this building is designed, and of bacteriology, were endowed, and the professorship and lectureships that bear his name, founded in this University, 1924."

A vote of thanks to Mrs. White was proposed by the Lord Mayor and seconded by Professor Lindsay, who said that Belfast was following the very laudable and wise example of the United States of America in the liberal endowment of research.

England and Wales.

LIVERPOOL MEDICAL INSTITUTION: JUBILEE OF DR. THOMAS CLARKE.

A SPECIAL meeting of the Liverpool Medical Institution was held on March 23rd to congratulate Dr. Thomas Clarke on reaching his jubilee year of membership of the Institution. Sir James Barr, proposing the resolution of congratulation, reviewed the salient points of Dr. Clarke's professional career. He went to Liverpool in 1872, and after having held a post of ship surgeon was a resident medical officer for three years in the Brownlow Hill Infirmary, after which he commenced the private practice in which he was still actively engaged. In 1879 he was appointed honorary physician to the Hospital for Consumption and Diseases of the Chest, which post he held till 1911,

when he became consulting physician. During the war he resumed active work till 1919, owing to the depletion of the staff. He also held the appointment of visiting physician to the East Dispensary. He joined the Liverpool Medical Institution in December, 1875, and was vice-president in 1923-24. Dr. Thomas Clarke had taken an active part in civic affairs, and proved himself an indefatigable worker, gifted with sound judgement. In 1893 he became a city councillor, and served for several years on committees. In 1895 he became chairman of the Port Sanitary and Hospitals Committee, and in 1901 was made an alderman. On his retiring from the chairmanship he had the unique distinction of being presented with a handsome testimonial. In 1897 he was appointed a magistrate of the city, and still exercised his magisterial duties. Since 1889 Dr. Clarke had held the post of medical referee under the Workmen's Compensation Act. Dr. William McAfee (West Kirby, Cheshire), seconding the resolution, said that his friendship with Dr. Clarke dated from 1876, when he became a fellow resident with him at the Brownlow Hill Infirmary. At that time the nursing of the patients was of the most elementary type, but this was later remedied through the influence of the late Mr. William Rathbone. Dr. Clarke had rectified numerous difficulties in the infirmary, and his success there foreshadowed that ability which he had so successfully displayed in municipal affairs. Dr. E. W. Hope, late medical officer of health, supporting the resolution, said that it was owing to Dr. Clarke's tact and perseverance that the city had been able to secure the Fazakerley estate for the erection of the fine hospital there. Dr. Clarke had been indefatigable in visiting various hospitals in the country so as to ensure that the structural arrangements should be complete in every particular. Dr. Hope mentioned how much Dr. Clarke had endeared himself to the members of the committee, and how they deplored his resignation from the post of chairman. Dr. J. C. M. Given, president of the Liverpool Medical Institution, then put the resolution to the meeting, emphasizing the great public service Dr. Clarke had rendered; it was carried with acclamation. Dr. Clarke, replying, said that he greatly appreciated the honour the Institution had paid him. He gave numerous reminiscences of his experiences as a ship surgeon and as a resident medical officer at the Brownlow Hill Infirmary on the medical as well as on the surgical side. When he began private practice, at the end of two months' work he made £1, but at the end of six months he was self-supporting. He admitted that municipal affairs had engrossed his attention when not occupied with the exigencies of practice. His domestic life had been happy; a widower now, he was the father of eleven children, and in May next he would complete his 80th year. He attributed his good health to plenty of occupation and the friendly sympathy of those with whom he came into contact. Lastly, he enjoyed a good dinner, which was incomplete without a good glass of wine. He regularly took a warm bath in the morning followed by a cold shower, which he regarded in the light of a tonic for the day's work. In conclusion Dr. Clarke expressed his sincere thanks for the honour the Institution had paid him.

NATIONAL LEAGUE FOR HEALTH, MATERNITY AND CHILD WELFARE.

The wide range of activities of the National League for Health, Maternity and Child Welfare and of its constituent sections is illustrated by the annual report for the year ending December 31st, 1925. The League came into existence in 1905, largely in consequence of the issue in the previous year of the report of the Royal Commission on Physical Deterioration. Since then it has played a pioneer part in promoting the establishment of infant welfare centres, and in providing education in mothercraft, the laws of health, and kindred subjects. During the year under review a cinematograph film was prepared to show how all classes in elementary schools in Sheffield carried on a simplified physical training in confined playgrounds, and how the children were taught organized games and swimming. It is stated that the film is available, free of charge, for any local education authority or individual school for demonstration to teachers, parents, or the general public. Health lectures have been given to working

girls' clubs, girl guides' companies, branches of the Mothers' Union, and to factory workers. The League was responsible for a very large number of new publications during 1925. These included pamphlets and small books dealing with everyday psychology in the nursery, cookery for children, maternity and child welfare centres in rural districts, and the work of ante-natal centres. Several of the publications of the League have now been translated into foreign languages. The sales reached nearly 450,000 copies, as compared with 397,000 copies in 1924. The League's report includes the annual reports of the associated societies and a statement of accounts for 1925.

Correspondence.

EFFECT OF INTRAVENOUS INJECTIONS OF GLUCOSE ON THE ACTION OF X RAYS.

[Translation.]

SIR,—Working in my institute in the General Hospital, Vienna, and in Professor Hajek's laryngological clinic, Dr. E. G. Mayer has discovered that the effect of irradiation of non-malignant and malignant tumours is much increased if it is preceded and followed by the intravenous injection of glucose. The solution employed contains 30 per cent. of glucose, and is administered in doses of 10 c.cm. The glucose must be quite pure and free from albumin. The injection is made shortly before each irradiation, and subsequent injections are not required. No modification in the administration of the x rays is needed.

Dr. Mayer brought the subject before the Medical Society of Vienna and showed several remarkable cases and reported on twenty others, in more than one-half of which an enhanced effect was recognizable. During the subsequent discussion Professor Hajek expressed the opinion that the results were superior to any hitherto observed. In order to obtain a true estimate of the value of Mayer's method it is necessary to compare the results with those obtained with x rays alone. It has been ascertained that, in sarcomata treated by the latter method, a primary atrophy of the tumour occurs in about 30 per cent., with prolongation of life. The diminution of the growth commences in a few days and extends over some weeks; there is, therefore, a short latent period and a rapid course. In carcinoma the action is less satisfactory and much more prolonged. In about 2 per cent. of the cases cure lasting for five years has been observed. In the relatively favourable carcinoma of the cervix uteri the percentage reaches 10 to 20; with growths in many other regions the result is often nil. The primary diminution of the tumour in favourable cases begins about the third to the sixth week, and the action continues in varying degrees for some months. The latent period in the case of carcinoma is, therefore, long, and the course has to be prolonged. In cases treated by Mayer's method, some of which I have myself observed, there is, in the first place, a deviation from these results, both as regards the latent period and the rapidity of the subsequent atrophy. The first evidences of a diminution in the size of the growth appear much earlier; the latent period, reckoned by weeks with the older method, would be reckoned by days with Mayer's method. The subsequent atrophy is, moreover, more rapid in its course. In the second place, cases which are considered to be unfavourable for treatment with x rays alone, or in which their administration has been found to be without effect, are brought under the influence of irradiation when treated by Mayer's method. It may be said that, as the result of the injections of glucose, carcinoma acquires the characters of sarcoma in respect of its reaction to the x rays. Combined treatment in x-ray work has hitherto consisted of the employment of some agent (1) conjointly with the x rays, to produce an added effect; (2) before applying the x rays, to produce a sensitizing effect; (3) after the x rays, to produce an adjuvant effect. In the first case may be mentioned Bier's injection of tumours with the patient's serum and the numerous tumour serums; the application of scarlet-red to ulcerating growths and pre-cancerous lesions, in which an undoubted effect has been

observed; Andersen's treatment of carcinomatous ulcers with sodium chloride in high concentration, the action of which extends to a considerable depth and sometimes leads to healing, as I have myself observed; and the tumour autolysates of Juvanovic and the recent tumour serum of Blumenthal, which are employed both in superficial and deeply seated carcinoma. To obtain sensitizing and adjuvant effects the parenteral administration of sodium chloride and albumin and the so-called fever therapy have been tried, but notwithstanding favourable reports I do not anticipate that much advantage is to be expected from these measures.

With Mayer's method permanent results are, naturally, not to be looked for; there is no question of cure. On the other hand, it promises to be more effective than the x rays have hitherto been, and has already been of great service in the more distressing type of cases. The fundamental position of surgery in the treatment of tumours remains unaltered; Mayer's treatment merely confers on irradiation a rapidity of action hitherto unknown, and brings under its influence types of tumour which so far have proved to be refractory to x rays alone.—I am, etc.,

G. HOLZKECHT,
Professor, Roentgen Laboratory, Allgemeine
Krankenhaus, Vienna.

MENTAL IRRITABILITY AND BREAKDOWN IN THE TROPICS.

SIR,—I am inclined to think that the nervous irritability mentioned by a correspondent in your issue of March 13th (p. 503) is due to the brightness of the sun's rays.

This irritability is not confined to the tropics. I practised for three years in Alberta, Canada. Friends remarked to me on arrival that nervous breakdowns were very common, and that everyone had to go "to the coast" after two years' stay. During my first winter I was particularly energetic and invigorated, not feeling the cold to any extent. During the last winter I became more irritable, more sensitive to cold; "one's blood got thinner," in local parlance. Now the climate, as everyone knows, in the winter is very dry, very bright, and very cold, with snow to accentuate the rays of the sun. It was a very pronounced physical relief to put the light out at night. In the summers which were stormy, damp, and hot one did not feel this irritation nearly so much.

I found too, in giving anaesthetics, that the absorption of both chloroform and ether was extremely rapid, and that with the former the risk of an overdose was great unless great care was taken. The same rapid absorption applied to the taking of alcohol, and men were known to get hopelessly intoxicated on very little if coming fresh into town from the country in the very cold weather. I think that these incidents had some bearing on the demand for prohibition of spirituous liquor.

There is no doubt that nervous breakdowns and other allied symptoms of nervous irritation were common, and the facts seemed to point to the excessive and continuous brightness of the winter season. I compared it to the effect of drinking a couple of glasses of champagne daily year in and year out, the cumulative stimulation of the nervous system resulting in the various forms of breakdown.—I am, etc.,

Long Sutton, Wisbech, March 16th.

R. MURRAY BARROW.

SIR,—The Bishop of Singapore is only too right when, in his letter under this heading in the *JOURNAL* of March 13th (p. 503), he emphasizes the importance of the upset of mental and nervous balance which is so common in the tropics.

A few years ago Sir Havelock Charles wrote a paper on neurasthenia, in which it was pointed out that this disease accounted for far the largest number of the invalidings from India. The same thing is true for West Africa. The sanitarian is steadily getting the better of the parasitic diseases and, in that respect, the tropics become healthier and healthier; but only very little progress is being made in reducing the incidence of neurasthenic troubles, and that small improvement is due to better living and social conditions.

At the Annual Meeting of the British Medical Association at Portsmouth in 1923 Dr. George Mahomed of Bournemouth communicated to the Section of Medicine the results of some investigations he had been making on the electrical content of the atmosphere. He had devised an instrument which measured this, and had been able to show that there was a marked and measurable difference between the electrical content of fresh and vitiated air. He found that this difference was even greater than the chemical difference, and suggested that it was more potent in producing the phenomena due to exposure to a vitiated atmosphere than the usually blamed chemical one. I have seen no note of further similar work.

Now, is it not possible that the nervous deterioration which occurs in the tropics may be accounted for on these lines if the results in the paper referred to have been confirmed? It may be that the electrical content or potential of the atmosphere in the tropics is less than it is in the temperate zones. The nervous mechanism of the inhabitant of the latter is attuned to work in the higher potential and, when transferred to an atmosphere with a lower potential, a continual leak from the analogue of his batteries occurs, resulting in the familiar nervous phenomena and ultimately necessitating the long leave at home for recharging.

I apologize for producing an idea which is so entirely conjectural and for which I can offer no scientific evidence; but it seems no worse, in that respect, than the altitude, the sameness of the climate all the year round, the bright light, and the other theories put forward, and it has the advantage of fitting in with observed facts better than they do.

One can see an analogy between the working of the human organism and a motor car. If the car has a long day of short runs with continual starts from the self-starter and much use of the horn, and a long night with the lights on, the result is that its batteries are run down; if it then gets a long fast non-stop run during which no call is made on its batteries it returns with them fully recharged and fit for more gruelling work. Similarly, if a man does a hard day of worrying work and has a late night he retires worn out, with his batteries run down, so to speak. If he then has a good long rest and sleep he is in much the same position as the car on the long run—his engine is running, but there is no call on his nervous mechanism or "batteries," and he wakes up fresh, fully charged, and fit for work. If, however, he continuously gives himself inadequate rest and sleep the result is a nervous breakdown, for which the cure is a very long and complete rest, just as, in the car, if it never gets a long run, the batteries get completely discharged and have to be sent to the garage for recharging, an annoyingly slow and lengthy process. The car with discharged batteries will run, but no more than run—no self-starter, no horn, and no lights; similarly the man with run-down batteries will exist, but shorn of all his better attributes.

I am obviously no electrician, and see no hope of ever becoming one, or possessing the requisite apparatus to see if there is anything in this tentatively suggested theory; but possibly someone better equipped might look into it. —I am, etc.,

LEAD IN THE TREATMENT OF MALIGNANT DISEASE.

SIR,—If Dr. Adami is satisfied that the suggestion he now puts forward (BRITISH MEDICAL JOURNAL, March 27th, p. 594) explains the apparent discrepancy between his figures and those given by Dr. Blair Bell three pages earlier in the same paper (Lancet, March 13th, 1926), then we may accept it. His suggestion is that the excellent results for which he vouched may have included a certain number of cases which, even three and a half months later, were considered too recent to be classified as "believed cured," a certain number where the cancer had only been arrested, and a certain number which had had incomplete treatment.

¹ BRITISH MEDICAL JOURNAL, 1923, vol. ii, p. 1144.

The acceptance of this suggestion would necessitate two things. First, his description of the cases as "*old patients who had from the beginning been subjected to Professor Blair Bell's treatment*" will have to be withdrawn. Secondly, his statement that "there was not a single example of recurrence in this group" will require to be amended by the addition of some such phrase as "Some of the cases I examined might still bear their original cancer." Such emendations would, of course, considerably change the atmosphere of his report. There may even be other explanations possible, but conjecture could quite easily be converted into certainty if Dr. Adami cared to publish the notes of his examination and compare them with the official records. He will realize that every scrap of evidence justifying the treatment is of importance, and I would earnestly implore him to publish these notes.

It has grieved me very much to think that Dr. Adami should entertain the suspicion that I reflected on his honesty. I, and I am sure all other pathologists, regard him with respect and affection.

Whether it was worth my while dilating on the serious divergencies shown in Dr. Bell's successive reports of his cases, and using these in the forensic method for testing the "credibility of the witness," may be doubtful. The matter is relatively unimportant. Of what I did say at the meeting I retract nothing, I regret nothing. What is of paramount interest is the question of the secrecy of the drug employed. While Dr. Bell vehemently protests that his method of preparation of colloidal lead was disclosed in 1924, and that those who doubt this (of whom I am one) betray colossal ignorance of elementary physical chemistry, he has nevertheless departed from the traditions of medical practice by patenting his preparation. One need not be an authority on physical chemistry to be sure that a patent is never sought for a method already known. On this question my "*animus*," as Dr. Adami calls it, is not concealed. I trust that I shall always be prepared to attack with the utmost vigour I am allowed, and with whatever weapons are at my command, anyone who would dare to withhold from even the humblest member of our profession a professedly successful means of treating inoperable cancer.—I am, etc.,

London, S.W.3, March 27th.

ARCHIBALD LEITCH.

DYSENTERY IN MESOPOTAMIA.

SIR,—Dr. Boney (March 27th, p. 594) claims that I very succinctly proved his case by admitting in my letter (March 20th, p. 545) that all the hospitals in Mesopotamia during the war, except 133 British General Hospital, found the bacillary type of dysentery more prevalent than the amoebic. As this was published by the consulting pathologist it hardly requires proof, and Dr. Boney is hardly justified in calling it his case.

His case appears to be this: that during the war most investigators found the bacillus much more often than the amoeba, and that therefore the recent army report which reverses this order is surprising, not to say incredible.

My point is merely this: that at 133 British General Hospital the amoebae were seen in almost every case of dysentery in 1918, but no bacilli found. This, I consider, makes the recent army report less surprising; and incidentally the opinion formed at Kut is strengthened by the army report. Dr. Boney discards the Kut opinion as isolated, and therefore suggestive of faulty observation. It is certainly less isolated now.

Without in any way implying that Dr. Boney failed to find *E. histolytica* when it was present, I claim that various conditions in different parts of Mesopotamia caused the prevalence of different types of dysentery during the war, and that the change in conditions, as a result of peace, may have again led to a different type of dysentery being prevalent now in the country as a whole.

In support of the Kut findings I should like to add the following:

1. Not only in 1918, but for the two and a half years that the hospital existed at Kut, *E. histolytica* was usually found in dysenteric stools.
2. During that time at least four different men did the bacteriology.
3. Since Kut failed to agree with the majority, the work there

received constant supervision from the consulting pathologist, and each successive worker was warned against reporting the presence of *E. histolytica* unless perfectly sure about it.

4. In 92 cases out of the 141 in which *E. histolytica* was reported the report specially stated "*E. hist. tissue invading*," meaning that the amoebae were seen showing activity and containing red blood cells.

The explanation I put forward was of course "fanciful." It did not claim to be anything else. The adjective "hypothetical" would mean the same thing and sound a little less scathing.—I am, etc.,

Tadworth, March 28th.

B. E. JERWOOD, M.D.

BROMISM: THE SODIUM CHLORIDE TREATMENT.

SIR,—Dr. Semon's memorandum in your issue of February 27th (p. 372) has been of service to me in treating a troublesome case of bromism. I have had a patient whose illness began with a septic tonsillitis and pyorrhoea and continued with an exanthematous or scarlatiniform eruption all over the body, worst in the neck and limbs, which became swollen and then peeled very rapidly. Scarlet fever was soon ruled out, and a second opinion I called in considered the condition one of exfoliative dermatitis. The temperature was round 100° F., and the pulse 90. I had given her some bromide and arsenic and stopped this as soon as the skin began to be troublesome, fearing it as the possible source of irritation. The septic tonsillitis subsided, and the mouth improved after extraction of some decayed teeth and use of hydrogen peroxide.

Thinking the dermatitis was really due to an auto-intoxication, I again gave bromides in small doses, with some Fowler's solution on account of the patient's very "nervy" state. She is 49, but the catamenia are normal. In two days she developed large irritating patches of urticarial eruption all over the body, and these were followed by a host of apparently permanent small warts on the trunk. I stopped the bromide with the first appearance of the second eruption, some three weeks ago. The eruption gradually faded, but in spite of all efforts to eliminate the bromide she continued to feel very weak, irritable, and ill. There was no albuminuria.

After I had read Dr. Semon's suggestion I exhibited sodium chloride, giving cachets gr. x b.d. After five days the patient has made very rapid progress—the depression and weakness are gone, and she is making plans to go away for a change of air before resuming her normal duties.

I think this a noteworthy example of bromism well relieved by sodium chloride.—I am, etc.,

Margate, March 7th.

R. W. NICHOL.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

BEFORE rising on April 1st for the Easter Recess the House of Commons had a second reading debate on the Electricity Bill and commenced the Committee stage of the Economy Bill. The Births and Deaths Registration Bill has been returned with amendments from Standing Committee A, and the Midwives and Maternity Bill is next on the list for examination by that Committee. Important evidence has been taken by the Select Committee on the Registration of Nursing Homes. The Home Secretary has promised to introduce the Factories Bill this session for preliminary examination, and Mr. Chamberlain has invited another debate later about the recommendations of the Royal Commission on National Health Insurance.

National Health Insurance.

During the consideration of the Consolidated Fund Bill, on March 25th, the Liberal party in the House of Commons opened a discussion on the Report of the Royal Commission on National Health Insurance. Sir Kingsley Wood said the Ministry of Health was very grateful to the Commission for valuable suggestions which would increase the efficiency of the National Health Insurance scheme. Neither by the recommendations of the report nor by any Government action was there any likelihood that the health of the nation would be impaired. They had excellent results in health progress, and looked forward confidently to the future. Mr. Rhys Davies, for the Labour party, said he was surprised the Commission did not report in favour of bringing all young persons into the insurance scheme as soon as they entered industry. Young persons should be provided with medical attention from school right through industry to the end of their

days. In school they were attended by medical officers, but between leaving school and the age of 16 all that happened was that they were looked after in a somewhat haphazard manner by the certifying surgeon if they desired to enter a factory.

Mr. Lloyd George said that, on the assumption that the Economy Bill passed into law, he would like to discuss whether benefits would be affected—medical benefits, dental benefits, and maternity benefits—and the question whether a man should be taken to a specialist or the specialist should be brought to him. Everyone agreed that, on the whole and within the powers it possessed, the Ministry of Health had administered the Insurance Act very efficiently, but there was a real need for changes. The proposal of the Royal Commission that suitable medical benefit should be extended ought to receive the earnest consideration of the House. The extension of medical benefit would improve the health of the people, and if a reduction of sickness followed the Government would get a relief in the amount it had to pay. They could not reduce the contributions of the insured person or of the State without placing the whole scheme in jeopardy.

Mr. Chamberlain said it had been recognized from the beginning that one of the principal defects of the National Health Insurance scheme was that the medical benefit provided was insufficient. No change would be more warmly welcomed by approved societies than one which would extend the scope of medical benefit and give insured persons the advantages of expert and specialized advice and treatment. General practitioners themselves, through being brought constantly into touch with these men who had made a special study of particular diseases or particular forms of weakness, would find their interest aroused and stimulated, and their knowledge widened and extended, and therefore even the present medical services under the Act would be improved and strengthened. The report of the Royal Commission showed that this extended medical service at any rate was not affected by the Economy Bill. The financial proposals of the Commission could be effected by a partial pooling, though that was not popular among the approved societies. He suggested that the House should discuss the matter at a subsequent and convenient time.

Answering Mr. D. Grenfell, Mr. Chamberlain said about 3,500 approved societies and branches in England, having a total membership of over 10,500,000 insured persons, had adopted schemes of additional benefits that included payments towards the cost of dental treatment. These numbers were likely to be materially increased from July, when schemes following the second valuation would become operative for societies. Mr. Grenfell asked at the end of 1923. Mr. Grenfell asked whether the Government would take steps to ensure that dental treatment was included in the dentures should be included in the treatment provided under the National Health Insurance Acts. Mr. Chamberlain replied that the Royal Commission on National Health Insurance came to the conclusion that, while a complete dental service for the whole insured population would be eminently desirable, it was not at present financially practicable, and it recommended that the general arrangements for dental services under additional benefit schemes should be continued. Societies and branches having a sufficient disposable surplus on valuation were reminded of the possibility of their adopting dental benefit as an additional benefit, and he proposed that this should remain the practice. The report of the Royal Commission showed that, even if the Government had not decided to reduce the State contribution to national health insurance, it would not have been possible to make dental treatment and the provision of dentures a general benefit under the Act.

Coroners Bill.

The Coroners (Amendment) Bill was again considered in the House of Lords on March 25th, and further amendments were made on the report stage.

On the motion of the Lord Chancellor, a series of amendments were agreed to, the effect of which was to disqualify an alderman or councillor from being a deputy to the coroner appointed by his council.

also agree
appointme
necessary

Coroners Act, 1892, relating to coroners should apply, with the amendment proposed by the Lord Chancellor, to coroners for the King's Household.

An amendment, also proposed by the Lord Chancellor, was made to Clause 20, to provide that a coroner, instead of directing a local medical practitioner to perform a post-mortem examination, might request any legally qualified practitioner to do it. This might, he explained, sometimes be the more convenient course.

Clause 21 deals with the power of a coroner to request specially qualified persons to make post-mortem and special examinations. The Lord Chancellor moved to omit Subsections 2 and 3, which provided that any person who consented to comply with a coroner's request to make a post-mortem or special examination might be summoned as a witness: and that Section 22 of the Coroners Act, 1887, which related to fees payable to medical witnesses, should not apply to any person requested by the coroner under this clause to make an examination, whether he was summoned as a witness or not. His lordship moved to substitute two new subsections. He explained that Subsection 2 was re-drafted, so as to avoid casting any doubt on the power of the coroner under the common law to summon any person he thought fit. Subsection 3 was re-drafted, so as not to legislate by reference to Section 2 of the Act of 1887, and to make provision for the precise fees to be paid. These amendments were agreed to.

An important new clause was inserted, on the Lord Chancellor's motion, after Clause 21. It reads as follows:

"The fees payable to a legally qualified medical practitioner who has made any post-mortem examination by the direction or at the request of a coroner, or who has attended an inquest in obedience to a summons of a coroner under the Coroners Act, 1887, shall (save as in this Act otherwise expressly provided) be as follows, that is to say: (a) for attending to give evidence at any inquest where a post-mortem examination has been made by the practitioner, one guinea; and (b) for

making a *post-mortem* examination of the body of the deceased and reporting the result thereof to the coroner without attending to give evidence at an inquest, one and a half guineas; and (c) for making a *post-mortem* examination of the body of the deceased (including the making of a report, if any, of the result thereof to the coroner) and for attending to give evidence at an inquest on the body, two guineas:

"Provided that no fee or remuneration shall be paid to a medical practitioner for the purpose of a *post-mortem* examination instituted without the previous direction or request of the coroner."

The Lord Chancellor explained that this clause fixed the fees of medical witnesses. The object was to make specific provision as to the amount of fees for a *post-mortem* examination without an inquest under Clause 20 of the bill, and also to re-enact Section 22 of the Act of 1887, with various amendments and omissions, instead of leaving persons to gather the effect of that section and the present section by piecing the two together.

A further amendment was agreed to, on the Lord Chancellor's motion, providing that after the next vacancy in the office of coroner for the City of London the provisions of the bill should apply to the City coroner. He explained that otherwise the City coroner in time would become the only coroner appointed by a local authority and yet be left out of some of the provisions of the ordinary law.

Births and Deaths Registration.

Consideration of the Births and Deaths Registration Bill was resumed in Standing Committee on March 25th. On the motion of Dr. Fremantle, the Committee decided that in London the Common Council of the City or the London County Council, and in the rest of the country the county councils and county borough councils, should be the authorities who should arrange to make available the services of a registered medical practitioner for verifying, at the request of the coroner, the death of any person whose body had not been seen by a registered practitioner since death. A motion that the clause as amended stand part of the bill was, however, defeated by 19 to 7, as the subject is more proper for consideration on the Coroners Bill. Drafting amendments were made at the instance of Dr. Fremantle and Dr. V. Davies in the clause compelling the registration of stillbirths, the word "stillbirth" being substituted for "stillborn child." Other provisions relating to the duties of coroners were deleted on the motion of Sir Kingsley Wood. Sir Richard Luce moved words authorizing the Minister of Health, with the concurrence of the Home Secretary, to make regulations "as to the period of time a body may be retained after death in an inhabited house or other premises." These words, which had been suggested by the British Medical Association, were accepted by Sir Kingsley Wood and the Committee. An amendment was accepted from Sir K. Wood which more precisely defined the "person effecting the disposal" of the body. A new clause for construing the bill when applied to cremations was brought up by Sir K. Wood and added to the bill. The bill then passed through Committee and was put down for report in the House on March 31st.

Registration of Nursing Homes.

The Select Committee on the Registration of Nursing Homes met a first time at the House of Commons on March 25th.

Those summoned to attend as witnesses on that day were Mr. L. G. Brock, principal assistant secretary, Ministry of Health; Mr. M. L. Gwyer, legal adviser to the Ministry of Health; and Miss Rundle, secretary of the College of Nursing.

Mr. Brock, in his précis of evidence, announced that the information available in the Ministry was insufficient to justify the expression of any definite view for or against the registration of nursing homes. The Minister had not received any representations from local authorities, nor from associations of local authorities, suggesting that registration demanded the attention of Parliament. The Minister neither advocated registration in principle, nor would he oppose it, if the committee decided that, from the point of view of public health, the advantage was in favour of registration. It was sometimes alleged that there was a case for supervision of nursing homes in the interests of morality. That was a question for the Home Office and the police, not for the Ministry of Health. No local authority, so far as was known, had any power to inspect nursing homes as such, but various authorities had power to inspect maternity homes, and could, in fact, inspect any home receiving maternity cases. The Midwives and Maternity Homes Bill introduced by Dr. Fremantle had the sympathy of the Minister of Health. The Minister thought there was a special case for inspecting maternity homes. Without a power to the supervising authority under the Midwives Acts to inspect such homes there was a real danger of the employment in the less reputable homes of unqualified women as midwives. Maternity homes of a certain type were resorted to by women about to be confined of illegitimate children. In such cases there was no one with any motive to see that at birth the child was given a fair chance of life, and apart from carelessness or deliberate negligence these so-called homes might be used for baby farming. He pointed out that other nursing homes existed for the reception of acute surgical and medical cases, for the reception of cases with nervous trouble, and for the reception of chronic senile or paralytic cases. In all three types of home patients needed more or less constant attention, and were not fully able to look after themselves. The function of the first type of nursing home was substantially that of the hospital, and the second type was very near the mental hospital receiving voluntary boarders. All three types differed from hospitals in being carried on for gain, but there were homes for the reception of senile paralytics which were partly charitable, but were perhaps more in need of inspection than many homes conducted on business lines. The Ministry therefore suggested that if registration of nursing homes was recommended the definition should include any premises intended

to be used for the reception of persons suffering from any sickness, injury, or bodily or mental infirmity for the purpose of providing such persons with nursing where any payment or reward was made or promised by or on behalf of any person so received. Local authorities might be given power to exempt any home which they were satisfied was *bona fide* conducted for charitable purposes. The witness pointed out that in homes for nervous cases, in the absence of inspection by responsible authority, patients might be kept after certifiable mental disorder had developed. Cases of suicide by patients described as suffering from nervous-breakdown, and under treatment in nursing homes, suggested that in this special type of home there were grounds for inspection which did not apply to other types. Turning to the case against supervision of nursing homes, the witness pointed out that the real responsibility of seeing that the patient was properly looked after rested with the doctor, who was bound to be in regular attendance. It was against the interest of the doctor to send patients to an unsatisfactory nursing home. The provision of nursing homes was a legitimate industry meeting a real need, and the Minister was bound to say that the evidence in his opinion would not establish any widespread existence of abuses. There was at present no demand by local authorities for power to supervise. Supervision and the imposition of statutory requirements in regard to the qualification of the nursing staff would tend to increase the cost of treatment in nursing homes, which was already high, and in some cases almost prohibitive.

A statement submitted by the College of Nursing in favour of registration declared that many homes were not managed in a satisfactory way, and that the number of such homes was increasing. The College was of opinion that the prestige of nursing homes could only be safeguarded by a system of State registration. It suggested that inspection should be by a registered nurse, with or without a medical practitioner. Agreement with the principle of registration had been expressed, said the statement, by the British Medical Association, the Society of Medical Officers of Health, the County Councils Association, and other bodies.

Mr. Gwyer and Mr. Brock were examined together on the memorandum prepared by the Ministry of Health. They stated that the Ministry had no evidence to show how many maternity homes were run as separate businesses. Dr. Shiels asked whether the Midwives and Maternity Homes Bill introduced by Dr. Fremantle, and now before Parliament, might not overlap the ground proposed to be covered by the Nursing Homes Bill which had been introduced last year. Mr. Gwyer said this was possible, and that if either bill passed before the Select Committee reported the researches of the Committee would be useless. Mr. Gwyer said the Ministry could only give two instances where charges had been brought against nursing homes other than maternity homes. The Chairman of the Committee, Sir Cyril Cobb, asked whether it was the case that the Ministry had little information that would guide the Committee on the desirability of registering nursing homes. The witness admitted that this was the case. Miss Wilkinson asked the opinion of the Ministry on the suggestion made by the College of Nursing that the chief of a nursing home should always be a registered nurse. Mr. Gwyer said there were so many registered nurses available that such a condition appeared needless. He knew of one thoroughly qualified but unregistered woman conducting a nursing home who would not receive a licence under the bill presented last year, although doctors were eager to send patients to her. The Committee adjourned till March 30th.

Factories Bill.

On March 26th Miss Wilkinson moved the second reading of the Factories Bill. This measure was prepared by Mr. Arthur Henderson when Home Secretary. Miss Wilkinson said it was to consolidate and amend the enactments relating to factories. It dealt with health, safety, welfare, accidents, industrial diseases, and the employment of women, young persons, and children. It proposed to increase the air space for each worker from 250 to 400 cubic feet, and made new provisions in regard to lighting, heat, sanitation, and cleanliness. No man should carry on business if he could not ensure his workers a reasonable standard of health.

Captain Macmillan moved that the House, while recognizing the need to introduce a Factories Bill this session, should reject the present one as being a proper subject for a private member's bill. He said the Minister of Labour on achieving an agreement on hours of labour, and hoped that the hours of women and young persons would be regulated without reference to any international agreement.

The Home Secretary said that nineteen-twentieths of Mr. Henderson's bill would be included in the Government's Factories Bill. The Prime Minister and Cabinet authorized him to say that this bill would be introduced this session for discussion and reintroduced early in 1927 as one of the principal measures of that year. The Government would then do its utmost to pass the bill into law. The Government bill would not include the Labour party's proposals against night baking, but it would abolish the distinction between textile and non-textile factories, as also between factories and workshops. His bill would deal with overcrowding, temperature, and lighting in factories, sanitary conveniences, the provision of water, of first-aid outfits, and of special clothing, and would secure protection against dust and safeguards against the lifting of undue weights. Factories of trades where there was exceptional liability to disease would have special medical supervision.

Dr. Vernon Davies objected to Miss Wilkinson's bill allowing certifying factory surgeons to be appointed by local authorities as well as by the Home Office. That was a retrograde step, and

might lead to a conflict of opinions on factory conditions. The Home Office should make all these appointments and standardize the system. Dr. Watts referred to shuttle-kissing as still being one of the greatest dangers to health in the cotton mills, and thought that the bill did not provide enough security against the danger from the practice. He also argued in favour of a unified factory medical service. Dr. Fremantle complained that the bill did not provide for a staff of Home Office medical officers to collaborate with the officers of the Ministry of Health. Captain Macmillan's amendment being carried by 184 to 109, Miss Wilkinson's bill failed to secure a second reading.

Artificial Sunlight.—Mr. Chamberlain told Sir Harry Brittain that he had no complete information on the number of hospitals in this country in which artificial sunlight treatment was provided, but arrangements for this treatment had been approved, in connexion with tuberculosis and maternity and child welfare schemes, in twenty-six hospitals and sanatoriums, exclusive of tuberculosis dispensaries and maternity and child welfare clinics. Reports on the approved schemes were being considered by the Ministry of Health. The treatment, if appropriately applied, was undoubtedly beneficial in many cases, but he was not yet able to give a complete reply to the question whether the treatment was proving successful.

Encephalitis Lethargica.—In answer to Mr. Briant, Mr. Chamberlain circulated statistics showing that in England and Wales, including port sanitary districts, 454 cases of encephalitis lethargica were notified in 1922; 1,025 in 1923; 5,039 in 1924; and 2,635 in 1925, the last figure being provisional.

Hertford Hospital, Paris.—Mr. A. M. Samuel informed Sir Richard Luce that the medical staff of the Hertford British Hospital, Paris, resigned in November, 1924. They had been replaced and no action by the British Government appeared necessary.

Bethlem Royal Hospital.—Objection was again taken to the second reading of the Bethlem Hospital Bill when this was moved in the House of Commons on March 29th.

Notes in Brief.

On January 1st, 1926, the persons in receipt of Poor Law relief in England and Wales were 1,441,500, compared with 1,205,267 a year previously.

The Minister of Health has extended till the end of April the time during which he will receive representations on the draft Order proposed to be made under the Milk and Dairies Act, 1915.

Sir Austen Chamberlain states that so far as he knows no foreign Power has yet ratified the Opium Agreement and Dangerous Drugs Convention, signed at Geneva in February, 1925. The agreement will come into force on the ninetieth day after the receipt in Geneva of ratifications by two Powers.

Universities and Colleges.

UNIVERSITY OF OXFORD.

ROBERT JAMES BROCKLEHURST, B.M., M.A., of University College (formerly scholar), and of St. Bartholomew's Hospital, has been elected to a Radcliffe Travelling Fellowship of £300 for two years. Bernard Thomas Quives, exhibitor of University College, student of medicine, has been elected to a Christopher Welch Research Scholarship of £100 for four years.

At a congregation held on March 27th the degree of Bachelor of Medicine (B.M.) was conferred on R. H. B. Bettington.

UNIVERSITY OF LONDON.

At a meeting of the Senate on March 24th regulations were adopted for the award of the recently established Laura de Saliceto studentship for the advancement of cancer research.

It was resolved to institute an academic diploma in anthropology. Sir Holburt Waring was appointed the representative of the University at a meeting to be held next month to consider the steps which should be taken to organize an appropriate celebration in April, 1927, of the centenary of the birth of Lord Lister.

The appointment of obstetric house-surgeon at the Royal Northern Hospital has been approved by the Senate of the University of London for the purposes of the M.D. examination (Branch IV).

UNIVERSITY OF LIVERPOOL.

THE following candidates have been approved at the examinations indicated:

FINAL M.B., CH.B.—Part I: T. Blezard, H. C. Calvey, F. R. Craddock, L. de Jongh, Lillian W. Edwards, E. E. Glenton, L. S. Goldman, A. W. Green, R. E. Hughes-Davies, Edna Morris, T. C. Newman, Alfred S. Roberts, J. B. Rushon, E. P. Thompson, J. L. Walker, A. J. Walsh, Joan Watkins. **Part II:** L. de Jongh, T. Lotter, J. H. Rowlands, J. L. A. Webster.

DIPLOMA IN TROPICAL MEDICINE.—W. J. Aitken, A. Ashworth, R. N. Bansikar, N. Bligh-Peacock, Elsie G. Bolton, E. H. Goodrie, M. A. B. Brito-Mutunavagau, T. Cullen, H. N. Davies, B. G. V. Dias, E. G. A. Doh, H. P. Powrie, Isabella J. Fowler, Katharine M. Hodgkinson, H. Jackson, R. H. Kamakaka, D. Tennor, A. W. Lewis, A. G. Mackay, N. McLean, M. Macneaney, S. B. Malik, M. E. Merchant, E. D. Molony, S. G. Nashikkar, F. Oppenheimer, F. S. Paterson, L. D. Quigley, M. Rodriguez, S. A. Sachdev, H. Singh, J. Singh, S. A. Talib, Yama, C. Tan, Catharine F. Taylor, N. S. Turnbull, B. K. Vardja, T. N.

DIPLOMA IN TROPICAL HYGIENE.—G. Clark, Ivy Collier, B. L. Davis, A. J. Hawe, D. M. Mackay, D. A. Skan.

DIPLOMA IN MEDICAL RADIOLOGY AND ELECTROLOGY.—J. H. Barrett, R. Herndon, J. M. Hosey, Irene E. Kenworthy, H. McE. Morris, D. Ramage.

UNIVERSITY OF EDINBURGH.

At the graduation ceremonial held on March 25th the degree of D.Sc. was conferred upon Dr. Ronald Gray Gordon (physician to the Royal Mineral Water Hospital, Bath) for his thesis on "Personality"; and the degrees of M.B., B.Ch. upon Roderick Macdonald.

UNIVERSITY OF ABERDEEN.

At the graduation ceremony on March 24th the following degrees and diplomas were conferred:

L.D. (honoris causa).—Dr. Robert Wm. Reid, Professor of Anatomy, University of Aberdeen.

M.D.—Alexander Lyall, Charles Reid, Charles W. Walker, Alexander A. McIntosh Nicol, Adam A. Turner.

M.B., Ch.B.—The names of the successful candidates were published in our issue of last week (p. 638).

D.P.H.—J. F. Davidson.

* Awarded honours for thesis.

The following prizes were also presented:

Fife Jameson Memorial Gold Medal in Anatomy: G. A. G. Mitchell. Keith Gold Medal for Systematic and Clinical Surgery: G. Stephen. Shepherd Memorial Gold Medal for the Principles and Practice of Surgery: T. B. Anderson. Dr. James Anderson Gold Medal and Prize in Clinical Medicine: T. E. Anderson and Victoria C. Enslie (equal). Matthews Duncan Medal in Obstetrics: A. W. Forrest and W. Marshall (equal; silver medal each). The Alexander Ogston Prize in Surgery: G. I. M. Gleton. Dyce Davidson Memorial Gold Medal in Materia Medica: M. G. Gibb.

UNIVERSITY OF DUBLIN.

SCHOOL OF PHYSIC, TRINITY COLLEGE.

THE following candidates have been approved at the examinations indicated:

FINAL M.B., PART I.—Materia Medica and Therapeutics; Medical Jurisprudence and Hygiene; Pathology and Bacteriology: R. R. Woods, M. F. N. Griffin, T. C. M. Corbet, M. Gerber, E. G. M. Montgomery, I. Isaacson, S. R. Elmes, R. W. T. H. Stewart, H. Dundon, H. A. Ferguson, J. M. McElligott, L. R. Bramberg, I. F. Rathaus, W. F. Knobel, J. K. Harper, C. F. Cope.

PART II.—Jurisprudence: H. O. Clarke, A. J. Conlin, E. H. Hall, P. F. Palmer, G. A. Wainwright, T. J. W. Keown, W. C. G. Potts, J. M. Solkon, E. W. Blugham, M. A. W. Roberts, Nancie N. Lowther, A. E. A. O.

PART III.—Physiology and Pathology: H. J. Roche, D. N. Power, J. H. M. Lean, Margaret W. Pike, Mary S. Miller, R. G. Kears, J. N. S. Gouws, J. V. Pincus, W. Russell, H. Wilson, G. A. A. Powell, Lucy E. R. Pigott, Mabel E. Brittain, C. G. Nel, G. T. L. Archer, A. B. Brooks, W. C. Sloan, J. F. MacManon, W. G. Maule, A. Sachs, C. L. Taylor, W. Magowan. **Anatomy:** E. E. Malou, E. E. Satchwell, S. Smyth, D. St. C. Mackenzie, H. A. Ferguson, J. Quigley, J. B. Patrick, C. F. M. Wilson, M. G. J. Booyssen, Norah E. Fenton, J. Johnston, N. J. U. Mather, W. P. Culbertson.

DIPLOMA IN GYNAECOLOGY AND OBSTETRICS.—I. V. Yoffa.

* Passed on high marks.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

AN extraordinary comitia of the Royal College of Physicians of London was held on Monday, March 29th, at 5 p.m., the President, Sir Humphry Rolleston, Bt., being in the chair.

The President delivered the annual address, which was much appreciated of the large amount of business before the meeting was made to the changes made in the Membership. Brief obituary appreciations of fellows who had died during the year, Tooth, Sir Richard Douglas Powell, Dr. J. W. Russell, and Dr. G. H. Hunt, the retiring President, Sir Humphry Rolleston, was moved by Dr. Mitchell Bruce and carried.

The College then proceeded to the election of President. At the first ballot Sir John Rose Bradford received 51 votes, Lord Dawson 37, Sir William Hale-White 19, Dr. Raymon Crawford 14, and Dr. John Fawcett 11. The first two of these names were then submitted to a further ballot, when Sir John Rose Bradford received 81 votes and Lord Dawson 65. Sir John Rose Bradford was then inducted to the President's chair.

Dr. R. O. Moon was elected Assistant Registrar, having been nominated by the President at the last meeting of the comitia.

Dr. J. Walter Carr was elected a representative of the College on the Professional Classes Aid Council, in place of Dr. Newton Pitt, retired.

A resolution of the Royal Society asking the College to attend a meeting in the Society's purpose of organizing a celebration of Lord Lister (April 5th, 1927). The President was appointed.

Diplomas in Tropical Medicine were granted to 27 candidates. (The names were published in the report of the meeting of the Council of the Royal College of Surgeons of England, printed in our issue of March 20th, p. 552.)

Lord Dawson drew attention to the discontinuance of the publication of *Medical Science Abstracts and Reviews*. The College affirmed its appreciation of the value of this publication, and the hope was expressed that the Medical Research Council would resume it.

Obituary.

DR. THOMAS HORNE, who died on March 8th, at the age of 75, was one of the senior members of the public health service. He received his medical education at Anderson College, Glasgow, where he obtained the diplomas L.R.C.P., L.R.C.S.Ed., and L.M., in 1874, graduating M.D.Durh. in 1892. After holding the post of medical officer of health for Sandwich he went to Stockton-on-Tees, and for twenty-nine years devoted himself to improving the health of the town. The control of infectious diseases first engaged his attention, and after several years' activity he had the satisfaction of seeing a considerable measure of success result. Another reform achieved after persistent effort was the conversion to the water carriage system of the numerous privy middens in the town. Dr. Horne was long handicapped by ill-health, which compelled his retirement two years ago, when he was appointed consulting medical officer of health for the borough. For a short period he was temporary medical inspector under the Local Government Board. He was for many years a member of the British Medical Association.

Dr. JOHN STEWART HENDRIE, who was killed accidentally on March 8th, at the age of 23, while on his way to an urgent case, was educated at Galston Higher Grade School, Kilmarnock Academy, and Edinburgh University, where he graduated M.B., Ch.B. in June, 1925. He obtained a British Medical Association Prize for an essay on the diagnosis and treatment of chronic intestinal obstruction in the preceding April. He became assistant to Dr. John Brown at Durham in October, and during his short professional career won much popularity. Much sympathy is felt for his mother and two brothers in their sad bereavement.

The following eminent foreign medical men have recently died: Dr. Van de Vloete of Brussels, formerly president of the Société de Neurologie Belge; Dr. Juan B. de Landeta, doyen of the medical profession in Havana; Professor Serafino Patellini-Rosa, professor of social eugenics in the University of Milan.

Medical News.

THE Fellowship of Medicine announces that on April 15th, at 2 p.m., Mr. W. E. Tanner will give a clinical surgery demonstration at the Prince of Wales's General Hospital, Tottenham, free to members and general course ticket-holders of the Fellowship. From April 19th to May 1st the Bolingbroke Hospital, Wandsworth Common, will hold an intensive course in medicine, surgery, and the specialties. During May there will be two courses lasting the entire month: a course in psychological medicine at the Maudsley Hospital, Denmark Hill, will include lectures on the psychoneuroses, crime, and insanity, and a clinical course in venereal diseases at the London Lock Hospital. From May 3rd to 22nd there will be a clinical and an operative course at the Central London Throat, Nose, and Ear Hospital. The Royal Waterloo Hospital will hold a course in medicine, surgery, and gynaecology from May 3rd to 22nd, and from May 3rd to 15th the Infants Hospital will hold an afternoon course under the direction of Dr. Eric Pritchard. A three weeks' course will be given by the Royal Westminster Ophthalmic Hospital from May 3rd to 22nd. Copies of all syllabuses and of the general course programme may be obtained from the Secretary of the Fellowship of Medicine, 1, Wimpole Street, W.1.

A NUMBER of members of the International Society of Medical Hydrology will visit the spas of Czechoslovakia in the middle of April, and other medical men are invited to join the party, which will leave London on Wednesday, April 14th. Medical discussions will be held at Karlsbad on April 16th and at Marienbad on April 17th. The party will be officially received at Prague on April 19th, and there will be a special conference on rheumatism at Pístany, in which Sir William Willcox (London), Dr. Kahlmeter (Sweden), Dr. van Breemen (Amsterdam), Professor Strasser (Vienna), Professor Netousek (Bratislava), and Dr. Baltaceanu (Budapest) will take part. Visits will also be paid to spas in the Tatras mountains. Members of the party will be guests of the Czechoslovakian Government and of the various spa

municipalities. Full particulars can be obtained from the Honorary Secretary of the International Society of Medical Hydrology, 36, Devonshire Place, London, W.1; application must be made not later than the first post on Monday, April 5th.

ON March 23rd a large silver loving-cup, suitably inscribed, was presented to Lieut.-Colonel A. Alcock, C.I.E., F.R.S., LL.D., by his colleagues at the London School of Hygiene and Tropical Medicine, where, until his recent resignation, he had been director of entomology since 1907. Dr. Andrew Balfour expressed the indebtedness of the school and its students to Colonel Alcock, and referred to the valuable scientific results of his work.

THE twenty-first international post-graduate course will be held in Vienna, from June 14th to 27th, and will deal with tuberculosis, with special reference to treatment. From June 28th to July 3rd there will be a series of practical courses. Applications for membership should be addressed to the secretary of the international post-graduate courses, Dr. A. Kronfeld, Porzellangasse 22, Vienna IX, from whom further information may be obtained.

A TOUR for medical practitioners to the spas and climatic health resorts of Italy is being arranged for September 12th to 28th, and will be conducted by Professor Guido Ruata. The general arrangements will be similar to those of the tours of 1924 and 1925, and the places to be visited include Abbazia, Portorose, Grado, Venice, Merano, Bolzano-Gries, Riva, and Salsomaggiore. Medical lectures will be given at each resort. The party will be limited to 200, but each medical practitioner may be accompanied by a relative if early notice is given. The cost of the tour from its commencement at Abbazia to Salsomaggiore is 1,600 lire, and further information may be obtained from the Ente Nazionale Industrie Turistiche, 6, Via Marghera, Rome.

THE International Society for the Protection of Childhood will hold its fifth session at Rome on May 25th, when the following subjects, among others, will be discussed: situation of children in the colonies, prophylaxis of tuberculosis in families, prophylaxis of rickets, and the statistics of infantile mortality.

THE following appointments have recently been made in the French faculties of medicine: Dr. G. Portmann, professor of oto-rhino-laryngology, in succession to Professor Moure, at Bordeaux; Dr. Desoil, professor of medical and pharmaceutical zoology at Lille; and Dr. Laporte, professor of medical pathology at Toulouse.

Dr. DEAN LEWIS, professor of clinical surgery in the State University of Chicago and editor of the *Archives of Surgery*, has been nominated professor of surgery in the Johns Hopkins University in succession to Professor W. S. Halsted.

JOHN WRIGHT AND SONS, LTD., of Bristol will publish in May the first number of the *Cancer Review*, under the direction of the British Empire Cancer Campaign, 19, Berkeley Street, London, W.1. This journal will be devoted entirely to reviews and abstracts of current publications in all countries and languages, dealing with tumours in general and malignant new growths in particular. The abstracts will be arranged under two main headings: (1) General, including experimental and biochemical work on cancer, culture *in vitro* of malignant tissues, association of tumours with parasites and other irritants, pre-cancerous conditions, physiological changes associated with malignancy, radiological and other methods of diagnosis and treatment, prognosis, epidemiology, and statistics; (2) Clinical and regional, including publications on the clinical pathology of tumours of the various organs and systems of the body. Ten numbers will be published each year. Subscriptions (50s. a year) may be sent to the publishers, or to any bookseller.

A PAMPHLET of twelve pages, *The Problem of the Intoxicated Motor-driver*, has been issued, at the price of 2d., by the True Temperance Scientific Committee, Donington House, Norfolk Street, Strand, W.C.2. The pamphlet is signed by Sir James Crichton-Browne, Sir W. J. Simpson, Drs. H. Wansey Bayly, W. H. B. Stoddart, H. W. Southgate, and Mr. Ernest E. Williams. Three aspects of the problem are discussed—the legal, the scientific, and the social—and detailed reference is made to the paper by Drs. Southgate and Carter, published in the *BRITISH MEDICAL JOURNAL* of March 13th, 1926, on the excretion of alcohol in the urine as a guide to alcoholic intoxication. We may recall here that a representative committee on tests for drunkenness was appointed last year by the British Medical Association, and is now engaged on its inquiry.

APPLICATIONS for the Dickinson Research Travelling Scholarship in medicine, value £300 for one year, and for the Dickinson Pathology Scholarship, £75 for one year, must be sent in by May 1st to Mr. F. G. Hazell, secretary to the trustees, Manchester Royal Infirmary, from whom copies of the regulations governing the scholarships can be obtained.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the **BRITISH MEDICAL JOURNAL** alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the **BRITISH MEDICAL JOURNAL** must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the JOURNAL, should be addressed to the Financial Secretary and Business Manager.

The TELEPHONE NUMBERS of the British Medical Association and the British Medical Journal are **MUSEUM 9861, 9862, 9863, and 9864** (internal exchange, four lines).

The TELEGRAPHIC ADDRESSES are:

EDITOR of the **BRITISH MEDICAL JOURNAL**, *Ailology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Mediscera Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 4737 Dublin), and of the Scottish Office, 6, Drumshough Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 4361 Central).

QUERIES AND ANSWERS.

STATIC ALBUMINURIA.

"F.R.C.P." asks for advice in treatment to cure static albuminuria. After searching many books he finds little to guide him. Of course, prolonged rest cures for the time, but patients cannot be kept indefinitely in bed.

SODIUM CHLORIDE.

"W.G." asks to salt (sodium chloride) writes, of B. suspect that some present-day physiologists state that we eat too much salt. Does an excessive intake of salt cause any harmful condition in an otherwise healthy individual?

* * We have referred this question to our pharmacological adviser, who writes: I do not know of any evidence to show that a moderate excess of sodium chloride is unhealthy provided that the kidneys are normal. If the kidneys are diseased they often lose the power of excreting chlorides, and then excess of NaCl produces oedema. Excess of NaCl can produce oedema in infants, but this is not of any practical importance, as the amounts needed are larger than are likely to be taken. I do not know of any injurious effects that have been shown to follow the taking of large amounts of NaCl in the diet of normal individuals.

TREATMENT OF LIPOMATA.

DR. R. CLARK WAKEFIELD (Milby, Seine-et-Oise) writes in reply to Dr. A. Y. Massouda (Cairo):—In *Erichsen's Surgery*, eighth edition, we read: "It is true that we have the sanction of Sir B. Brodie's high authority for the administration of the liquor potassae in some cases, under which treatment this eminent surgeon states that fatty tumours have occasionally disappeared. I tried it on one case of a lipoma of the upper arm, left, size of an orange. It quite disappeared under 20-drop doses of liq. potassae in small tumbler of water three times a day. This patient declined any surgical help."

INCOME TAX.

Motor Car Replacement and Depreciation.

"J. McE." replaced a car in 1923; the new car cost £525, of which he was allowed to deduct, as a net expense of renewal, £320. In computing his assessment for (apparently) 1926-27 the Inspector has taken into account the depreciation allowance for 1923-24 on the written-down value of the car, taking the original value as £520.

* * "J. McE." may be referred to the reply to A, B, and C in our issue of March 13th. In his case we are of opinion (1) that the Board of Inland Revenue is not likely to insist on the proposed partial cancellation of the renewal allowance, and (2) that his depreciation allowance for 1926-27 should be calculated as follows:

Original cost of car in 1923	£	525
Depreciation for 1924-25 at 20 per cent.	105	
	420	
Depreciation for 1925-26 at 20 per cent.	84	
	336	
Depreciation for 1926-27 at 20 per cent.	67	

Our correspondent should bear in mind that when he renews the present car he can claim, as an obsolescence allowance, the net cost of replacement less the depreciation allowances to which effect has been given.

Replacement of Car.

"J. A. S." has written to the Board of Inland Revenue, as suggested in our issue of February 27th, and has received in reply an intimation that while the matter is primarily one for the adjudication of the District Commissioners, the Board holds the view that the amount to be allowed "is the excess of the cost at the date of replacement of a car similar in type to the old car—so far as this may be ascertainable—over the price realized by the sale of the old car."

* * On this basis a fall in the general level of motor car prices results in an allowance which is insufficient to cover the original outlay on the car. Nevertheless, the view taken by the authorities is, in our opinion, one which the courts would not be likely to overrule, and consequently we cannot advise "J. A. S." to take the matter to appeal before the District Commissioners: the risk of ultimate expense is too heavy for the object sought. The matter would be of considerable general importance were it not for the alternative depreciation allowance which is now obtainable for cars; where the allowance is claimed in lieu of the cost of replacement the inequitable result of falling prices does not apply.

LETTERS, NOTES, ETC.

CAUTION.

SOME inquiries have recently been received from members who have had begging letters from a Mrs. E. M. Etheridge, described as of Taunton. Members who receive further letters of the kind might, before giving assistance, be well advised to communicate with the secretary of the Charity Organization Society, Denison House, 296, Vauxhall Bridge Road, London, S.W.1.

A DISCLAIMER.

DR. G. MURRAY LEVICK (London, W.) writes: I have received cuttings from certain lay newspapers in which reference is made to "research work" carried out at the British Humane Association Artificial Light Clinic at Westminster in connexion with the mental deficiency. Will you allow me, the **BRITISH MEDICAL JOURNAL**, to disclaim any responsibility for such statements? No such research work has taken place at the clinic, of which I am in honorary medical charge.

WASTE OF COAL AND LOSS OF HEALTH.

"A. Y." writes: I consider that your article in the JOURNAL of March 20th (p. 537) is a masterly exposition on the madness of the present system of using coal in this country. If some such paragraph could be published in every newspaper in the country with the authority of the British Medical Association behind it, in order to rouse public opinion, so that determined action may be taken, then the whole outlook for the trade and prosperity of this country will be changed.

THE BATHS OF SALSOMAGGIORE.

PROFESSOR C. CATTANEO contributes to the *Salsomaggiore Terme* for November-December, 1925, a discussion of the value of the waters under certain conditions. He reports that among 1,000 cases there 26 per cent. were cured, 65 per cent. benefited, and 9 per cent. remained without improvement. The greatest advantage was derived by patients with tertiary syphilis, in whom 43 per cent. of cures was reported, all the remaining patients showing some improvement. In bone and joint tuberculosis 42 per cent. of the cases were cured, 50 per cent. improved, and 8 per cent. were unaffected. The proportion of cures in various other groups of disease is given as follows: skin diseases, 40 per cent.; anaemias, 37 per cent.; neuritis, including sciatica, 34 per cent.; sequelae of wounds and the menopause, 33 per cent.; chronic non-tuberculous conditions of the respiratory tract, 32 per cent.; sequelae of pleurisy and peritonitis, 31 per cent.; and rhino-pharyngitis, laryngitis, and otitis, 30 per cent. No cures were obtained in diseases of the veins and lymphatics, but improvement was shown by most patients. In disordered metabolism and uricæmic arthritis there was 73 per cent. improvement. Professor Cattaneo concludes that, although the waters of Salsomaggiore cannot be considered a panacea, yet their therapeutic action is considerable in a large number of conditions. He believes that a still higher percentage of cures would be obtained if repeated courses of treatment were undertaken by those who derive benefit from a single course.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 39, 42, and 43 of our advertisement columns, and advertisements as to partnerships, assistantships, and locum tenencies at pages 40 and 41. A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 112.

Lumleian Lectures ON ENDOCARDITIS.

BY
SIR THOMAS HORDER, Br., K.C.V.O., M.D.,
PHYSICIAN TO ST. BARTHOLOMEW'S HOSPITAL.

LECTURE II.*

NON-MICROBIC ETIOLOGICAL FACTORS IN THE PRODUCTION OF ENDOCARDITIS.

I PASS now to consider certain etiological factors in the production of endocarditis, both of the valve cusps and of the chambers of the heart, which, though the exclusion of a chronic infective element must only be presumed at any time with great caution, appear to be outside the sphere of microbic activity.

Having spoken of the possibility of *congenital defects* in connexion with some cases of pure mitral stenosis I will take these first. It has been for a long time held that congenital defects in the heart are almost confined to the right side of this organ. Such defects as are found in the left side, if we except those gross defects which lead to such massive disturbances of the circulation that there are early and lethal results, have been too lightly passed over. There is good reason to believe that we have been too cavalier in our observations concerning the intimate anatomy of the heart valves, and of the aortic valve in particular, in relation to endocardial disease. Deviations from the normal in these delicate structures may well prove to be a determining factor in infection of a grade hitherto unsuspected. This possibility did not escape the eyes of older observers. Thayer reminds us that the recognition of the fact that bicuspid aortic and pulmonary valves predispose to disease is as old as Paget. Osler also pointed out the liability of these malformed segments to sclerotic endocarditis. Of seventeen cases examined by him all presented sclerotic changes, and the majority of them had, during life, the clinical features of incompetence.

Glynn, who gave the Lumleian Lectures upon infective endocarditis in the year 1903, refers in detail to a specimen obtained from a man aged 48 years, in which one of the two cusps was found to be torn and everted, and whose fatal illness started after a strain, during which it is presumed that the diseased cusp was damaged. I pointed out in 1909 that congenital defects that were compatible with good health and were outside the category of those grosser lesions which were to be recognized during life might still be of great importance in inducing active endocarditis. I cited cases of this as illustrated by defective inter-ventricular septum and patent ductus arteriosus, in patients of 31 and 42 years of age respectively. I drew special attention to the association of bicuspid aortic valves with bacterial endocarditis in 1905 when publishing the first cases of endocarditis due to Pfeiffer's bacillus. In 1909 I dealt with this point more fully, having found bicuspid aortic valves in two other hearts in the museum of St. Bartholomew's Hospital, each the site of bacterial endocarditis. In still a fourth specimen, from a case of pneumococcal endocarditis, the pulmonary valve cusps were only two in number. Since that date four other hearts have been added to the museum, all showing bicuspid aortic valves, and all affected by bacterial endocarditis. In addition, Dr. T. H. G. Shore, the curator, possesses three unmounted specimens of a similar kind, which he obtained from soldiers dying of this disease in France. It is very clear that the condition here dealt with is one of considerable importance.

In 1923 Lewis and Grant contributed a valuable paper to *Heart*, in which they treated of the normal structure of the aortic valve and especially of the relations of the aortic media to the annulus fibrosus. They describe in detail four cases of the condition of bicuspid aortic valve and seven further cases associated with bacterial endocarditis. There follows an analysis of 116 cases collected from the literature. Of these, 63 were males, 20 females, and in 33 cases the sex was not stated. These authors estimate that no fewer than 23 per cent. of males reaching

adult life, and possessing congenitally bicuspid aortic valves, die of active endocarditis. The moral of all this is, as Libman remarks, that it behoves us to be much more critical than we have hitherto been in our examination of diseased hearts in the dead-house. Interpretations of our findings must needs be very cautious since the matter is by no means easy. We must endeavour to distinguish (a) true congenital defects, (b) the sclerotic residua of effete infections by rheumatism, (c) the results of healed bacterial infection, and (d) sclerosis from purely mechanical causes. With so many possibilities before us it is obvious that the task is full of difficulties. I shall return to this matter in dealing with questions relating to pathogenesis.

PHYSICAL AND EMOTIONAL STRESS.

But if we have been cavalier in our consideration of these congenital defects and the anatomical strain which they impose upon these delicate structures, situate as they are at the very centre of the hydraulics of the circulation, may we not also have been somewhat cavalier in regard to *strain* of a functional kind? It has been the custom of late years to minimize the factor of physical and emotional stress in general in cardio-vascular disease, and therefore it has been largely discounted in the production of endocardial changes. This is a material age, and we have become accustomed to discount functional elements in the etiology of organic disease. We have been told that the healthy heart cannot be damaged by volitional effort. But whose heart is "healthy"? If a heart is found to be damaged after effort, then the onus of the damage is laid at the door of toxic agencies. But are we not all of us potentially, if not actually, "toxic"? And if this be so, does the doctrine of the heart's immunity from self-imposed strain carry any more practical application than that it is desirable, in order to reduce the effect of the strain to a minimum, that we should see to it that we are as little "toxic" as possible?

It is necessary to distinguish between sudden and occasional strain on the one hand and prolonged strain on the other. There seems good reason for believing that both physical and emotional strain, if prolonged, may lead to endocardial disease, both of the sclerosing variety and, with or without this, of the active bacterial type. Since prolonged strain is inseparable from *fatigue*, this element may also be included in this group of etiological factors.

The recent experiences of those who have had charge of ex-soldiers suffering from endocarditis of the bacterial sort throws much light upon this matter. Reports concerning these cases are to hand from careful observers in nearly all the belligerent countries, but are not yet complete in many important points. So far as the observations go, however, we have strong confirmation of the view taken here. The cases reported have been almost entirely aortic in disposition, there has for the most part been no evidence of previous disease of the valves, and the type of soldier affected, and his war record, suggest strongly that the factor of strain has been considerable. In this country Starling and Carey Coombs have made memorable contributions on the subject. Starling, in a report on fifty-two cases of infective endocarditis in ex-soldiers, in half of which the disease was of the chronic type, says of them:

"the disease occurs in individuals of fine health and physique who have had little or no previous illness. The majority of those suffering from it have undergone a considerable degree of physical stress—e.g., those who were serving in the fighting line in the years 1916-17. The infection is primary in the endocardium. The *post-mortem* appearances show no evidence of previous rheumatic endocarditis."

Carey Coombs, in his equally important paper, is led to almost identical conclusions. He says, as the result of his analysis of thirty cases of post-war chronic endocarditis of the bacterial type:

"the predisposition of the ex-soldier to endocarditis lenta is not due to infections of the heart prior to enlistment, since approximately four-fifths of the cases, even after the Ministry of Pensions had scrutinized their histories, failed to disclose any evidence of such infections. . . . The facts as to lesions and diseases contracted during service are, of course, open to the criticism that it is quite impossible to assess in figures the liability to injury of the various 'portals of entry' of infection; but it does seem reasonable to conclude that the reason why soldiers have become victims of endocardial infection does not lie in their liability to be invaded by micro-organisms through any particular tract. . . . There is, however, a very remarkable

* Delivered before the Royal College of Physicians, London, on March 25th.

fact, only imperfectly presented by the statements that 80 per cent. of the men were engaged in the more strenuous forms of military service, and that the average duration of service was 3.05 years, or nearly three-fourths of the whole length of the war. The fact is one which is not susceptible of arithmetical statement. It is this, that almost without exception the men whose military service was followed by the development of endocarditis lenta were men of fine physique and morale: men who joined the army early, served with all their might, and exerted themselves to the utmost limit of their physical power. . . . Looked at from the obverse side the same fact is equally striking. At the bases and elsewhere, both at home and overseas, there were large numbers of men of indifferent physique serving in the army; yet I have not so far encountered a single example of chronic endocardial infection amongst such men."

Carey Coombs does not miss the obvious point that excessive fatigue may predispose the body to infection, and thinks a biochemical link between fatigue and infection may be suggested by Walker Hall's work on the effect of dilute acids in accelerating blood cultures in nutrient broths.

Strain and fatigue overlap with arterio-sclerosis, with which in most cases hyperpiesia goes hand-in-hand. Upon these factors in the production of chronic endocardial disease I do not propose to dwell.

MARANTIC AND TERMINAL INFECTIONS.

I agree with Irving Simons, to whom we owe an excellent critical review of the whole subject of endocardial infections up to the year 1914, that the lesions occurring in the heart in cases of the so-called cachexias lack clinical significance, and are to be regarded rather as marantic thromboses than as true endocarditic manifestations. This statement refers to most of the positive *post-mortem* findings in cases of chronic nephritis, tuberculosis, cirrhosis of the liver, and carcinoma. They are to be distinguished, however, from cases of terminal septic endocarditis occurring in patients suffering from these same diseases, a class which, in my original survey, I included in the "latent" group. Although they usually are latent, it would be better to call them "terminal," since the word "latent" is more properly used for those cases of chronic infection which only come under observation as the result of one of the accidents incident to the disease, and especially embolic infarction.

I now pass on to consider that large and important, but heterogeneous, group of cases of endocarditis variously termed "ulcerative," "malignant," "infective," or "bacterial." The limits of this group are ill defined. At one end of a possible series into which they may be placed they fuse with the rheumatic group. Poynton and Paine, together with some other workers, describe a "malignant rheumatic endocarditis," considering that the rheumatic virus alone—in their judgement a specific streptococcus (the *Diplococcus rheumaticus*)—is responsible for such cases. At the other end of such a series are cases in which the endocardial lesions may be regarded as little more than intracardiac thromboses occurring in the course of a pyaemia.

A CONFUSING NOMENCLATURE.

The present nomenclature is avowedly very unsatisfactory. "Ulcerative" has the double objection that, even if we leave out of account for a moment Poynton and Paine's cases of malignant rheumatism, a process of ulceration occurs in severe forms of acute rheumatic endocarditis, as may be seen not infrequently in the *post-mortem* room, whereas by no means all cases of the bacterial group are associated with ulceration. Indeed, the absence of ulceration is an important feature in some of the more chronic cases. "Malignant" is an ugly and forbidding word to use, and however high may be the mortality in the fully fledged cases within this group some patients do certainly weather through. To both the words "infective" and "bacterial" the objection applies equally—that the rheumatic cases are presumably of this nature, despite our ignorance of the cause of the infection, and the syphilitic cases certainly are. The tendency during recent years to change the word "infective" for "bacterial" is curious, seeing that we have no knowledge of infections which are not bacterial. Beyond sharing the general dissatisfaction with any and all of these names, I am not anxious to introduce a new one. But I have a leaning towards a still older name than any of those now used, reactionary though it may sound to speak of

"septic" endocarditis. The word commits us to nothing in regard to pathogenesis, yet is expressive of the main differential features between this form of endocarditis and the rheumatic and syphilitic forms. Irving Simons regards the term "septic" as unfortunate, in that the lesions in many cases are not suppurative. But suppuration is by no means a necessary part either of acute or of chronic sepsis. Witness our use of the term in such conditions as "puerperal sepsis" and "focal sepsis"; in neither of these expressions does the word "sepsis" necessarily connote suppuration.

Unfortunately the confusion in words does not end here; confusion has of late years also invaded the terms by which we designate the type of disease as regards the intensity of the morbid processes involved and the duration of them. Although the words "acute" and "chronic," like a good many very common words, cannot be accurately defined, there is general consensus of ideas as to what they mean when applied to diseases. They are a convenient estimate of the two combined qualities already mentioned—intensity and duration. Now everybody seems agreed on the use of the word "acute" in relation to certain cases of bacterial infections of the type I am now discussing, but the cases that are not acute have been called "chronic," "subacute," and "slow" by different authors. As between "chronic" and "slow" there seems to be no difference. Schottmüller's account of the cases which he described under the name "endocarditis lenta," and which appeared in 1910, the year following the accounts contributed in this country by Osler and myself, makes it clear that he was dealing with the same kind of case which we called "chronic endocarditis." Individual cases of this chronic type had been described earlier than this, as by Bristowe, Lenhart, and others. In the same year Libman introduced the term "subacute bacterial endocarditis," and by a rapid series of papers, embodying observations and reflections of fundamental importance, has succeeded in establishing this term, for a time, as synonymous with both the earlier names.

Most of those who have considered the matter, and have contributed to our increasing knowledge of the subject, fail to distinguish between the cases originally designated "chronic" and Libman's subacute cases. And so it comes to pass that these two terms are, for the most part, used indiscriminately. Strangely enough, if there is any tendency to make a distinction between these two terms it is to use Libman's new term for a class of case which, on analysis, seems to be of even slower development and less intense symptomatology than the class of cases formerly called chronic. I shall refer to this point again, because of its important bearings upon pathogenesis.

ACUTE SEPTIC ENDOCARDITIS.

Acute septic endocarditis was recognized clearly by Wilks and others. Wilks introduced the excellent term "arterial pyaemia," and the words very aptly express the main features of the disease. Little or nothing has been added to our knowledge of this group of cases since Wilks's time. The heart and heart valves share in a general infection. The micro-organisms concerned are highly virulent in character—*S. aureus*, *Strep. pyogenes* (vel *haemolyticus*), the pneumococcus, and less often the gonococcus.

The onset of the disease is usually abrupt, the symptoms severe throughout, fever is high, rigors are common, and the course of the disease is rapid. A few doubtful recoveries occur. Death usually takes place in from ten days to a month, but there are fulminant cases which terminate in three or four days, and some, of less than the ordinary severity, which drag into the second month. The disease sometimes complicates osteomyelitis, erysipelas, pneumonia, puerperal sepsis, and less often some other acute local infections. I deal with it here thus briefly so as to give my groups of cases more clear definition.

Septic Endocarditis of the Right Side of the Heart.

Among the cases of acute septic endocarditis which I have observed of late was one in which the tricuspid valve was affected, and this valve alone. Since I regard the case as presenting the clinical picture to be expected in this somewhat rare condition, I will give a brief note of it.

A bar manager, aged 42 years, was admitted to St. Bartholomew's Hospital on the sixteenth day of an acute illness which was ushered in by shivering and headache. The man was seen by his doctor on the second day of his illness and put to bed, where he had been ever since. He became delirious on the third day and was transferred to a nursing home. About this time a patch of pleuritic friction was noted near the region of the right nipple, which disappeared in less than a week. There were no physical signs of pneumonia. The temperature chart, which was brought to the hospital with the patient, showed that there had been a fairly continued fever for four days after the record was begun, the temperature reaching 103° to 104° . It fell, but not by crisis, on the eighth day of the illness, and remained nearly normal for three days. It then rose sharply, with a rigor, reaching 104° to 105° . The delirium, which had subsided with the defervescence of the fever, returned. There was no headache. From the twelfth to the sixteenth days there were daily rigors, with profuse sweats.

On admission the patient was very ill, with low delirium, dry cough, and slight cyanosis. Examination of the chest yielded a soft systolic bruit near the apex, and a few rhonchi over both lungs. There was a leucocytosis of 10,800. A lumbar puncture gave normal fluid. A blood culture was sterile. Agglutination complement fixation test for tubercle bacilli were no choroidal tubercles seen. No organisms were found in the stools. The urine was sterile. The spleen was not palpable. No petechiae were present. Rigors continued almost daily, with high quotidian intermittent fever. On two separate occasions definite areas of crepitation, with soft pleuritic rub, were found, one in the right flank and one in the left axilla. There were no sputa. The frequency of the respirations was constantly raised. These, and the persistence of the apical systolic bruit, were the only physical signs elicited. Two further blood cultures were negative, but on the thirty-third day of the disease the blood yielded a growth of pneumococci. The patient, very ill at all times, died on the thirty-fifth day of his disease. At the post-mortem examination recent vegetations of the septic type were found on the tricuspid valve, and both lungs contained recent infarcts. There was about a pint of blood-stained serous fluid in the right pleural cavity. This fluid and the heart's blood both showed pneumococci in film preparations.

The chief diagnostic feature in a septic endocarditis of the right heart, whether tricuspid or pulmonary, is the association of the signs of endocarditis with multiple pulmonary infarction. The intensity, and the duration, of the disease process depend, as in left-sided cases, upon the virulence of the infecting microbe. The case just mentioned, being pneumococcal in nature, approximated to the acute forms of septic endocarditis. In a case which I included in my first series the micro-organism was a salivary type of streptococcus, and the infection was grafted upon a congenitally stenosed pulmonary orifice. The patient was a young adult, and her illness dated from the extraction of a septic tooth under local anaesthesia. In the first three months of her disease she had twenty-two attacks of pleurisy. Although she was known to be the subject of congenital heart disease of a mild type, the real nature of the disease was not recognized, and the repeated bouts of pleurisy, from which, however, she seemed to recover well, and a persistent pyrexia, led to her being sent to a tuberculosis sanatorium. Eventually her blood was cultivated and a streptococcus of the type *S. salivarius* was isolated. After an illness lasting for some nine months, and very thorough treatment, she recovered.

CASES INTERMEDIATE IN INTENSITY AND DURATION.

Between this group of acute cases and the group of chronic septic cases, which I shall take in more detail, there occur cases which I originally termed "subacute"—that is, cases in which the onset was less abrupt, the symptoms less dramatic, and the course less rapid. The causative micro-organisms are less virulent; the gonococcus and the pneumococcus are found in them at times, but more often the cocci approximate to those found in the chronic cases. Those cases termed by Lenhartz and by Poynton and Paine "malignant rheumatism" are of this class. So also, quite frequently, are those young adults who give a clear history of rheumatic fever in childhood or in the teens, and who present clear signs of residual valvular disease. The duration of these cases is from about three to six months. In view of the present confusion in the use of the term "subacute," I think it better to give no name to this group, but to be content to regard them as an intermediate class between the acute and the chronic cases. In any individual case we may, if we feel unhappy without a label, strain a point and call it chronic.

CHRONIC SEPTIC ENDOCARDITIS.

It is to the chronic cases, however, that much attention has been directed of late years, and deservedly so. The experience of the ex-soldier in this connexion is, given no other experience, very striking and very helpful in our understanding of endocardial diseases. But in civilian work also there is a growing recognition of the importance of these cases, and of the urgent necessity of detecting them as early in the course of the disease as possible. I shall deal with some of the main points of clinical interest as these have appealed to me, deferring matters of pathological importance until my next lecture.

Chronic septic endocarditis is a disease of adult life; its maximum incidence comes during the third and fourth decades. It is nearly twice as common in males as in females, a disproportion which exists quite independently of the war cases. It is a very insidious disease; it is not at present possible to estimate, except approximately, the date of its origin in the great majority of cases, nor, in those few cases in which we have good evidence of recovery, can we say when it ceased to be an active disease process. But allowing for these things, it is probable that the disease lasts, on an average, about six to nine months. Not a few cases reach twelve months, and there are reliable records of cases lasting two and two and a half years. Proofs are accumulating that there are recurring cases, also that spontaneous cures occur. Of these cases I shall say more later.

The earliest symptoms of the disease are undoubtedly of the toxic kind. Chills or sweats are perhaps amongst the earliest but an accidentally discovered pyrexia, frequently leads to observations that discover something seriously wrong in many of the cases. Pyrexia is almost always present at some time or other in the course of the disease. It has little or no recognizable features to guide us. It is rarely high. Apyrexial periods are not uncommon, even when the temperature is taken every four hours, an important point in the general observations. Rigors are quite unusual.

VARIATIONS IN THE PYREXIA.

Exacerbations in the pyrexia are often concomitant with embolic events, and especially with embolism in branches of the splenic artery; the attendant perisplenitis is probably the main source of the fever in this case. That the pyrexia frequently ranges higher with the occurrence of embolic infarction was pointed out by Douglas Powell in his Lumsden Lectures in 1899, when he showed temperature charts illustrative of this fact. But I do not know that attention has been drawn to the fact that the pyrexia not seldom falls to a lower level after these exacerbations and remains there for several days. This is not the result of decreased ability to react to the toxæmia, because the patients often feel fitter during this period of lower pyrexia following an exacerbation. It certainly looks as though the mechanism of embolic infarction results in some instances in the manufacture of antibodies to the infecting agent. It would be interesting to examine the patient's blood for these substances by complement fixation or by other means after such a process, and compare the titre with that obtained at other times. I have wondered if the process of embolism in this disease is not sometimes of service to the patient, as well as being, at other times, the direct cause of a tragic end. Provided the infecting microbe is not so pathogenic as to overthrow the local resistance altogether and lead to an abscess—which is rarely the case—and provided the embolus does not occur in a vital part like the brain—an all too common contingency—it is quite possible that the extraordinary slowness with which the disease sometimes progresses may in part be explained by such a view. I have been struck by the fact that in the two cases in which I have seen the largest spleens—in both the organ was visible on inspection of the abdomen, and its lower border lay well below the umbilicus—the general condition of the patient was well maintained for months together. In one of these cases the spleen had increased so greatly in size during a stay of five months in the winter in the open air at the South of France that on the patient's return I wondered if she had developed leukaemia. In the other case my opinion was asked because, though a diagnosis of septic endocarditis had been

made provisionally, the very large size of the spleen had actually thrown doubt upon it. In this latter case the effect of splenic infarction, as estimated by attacks of pain in the upper and left side of the belly, was seen in striking fashion in the temperature curve, as also was the subsequent improvement in the general symptoms. Remissions in the disease are often attributed to some special line of treatment which is being pursued, such as the use of a vaccine. Before such a conclusion can be accepted it is important to inquire if the remission be not possibly correlated to splenic infarction.

SOME IMPORTANT SYMPTOMS AND SIGNS.

Clubbing of the fingers has, since Cotton's observations published in 1922, become a valuable help in diagnosis. This observer, working in Lewis's clinic, found that of 63 out of 798 cases of structural heart disease in pensioners in whom this sign was present, 44 proved to be cases of chronic septic endocarditis, and of the remaining 19 cases 4 were regarded as doubtful instances of the same disease. This observation has found corroboration from many sources. Starling thinks that in the majority of cases the occurrence of clubbing indicates that the disease has been present for some time. It is clear that the association of this sign with acquired valvular disease must put us on our guard.

I referred in my original account of the disease to the frequency of *pains in or about the joints*. I do not think sufficient attention has been paid to these symptoms by subsequent writers. There is a point of great importance in connexion with the manner of their appearance, and that is their suddenness. A second important point is the difficulty that patients often have in locating them; and a third is the absence oftentimes of any recognizable effusion when the affected part is a joint, so that I have sometimes spoken of these pains as being arthralgic rather than arthritic. The situations of these pains are very numerous; the regions of the foot and ankle are the most common, then perhaps the hip and shoulder. But the wrist, the back, and the sacrum are not uncommon. The abrupt onset of the pain, and the fact that in not a few cases critical examination discovers a dusky red patch of tender skin in the neighbourhood of the pain in those cases in which the affected part is not a deep structure, makes it probable that the origin of the event is embolic. Many of these pains, even if there be associated swelling, are of quite short duration, passing off completely and leaving no residue, either subjective or objective. In the investigation of a doubtful case, if no history of these pains be given by the patient, inquiry should be made, because it not seldom happens that the event has been considered of no special significance owing to its transient character.

The *ephemeral cutaneous nodes* of French physicians—now generally called after Osler because of the detailed description given of them by our late gifted and lamented colleague—have been proved to possess all the pathognomonic value which he attributed to them. I know of no feature in a suspected case which possesses such dire significance. Again, owing to their fleeting nature, inquiry should be made for these lesions if they are not present when the patient is first seen. No doubt they, too, own an embolic source. The most common situation for them is the pulp of the finger or toe. They also occur on the thenar and hypothenar eminence. I have described analogous lesions as occurring occasionally in the bed of the nails, where a thin splash of red may be seen, accompanied by exquisite tenderness if pressure be made upon the affected part. These nodes arise suddenly, with sharp pain, as though the finger has been pricked; indeed, patients often examine the part carefully to make sure that some sharp object, like a thorn or a splinter, has not been the cause of the sensation. One patient, a typist, found that she could not use a particular finger for two or three days because of the tenderness caused by pressure on the keys of her instrument. A few hours after the onset of the pain an erythematous patch appears, pinkish at first, and later dusky red, with oftentimes a centre of white skin rather suggestive of an urticarial wheal. There is usually slight swelling of the discoloured skin. The redness disappears, and the tenderness also, in about one to three or four days.

The presence of *petechiae* in the skin is quite a different sign from that last described; though of much less diagnostic value it is still very important. As I have pointed out, a favourite and early situation for these lesions is about the neck and clavicles; other common situations are the chest, forearms, legs, and buttocks. Needless to say, two or three scattered petechiae may be very easily overlooked unless the possibility of their presence is specially borne in mind and the body is scoured for them in a good light. Like the nodes just referred to, these petechiae are short-lived; they tend to appear in small crops. We have no proof that they are embolic in origin.

There is general agreement that a *leucocytosis*, at least of any considerable degree, is not a feature in these chronic cases. Indeed, the type of count is very apt to be round about 9,000. In my second series of cases the actual figure averaged 9,300. But a leucopenia is quite common. This contrasts markedly with the leucocyte count in the acute cases, in the second series of which the figure averaged 22,000.

The degree of *anaemia* varies much. It may be so great as to raise the question of pernicious anaemia, especially when a marked leucopenia is present. But the proportionate reduction in haemoglobin seems to be invariably greater than the reduction in red cells. It is to be noted that some patients retain their blood, and especially their content of red cells, surprisingly well under treatment, especially if kept in the open air. I have seen an erythraemia in one well marked case, but the haemoglobin content was well below 100 per cent.

Pallor of the skin is a striking sign in the chronic cases, though if this be marked, and particularly if the curious tint of the complexion to which Libman has given the term "*café-au-lait*" be present, the case is generally of considerable standing. As in the case of the actual blood content, however, it is surprising how well some of these patients keep their complexion for a long time if treated in the open air.

EMBOLIC EVENTS.

Next to the evidence of endocarditis, consideration of which I take later, *embolism* is undoubtedly the most constant of all the signs of the disease. It was recorded in 142 of my second series of 162 cases. The vessels affected were, in the order of frequency, those of the spleen (108 cases), the kidneys (93 cases), the brain (26 cases), and the arteries of the limbs (13 cases). To these situations must be added the retina and the skin. Embolism, or one of its sequels, is not infrequently the event which brings the patient under observation, and in many instances of apparently mysterious signs and symptoms it is this process which offers a satisfactory clue to the problem. Be it remembered that the size of the detached fragment of material may vary from something microscopic to something so large as to obstruct a vessel of considerable size.

1. *The Spleen*.—This is the most commonly affected of the internal organs. The more chronic the case the more common is it to find the spleen enlarged during life; indeed, it is probably correct to say that in chronic cases a palpable spleen is an invariable finding. Early in the disease, and when the organ is as yet not palpable, pains in the upper left quadrant of the belly or hereabouts are highly suggestive. These pains, associated with fever, and perhaps referred to the flank, are sometimes mistaken for pleurisy; when friction is present, as it may be, the error is difficult to avoid. But pleurisy may actually be present in addition. I have only once seen a pleurisy with effusion (which was aspirated) complicate the splenic infarction. Although, as already mentioned, in some of the slow cases the size of the spleen may be very considerable, we must not conclude, from our knowledge of the great frequency of infarction in it, that this is the only factor in the enlargement. There is doubtless the general factor of toxæmia, and there is also the factor of anaemia. Unlike the spleen in acute septic endocarditis, the organ is generally quite firm, and the infected areas almost never suppurate; the nearest approach to this seen *post mortem* is some degree of grumous softening; even this is uncommon.

2. *The Kidney*.—If we consider in connexion with this

organ that the glomerular lesions, which are so characteristic a feature, are embolic in nature, as they probably are, then it is likely that the kidney is affected by the embolic process quite as often as the spleen. The frequency of embolism here must not, as has often been pointed out, be judged only by the appearance of a haematuria; in many cases the number of red blood cells passed in the urine is so small as to call for microscopical search, and this should be undertaken very frequently. I have pointed out that a small haematuria may be missed, but a brief albuminuria consequent upon it may be detected; intermittent albuminuria should, therefore, suggest renal infarction just as intermittent haematuria does. The process of renal infarction is generally, but not always, painless. In one case under observation the renal emboli were accompanied by severe lumbar pain, so much so that calculus and tuberculosis were both suspected. We owe especially to Gaskell and to Baehr our knowledge of the intimate changes in the kidney, only ascertainable by microscopical examination. These investigators described a form of glomerular change which they regard as peculiar, and to which Libman, in particular, has come to attach great significance. Indeed, according to the last-named observer, the discovery of the hyaline-like change in portions of the glomeruli which is the end-stage in the Gaskell-Baehr type of nephritis enables us to say with confidence that an associated sclerotic heart valve is the result of a "healed bacterial endocarditis." If this conclusion be borne out by other workers, and we may regard the lesion as almost a specific effect of septic endocarditis, its value in *post-mortem* interpretations will be very great.

3. *The Brain.*—Cerebral embolism is by far the most serious of all the common events of this nature. It not infrequently brings a latent case very rudely into prominence; it often determines the fatal ending, and not seldom at a stage in the disease when, on all other counts, a hopeful period of quiescence has arrived in regard to the toxic process. Experiences like these it is which lead the physician to speak with caution even in the face of definite improvement in the general state, including quite lengthy periods of apyrexia. Death in this disease may be accidental and mechanical as well as the natural termination of an intractable toxæmia. The most common clinical result of cerebral embolism is hemiplegia, with aphasia if the hemiplegia be right-sided. Monoplegias are much less common. The resultant cerebral shock is usually considerable, and the outlook, even immediately, is grave. I have twice seen a second hemiplegia on the other side, the interval between the two attacks being in one case only three days, in the other case twelve months. The sequence, originally described by Douglas Powell, of haemorrhage following the septic embolus, is common, as *post-mortem* experience shows, but acute cerebral softening, short of actual haemorrhage, is perhaps quite as common a finding. Irritative cerebral effects occur as well as paralytic, and these may sometimes be correlated *post mortem* with subarachnoid haemorrhages. I found ten such lesions recorded in 118 *post-mortem* examinations. In none of four cases in which choreiform movements were present was there, unfortunately, any opportunity for *post-mortem* examination.

4. *Plugging of arteries in the limbs* is probably more common than is thought. Unless the arteries be carefully examined a bout of pain and some swelling, say, in the wrist and hand, or in the foot, is sometimes considered to be arthritic in nature, when it is really the result of embolism in the radial or one of the branches of the posterior tibial artery. That the arterial pulse is not often obstructed for long, and rarely completely obstructed, adds to the deception, since coldness of the part beyond the partial block, still less gangrene, does not occur. We must suppose that the absence of these last-named effects is due to the friability, not to say softness, of the embolus, allowing of rapid disintegration, or channelling, or both. All this is in marked contrast with the results following embolism, if this takes place, in (non-septic) mitral stenosis, when gangrene is not at all uncommon. A common sequel to these septic emboli in vessels in the limbs is *aneurysm*, the development of which helps to explain, no doubt, the absence of serious nutritional changes in the part supplied by the affected vessel.

C

I have twice seen *mesenteric embolism*. In one case there was an attack of abdominal pain, followed in three days by a swelling about the size of a golf ball, and situate just to the right of the mesial line and a very little below the level of the navel. Despite the unusually discrete nature of the lump and its peculiar situation, the case would doubtless have been considered one of acute appendicitis had it not been that about the time of this occurrence the patient became suspect on the score of a possible septic endocarditis. A positive blood culture determined the diagnosis. In the other case a surgical colleague removed a small aneurysm from the right ulnar artery near its origin from the brachial. A routine digital examination of the rectum had discovered the presence of two small firm lumps, lying close together, and felt easily through the mucous membrane of the bowel. They were thought to be enlarged glands. A *post-mortem* examination later revealed the fact that these were healed aneurysms on the superior mesenteric artery. There was a third small aneurysm on the hepatic artery. Death had occurred from haemorrhage into the cerebellum, no doubt secondary to another embolism in this situation.

Aneurysm of the *ophthalmic artery* occurred in a case under observation by Foster Moore and myself.

RELATIVE IMMUNITY OF THE HEART.

The state of the heart in chronic septic endocarditis deserves a note. The salient feature, and one upon which there is general concurrence, is that it maintains its functional capacity in a very striking manner. Indeed, it may be said with truth that this is not a disease of the heart at all, but of the endocardium; hence my expression in my first lecture, "*Endocarditis vera*." This fact contrasts markedly with the state of things seen in a rheumatic endocarditis, where to a large extent the converse applies. Many of the patients in the disease now under consideration enjoy complete cardiac sufficiency for months after they fall victims to their infection. This is no doubt the reason why so many of them do not come under our notice until long after the initial stage of the process is past. Soldiers remain in the firing line, doctors continue their arduous profession, farmers proceed with quite heavy labour, until one or other of the accidents of the disease leads them to report themselves. Even then it is often difficult to persuade them to consider themselves ill. This retention of cardiac efficiency, combined with that buoyancy and optimism which I have called "*spes endocarditidis*," renders these patients oftentimes difficult to treat. A doctor, casually mentioning to his partner that he could not see the print on the extreme right side of his newspaper, submitted to a cursory examination; it was found that he had the cardiac signs of aortic incompetence and a retinal haemorrhage; on fuller examination a diagnosis of septic endocarditis was not difficult. He refused treatment and carried on his work. A month later he attended a difficult confinement, using forceps. He woke the next morning to find himself hemiplegic, became comatose a week later, and died.

It is generally agreed that such evidences of heart failure as auricular fibrillation do not occur in these cases—another testimony to the same fact. This relative absence of myocardial involvement tends to persist to the last in many of the cases, though there is considerable divergence in the figures given by different authors as to the frequency of terminal heart failure. This divergence probably depends upon the fact that when small numbers of cases are dealt with the type of case which bulks most largely in the series from which the figures are calculated determines the figures. Taking my two series together, I found death with cardiac failure to occur in from 40 to 50 per cent. But both series contained a good many examples of the old rheumatic type of case. Yet in the groups which chiefly include ex-soldiers death has been due to heart failure in much the same proportion as this. Cotton gives 47 per cent., and Starling gives 60 per cent., in their two series respectively.

Renal failure is admittedly the most frequent cause of death next to heart failure. After this, in probable order of frequency, come *cerebral causes* (and especially *conia* following embolus), *exhaustion* from the prolonged toxicity, and *pneumonia*.

THE SURGERY OF THE JEJUNUM.*

BY

JOSEPH ADAMS, M.S., F.R.C.S.,

SURGEON TO ST. THOMAS'S HOSPITAL.

To the anatomist the jejunum is the upper two-fifths of the small intestine; to the surgeon it is that portion which begins at the duodeno-jejunal flexure and does not descend into the pelvis.

Traumatic Lesions.

Although the jejunum is nowhere protected by any covering but muscle the incidence of small intestine rupture is about equal in both jejunum and ileum. It may be that the relative emptiness of the jejunum affords some immunity. If it is accepted that the three possible mechanisms—a crush, a tear, or a burst—are the factors responsible for intestinal rupture, I think we may take it that the last very rarely affects the jejunum. Undoubtedly fixed portions of the intestine are most susceptible to tearing. The commonest cause of intestinal rupture is a direct blow on the abdominal wall by some object which involves only a small area but will push its way on so that anterior and posterior walls temporarily come into contact. What happens to the bowel between them depends on its fixity and its state of distension. If the rupture occurs at, or close to, the beginning of the jejunum, I think it is right to infer that the lesion is a tear.

The clinical aspect of intestinal rupture has been very closely studied and no description of the physical signs is needed here, but an inspection of hospital statistics does reveal the fact that many cases are watched for hours after admission before operation is undertaken. The most important point to be considered is the nature of the accident. If the abdomen has been struck by the hoof of a horse, the pole of a cart, the dumb-iron of a motor car, this in itself may often be sufficient justification for abdominal exploration. The prognosis can only be hopeful where operation is for rupture of the intestine and not for perforative peritonitis. Marked rise in the pulse rate, recurrent vomiting, diminution of liver dullness, and abdominal rigidity are all late signs. Local hyperaesthesia should be a sign of value, but is often unreliable on account of bruising of the abdominal wall. If improvement does not take place within two hours of the patient being placed in a well warmed bed it is highly probable that internal visceral damage is present, and the abdomen should be explored.

The prognosis of rupture of the jejunum is governed chiefly by the state of emptiness or otherwise of the bowel, and the interval between operation and injury. The time of the last meal should therefore be ascertained. It is remarkable that in not a few cases a very slight fall on the flat abdomen has been responsible for rupture of the intestine. In most of these the accident has probably occurred after a full meal. These are examples of bursting of the gut owing to its sudden compression at two or more points. The method of suture should be such as will avoid serious narrowing of the bowel lumen, and in cases of multiple or extensive ruptures resection may be necessary.

Resection of Small Intestine.

As to the amount of small intestine which can be removed with safety, Bremer removed 17 ft. 9 in. for a strangulated femoral hernia in a woman aged 61, who made a good recovery and lived for two and a half years, ultimately dying of marasmus; the only obvious defect in her metabolism was a slight failure of fat absorption. The jejunum, therefore, is a portion of the bowel which can be dispensed with, and experimentally Flint found that 50 per cent. of the small bowel could be safely removed from dogs; they lived on indefinitely in good condition, and the early diarrhoea soon ceased. Compensatory hypertrophy of the remaining mucous membrane takes place, but there may be evidence that fats are not absorbed, and dietetic error may easily lead to enteritis and marasmus. Fractional resection is more readily tolerated, even up to 75 per cent. of the small intestine.

Removal in the human being of small bowel up to two-fifths of its length makes little difference to metabolism, but I have been unable to find any case on record where the portion removed consisted of the whole jejunum. Most of these resections involve ileum rather than jejunum, since the type of lesion calling for such drastic surgery is likely to be a gangrenous strangulated hernia.

The Jejunum as the Seat of Intestinal Obstruction.

The higher the obstruction the more urgent the symptoms of pain and vomiting. Jejunal obstruction, if unrelieved, rapidly ends fatally. This portion of the intestine may be implicated in any of the ordinary forms of obstruction, whether it be internal hernia, adhesions, intussusception, volvulus, or due to new growth. Naturally its relationship to the duodenal fossae makes it almost certain that an internal hernia in this region will involve the jejunum. Of the other causes of obstruction adhesions are probably the commonest. Intussusception is rarely met with in this part of the small intestine. That volvulus may occur apart from the presence of initial adhesions or abnormal mesenteric arrangements appears certain; irregular peristalsis must in such cases be responsible, and this may be caused by injudicious feeding or the misuse of aperients.

The question of first importance with regard to small intestine obstruction is why it is so often and so rapidly fatal. Much investigation has been carried on to elucidate this problem. It is generally admitted that death from acute obstruction is due to the absorption of toxic material developed within the obstructed bowel.

The source of these toxins and their chemical nature is still the subject of controversy. Whipple has maintained that the poison is a product of the mucosal wall, especially of the duodenum; but many workers have disputed this conclusion, and have found that bacteria and the results of bacterial activity are necessary to the fatal issue. Closed loops of bowel freed from bacteria are quite compatible with health. Protein substances are acted upon by bacteria in closed loops not rendered free from organisms, and of all the products proteoses appear to be the most toxic. Such toxins must be absorbed and reach the general circulation for a fatal result to follow, and a moot point is whether the mucous membrane of an experimentally obstructed loop can or cannot absorb these substances. Vomiting does not remove the toxin, and as more is produced its absorption is increased. If the bowel were unobstructed it would be hurried along and death avoided. In human obstruction the crucial question is the degree of absorption which takes place in the bowel above the obstruction. Wilkie concludes, and I think with reason, that paresis of the jejunum is a most important contributory factor in toxic absorption, and this may exist and persist even when obstruction is successfully relieved by operation. Evacuation of the bowel contents is one important factor in recovery, but restoration of peristalsis is also essential. The jejunum is designed for absorption, and it is probably right to speak of its area as the "poisonous proteose level" in obstruction.

On the clinical side the obstruction due to an impacted gall stone is particularly liable to lead to this latent toxæmia, and not infrequently the obstruction is very easily dealt with and yet the patient dies. Presumably fatal absorption takes place because of failure of peristalsis, and the disease would possess an even higher mortality if the impaction occurred in the jejunum rather than the ileum, where such a stone is more commonly arrested.

Ulcer of the Jejunum.

Any and every variety of ulcer has been found in the jejunum, but that which we are most accustomed to meet with is ulceration following gastro-jejunoscopy. This is an example of man-made disease. The question of greatest importance is whether peptic ulcer can occur in the jejunum apart from this short-circuiting operation, which allows gastric juice to come in contact with the jejunum before neutralization has occurred. The question has been admirably discussed by Richardson and Patterson Brown.

Even in 1924 Patterson Brown was able to collect only thirty-five cases for both jejunum and ileum.

* Abstract of Hunterian Lecture before the Royal College of Surgeons of England on February 3rd, 1926.

Ulceration following Gastro-jejunostomy.

This important sequel to an operation, which (to quote Mr. Sherren's recent Bradshaw Lecture) "has done as much, if not more, for the good of the human race than any surgical procedure," is a most unfortunate blemish on the surgery of the stomach, and I do not think any surgeon of experience can claim that his patients are immune from it. That it is an artefact of gastric surgery is supported by the very rareness of simple jejunal ulcer. That special precautions taken whilst doing the anastomosis have reduced its incidence goes further to prove that the surgeon is often responsible. The use of absorbable suture material appears to be the most essential of these precautions, and Sherren has advised against the use of a clamp on the jejunum, which is a luxury rather than a necessity for the surgeon; it may perhaps be responsible for damage to the jejunum wall and thus be a source of hidden danger.

It is usual to speak of gastro-jejunal (or anastomosis) ulcer, and jejunal ulcer proper; but there is no doubt that the anastomosis ulcer is the commoner, and Walton would have us believe that even when the ulcer is found in the jejunum it has always spread downwards from the anastomotic line. Sherren does not agree with this, and neither do I, for I have operated on a perforating ulcer of the jejunum several inches from the suture line and not connected with it by any fibrous tissue. Nine cases of this lesion have come under my immediate care, and of these six should be classed as gastro-jejunal, two as jejunal, and one presented a gastro-jejuno-colic fistula; in five the gastro-enterostomy was performed by myself, and this represents roughly an incidence of 2 per cent. I am in the habit of using clamps on both jejunum and stomach. Up to 1917 I used to employ silk suture material and also to remove some mucous membrane from the jejunum; this I believe now to be undesirable, and there is something to be said for a separate stitch for the mucosa.

A matter which appears to me of the greatest importance in technique is the treatment of the mucosa. Moynihan in 1914 advocated removal of an ellipse of the mucous membrane from both stomach and jejunum, and other writers have followed the same lines. The more recent textbooks on operative surgery urge economy of mucous membrane. The object is to secure an immediate and relatively large opening and avoid a mere slit, but I do not believe this can always be done without risk of delayed healing. Better some swelling of the margin of the wound, and temporary blockage of the anastomosis, than failure of mucosal healing and exposure to erosion by acid secretion. How many surgeons realize the importance of the conservation of every bit of mucous membrane it is difficult to know, but Sherren is quite clear on the point, and he does not remove any redundant mucous membrane. That of the jejunum always appears to be excessive, but nevertheless I believe it should never be excised. Exactly how long the process of final healing takes is, I think, unknown, but I should put it down at quite a month, and possibly two. For this reason a careful dietetic regime is rightly insisted upon for at least three months from the date of operation. Fibrous tissue is not proof against the attack of hydrochloric acid.

The two cases which I should classify as true jejunal ulcer in my practice have occurred in patients who started their unfortunate gastric career with a perforation of the duodenum. In both of them an anterior gastro-enterostomy was performed later. In one the perforation was in the afferent loop, and the anastomosis was drawn off into a tubular connexion between the stomach and the jejunum. The other was a recurrent jejunal perforation, and I cannot say positively that there was no inflammatory thickening along the line of the anastomosis. This perforation was in the distal limb of the jejunum, an inch and a half below the junction with the stomach.

The clinical aspect of gastro-jejunal ulcer is rather difficult. Not all patients upon whom gastro-enterostomy is performed for positive lesions are at once converted to the eupeptic state; some are, and their enthusiasm is very gratifying; some convalesce slowly but give a perfect end-result; others relapse. Sherren, I think, has been a little

too sweeping in asserting that a gastro-enterostomy patient who is perfectly happy for two years after the operation never gets trouble again, and does not run the risk of a gastro-jejunal ulcer. But the majority of such patients will admit to periods of discomfort shortly after operation; gradually their symptoms acquire the characteristics commonly associated with duodenal ulcer. Hunger pain is often a prominent feature. The only physical sign in peptic ulcer on purely clinical examination is tenderness on pressure; this in gastro-jejunal ulcer is to the left of the umbilicus and a little above it.

Carman gives the following points in connexion with the diagnosis of gastro-jejunal ulcer by means of x rays:

1. Retention from the six hour meal.
2. Pain on pressure in region of first loop of jejunum behind the anastomosis.
3. Impaired peristalsis.
4. Ampulla-like distension in the region of the anastomosis.
5. Distortion of the stoma and pain on pressure.
6. Narrowing of the efferent limb of the jejunum near the stoma.
7. Dilatation of the duodenum or afferent limb of jejunum.
8. A definite pocket retaining the barium is rarely seen.

Since No. 8 is the crucial sign in the x-ray diagnosis of any ulcer, it will be readily seen that a positive diagnosis by radiography is by no means easy. Certainly not all deformities of the jejunum after anastomosis point to ulcer, but if the clinical signs suggest it there is usually support for the diagnosis in the x-ray appearances.

The Value of Jejunostomy.

Jejunostomy is comparatively rarely done, but there are many conditions for which I believe it may be useful, and several where it is positively indicated. As a place for the reception of food the jejunum is quite satisfactory. Milk, eggs, and sugar poured in by a tube and funnel at four-hourly intervals will easily maintain nourishment. At first the quantity should not exceed six ounces, but in quite a short time the jejunum becomes accustomed to further distension and ten-ounce feeds can be given. It appears to make little difference whether the milk is pancreatized or not. Such jejunal feeding is quite well borne after the first few days, and most patients will cheerfully submit to a regime which permits neither fluid nor solid by the mouth provided they are thus rid of their pain. But the use of a jejunal fistula is not limited to the ingestion of food. Jejunal drainage is the keynote to the successful relief of intestinal toxæmia, which I have already discussed in dealing with high intestinal obstruction. As to technique, a modification of the Witzel gastrostomy, originally suggested by Moynihan, has much to recommend it. It is rapid, it can be done without risk of soiling the peritoneum, and the loop of the jejunum chosen needs very little anchoring to the parietal peritoneum.

The most obvious indication for jejunostomy is as a substitute for gastrostomy. In my experience it is just as efficient, and it is easier to perform without risk of leakage. It is therefore appropriate as a means of feeding in cases of carcinoma of the oesophagus where the stomach is small and immobile, as well as in cases of malignant disease of the stomach itself, unsuitable for excision or gastro-enterostomy.

In certain cases of chronic gastric ulcer there is a distinct field of usefulness for jejunostomy. It is the only method of continuous feeding whereby the stomach can be given absolute rest and the patient's nutrition maintained even while at work. For this reason it has been recommended for bleeding ulcers of the stomach and duodenum. I have found it most useful in inoperable ulcers. Moynihan has made use of this method of feeding, and for irremovable ulcer he has advised it combined with jejunostomy. The x-rays show that the stomach, which is watched by radiographic examination, and he records cures at the end of periods varying from six months to three and three-quarter years; during this time his patients have received neither solid nor fluid food by the mouth. The question arises as to the need for the gastro-enterostomy. Swallowed saliva and gastric secretion of psychological origin are likely to be the only contents that need to be diverted from the pylorus, unless hypersecretion occurs in

such cases apart from digestion. My own impression is that all these activities are so reduced that the stomach is actually put out of action, and the value of the gastro-enterostomy has a bearing on the deformity which may result from cicatrization rather than on the actual healing of the ulcer.

My experience confirms Moynihan's suggestion that ulcers not amenable to gastrectomy may nevertheless be treated by jejunostomy. Possibly medical treatment without artificial feeding could show similar results, but it seems a pity that physicians are apt to rely on clinical signs, and do not appear to submit their patients to routine x-ray examination, which alone affords conclusive evidence of cure so long as the abdominal wall stands in the way of inspection of the stomach itself. Even epigastric tenderness is unreliable at times, and it may disappear when the x rays still show a hold-up of the opaque meal.

Jejunostomy has a further use in connexion with gastric ulcer—namely, as a preliminary to gastrectomy. A poorly nourished patient, worn out with gastric pain, may be made into a "good surgical risk" by simple jejunal feeding, and the large operation, which in the first instance could not be tolerated, may be undertaken with every prospect of success.

Jejunostomy in Intestinal Obstruction.

In opening the discussion on acute intestinal obstruction at the meeting of the British Medical Association in Bath, Sir William Taylor¹ considered the treatment according to the stage of the illness in which the patient was first seen. The early stage of obstruction need not concern us unless it involves the jejunum directly. Full exploration is permissible, and it is only necessary to deal with the obstructing lesion laid bare to the surgeon's view. The second stage is characterized by distension of bowel. Here the obstruction should be relieved, but in addition Sir William advises a temporary jejunostomy; it may be needed only for twenty-four or forty-eight hours. In the third stage the patient's condition will not warrant abdominal exploration. Relief of distension, and that under local anaesthesia, is all he would permit; later the obstructing cause may be dealt with. With this teaching I fully agree, based as it is on the arguments I have already brought forward concerning proteose poisoning from the contents of the upper reaches of the intestinal canal. Operating on patients in the second stage I have often been disappointed in my effort to empty the small intestine, and at the same time unpleasantly conscious of the risk of infection of the peritoneum. If this process can be satisfactorily set going by a jejunostomy it is much quicker and safer. Intestinal lavage can also be instituted, for, in between the periods of drainage, glucose and sodium bicarbonate can be let into the bowel. Toxins may be evacuated and toxins may be diluted; both processes advantage the patient.

With regard to the suggested treatment of the third stage the grave condition of the patient demands that something be done, and jejunostomy can be performed quite well under local anaesthesia; thus one of the greatest risks of operating on such a patient can be avoided. The question which naturally arises is, Why make an opening in the jejunum? Victor Bonney is credited with being the first to insist on the importance of draining at this high level, and his argument is that it is the jejunum which is water-logged with toxic fluid, whereas the ileum contains much gas as well as fluid. I am not sure that this observation is universally true, but, nevertheless, in view of the higher toxicity of the bowel contents at this level, I believe the treatment is sound.

The value of intestinal drainage in true paralytic ileus was well shown in a paper by me in the *Annals of Surgery* in January, 1910. This concerned two cases following fracture of the ribs, and the cause of the paralysis, no doubt, was the irritation of the splanchnic nerves.

The first case ended fatally in spite of abdominal exploration, which revealed no obstructing lesion. The second was much relieved by intestinal puncture, and finally cured by tying a sutured catheter into distended small intestine. I have no doubt

now that this operation was in reality a jejunostomy, and its good effect probably lay in the fact that the opening was high up. Siphonage was used to drain the bowel, and peristalsis was re-established in twenty-four hours. In forty-eight hours the contour of the abdomen was normal and the patient quite comfortable. The faecal fistula continued to discharge for three weeks, but in the end it healed spontaneously.

In this paper I urged the value of ileostomy whatever the primary cause of paralysis, whether peritonitis was present or not. Now I should rather say jejunostomy.

Jejunostomy in Peritonitis.

If we transfer our attention to peritonitis we shall realize that there may be as much risk from intestinal toxic absorption as from peritoneal toxæmia, and in many cases it is difficult to be sure by which route the poisons reach the blood stream. Recent successes claimed for lymphaticostomy would rather point to intestinal absorption as the fatal factor. It is certainly true that fatal cases of peritonitis manifest both true obstruction and paralytic ileus. The former can be caused by bands of very recent formation, not necessarily fibrous, but the mere gluing together and angulation of coils of small intestine. Paralytic ileus means a spread of infection from the serous to the muscular coat of the bowel, or a splanchnic intoxication.

With regard to the closure of a jejunostomy, if this is done by the Witzel technique trouble rarely arises; if carried out in a more primitive fashion (and time and circumstances may sometimes demand this) it is well to bring the tube out through a portion of the omentum, so that this may plug the opening when the tube is withdrawn. A fistula may thus be avoided and the patient saved a further operation for its closure when the danger stage has passed.

THE EFFECT OF EXERCISE ON INSULIN ACTION IN DIABETES.*

BY

R. D. LAWRENCE, M.D.,

CHEMICAL PATHOLOGIST, KING'S COLLEGE HOSPITAL.

THE effect of exercise in reducing glycosuria and blood sugar in diabetes mellitus has been known for many years. Allen¹ and others clearly demonstrated its action, and until the advent of insulin nothing material was added to their work. It was shown that in all grades of diabetes exercise caused a fall in blood sugar. The effect was not only temporary, for, if the exercise was continued day after day, the patient's general strength and carbohydrate tolerance were improved. Indeed, some of Allen's patients were able to keep well and sugar-free only when they took regular exercise. Severe cases with little endogenous insulin did not benefit to the same extent as the milder ones.

Early in insulin days Dr. G. A. Harrison and I, working together, noticed that exercise had an effect in increasing the action of insulin in reducing blood sugar, and that on days when exercise was taken symptoms of hypoglycaemia were liable to occur on the usual balance of diet and insulin. As the strength and activity of patients have increased under insulin treatment, this has become still more obvious. The effect of exercise has to be considered to such an extent in arranging the proper balance of diet and insulin that, although I have already mentioned this briefly,² a more detailed record of the problem from the practical point of view seems necessary.

Hetzel³ has recently investigated the effect of exercise on blood sugar in patients taking insulin, but did not directly compare the effect of insulin with and without exercise. He did not investigate the effect of exercise when insulin is most active, from one to four hours after injection, nor of exercise prolonged over a considerable period, such as occurs in manual labour or in games and sports. Consequently he did not observe the marked effect of exercise in reducing blood sugar, which is so important a factor in the treatment of active diabetics.

* Working on diabetes with a grant from the Medical Research Council.

In this paper the clinical evidence of two cases which show this effect of exercise will first be recorded in some detail, and afterwards an experiment carried out on one of these patients.

CLINICAL EVIDENCE.

Both the cases recorded are young men who have been on insulin continuously for over one and two years respectively. They are skillful and careful dietitians, and keen observers of their own condition, following it carefully and almost daily by urine tests for sugar. They have been chosen for record for this reason, and because, though most patients show these changes to a lesser degree, the variation in the conditions of life of these two is such that the effects of exercise have been brought out to a marked degree.

CASE I.

This patient leads a sedentary city life during the week, but plays tennis or some other game regularly over the week-end. In the winter of 1924-25 during week-days he required 16 units of insulin to balance adequately the 20 grams of carbohydrate of his breakfast—that is, to keep his urine sugar-free and to reduce his blood sugar from the fasting level of about 0.16 to 0.01 per cent. or thereabouts. On Sunday mornings, when he played three or four sets of tennis, he found he could not take more than 10 units of insulin without developing symptoms of hypoglycaemia in the middle of the game; 8 units instead of 16 were really sufficient to keep him sugar-free when exercise was taken. The time of onset of hypoglycaemic symptoms (shakiness and palpitation) varied with the time and the vigour of the exercise. Insulin was taken at 8.30 a.m. and breakfast at 9 o'clock, and if he started to play at 10 o'clock hypoglycaemia never appeared before one and a half hours' exercise—about 11.30. If he commenced to play about 11.30 then symptoms often occurred three-quarters of an hour later, about 12.15 p.m., presumably because he then started to play at a time when insulin had already lowered the blood sugar considerably. Being interested in these phenomena, and not caring much about slight hypoglycaemia, from which he always speedily recovered by eating two lumps of sugar, sometimes without interrupting his tennis, although it became temporarily shaky like himself, he tried the effect of playing from 10 to 11 a.m. and then stopping before symptoms occurred. He found that even at complete rest symptoms usually occurred at 12.30 p.m. or soon after, presumably because exercise had burned up more sugar than usual, and as the insulin action proceeded it caused hypoglycaemia even when exercise had ceased.

However, if he took his usual dose of insulin in the morning and played tennis only in the afternoon, symptoms of hypoglycaemia never developed however strenuously he might play, presumably because by that time the activity of the insulin had worn off. But if after such exercise in the afternoon he took his usual evening dose of 12 units to balance the 20 grams of carbohydrate of his evening meal, not infrequently he got symptoms of hypoglycaemia three hours later. Occasionally after unusually strenuous exercise all day the balance of diet and insulin was upset even on Mondays, when the usual dose of insulin sometimes caused slight hypoglycaemia just before lunch time. Further observations were carried out on the effect of exercise on the patient's fasting blood sugar level. Usually this is about 0.16 per cent. It was raised above this to 0.22 per cent. by giving 30 instead of 20 grams of carbohydrate at the evening meal for several days running, during which time the patient was passing sugar in the urine most of the day. Four strenuous sets of tennis after supper was insufficient to cause hypoglycaemia at that high blood sugar level, but reduced the fasting blood sugar next day to 0.151 per cent.; on another morning after several days' exercise it fell to 0.121 per cent.

From the above observations we may conclude that exercise not only increases the power of actively circulating insulin to lower blood sugar, but actually burns up sugar and depletes the carbohydrate stores of the body. The fact that exercise in the afternoon occasionally upset the balance of the evening diet and insulin shows that exercise of itself increases the consumption of sugar even in a severe diabetic when the main action of insulin has worn off. The latter point was already well known, is not material to the main object of this article, and will be discussed in another paper with some other experiments which throw light on the exact site and mode of insulin action.

The same patient made some further observations on himself during a strenuous three weeks' holiday. True no blood sugar estimations were carried out during that period, but he made frequent urine tests for sugar with Benedict's solution, and as his leak point for sugar is about 0.19 per cent. and his hypoglycaemic level about 0.075 per cent., between the two his blood sugar level was sufficiently well known without blood sugar estimations. To appreciate the change that exercise made in his

carbohydrate tolerance I should state that his usual dose of insulin was at that time 28 units a day and his carbohydrate intake 45 grams, and that the addition of 10 and even 5 grams to this immediately caused hyperglycaemia and appreciable glycosuria.

To allow for the effect of the increased exercise during this holiday, instead of decreasing his carbohydrate intake he increased it from 45 to 80 to 100 grams a day. He took exercise, sometimes fairly strenuous, morning, afternoon, and evening. He was sugar-free all day on this largely increased diet, and even had occasional threatenings of hypoglycaemia, which he relieved with biscuits or lemonade. He increased in weight from 10 st. 3 lb. to 10 st. 11 lb., so that the absence of glycosuria was in no way due to a reduced caloric intake of protein and fat. He became noticeably fuller in the face and the bulk and firmness of his muscles was greatly increased. This is evidence that exercise enabled the same insulin to metabolize normally far more carbohydrate than was contained in his usual sedentary diet.

CASE II.

This patient shows the more gradual effect of exercise on insulin requirements. He is a gardener, who varies the amount of his work considerably from time to time. He has been on a diet of 60 grams of carbohydrate, 90 grams of protein, and 135 grams of fat for eighteen months—that is, 31 calories per kilogram of weight—and his weight has remained practically constant during this time. From October, 1924, to April, 1925, he remained on a constant insulin dosage of 10 units in the morning and 6 units in the evening. His blood sugars were always about 0.09 per cent. four hours after the morning dose of insulin and he was always sugar-free. In May he began to do more work and to play cricket in the evening, and very soon a reduction of insulin had to be made to prevent unpleasant symptoms of hypoglycaemia before his midday meal (blood sugar=0.075 per cent.) and occasionally in the evening. His insulin had to be gradually reduced in the beginning of July to 6 units a day—a very marked reduction. In the middle of July he stopped working and playing cricket; by the end of July his blood sugar was beginning to rise (0.187 per cent.), and by the end of August was 0.243 per cent., and sugar had reappeared in the urine. He was put back on 8 and 5 units a day, which kept him all right until he began to work again. This brought on quite marked hypoglycaemia and a blood sugar level of 0.057 per cent., so that the insulin was again reduced to 6 units once a day. He still keeps his diet constant, but has learnt to adjust his own insulin according to the amount of work he is doing.

Although it is a matter of conjecture, which I have not proved, I believe that the insulin requirements of these two cases could be interchanged by reversing their condition of life. If Case I adopted a life of manual labour, I feel sure that only one moderate dose of insulin would be required to keep his metabolism normal (unless his diet had to be increased to meet the increased exercise); while if Case II became sedentary in his habits he would require two moderately large doses a day, so great is the effect of exercise in aiding insulin to metabolize sugar normally.

AN INSULIN-EXERCISE EXPERIMENT ON A DIABETIC.

The results of an experiment on Case I are recorded in the accompanying table and figure. On one day the effect of exercise and insulin on his blood sugar was observed and a few days later the effect of insulin alone. Care was taken to make the conditions before the experiments as similar as possible. Before each experiment insulin was omitted for twenty hours and precisely uniform conditions of diet were observed. The early morning dose of insulin was omitted, breakfast and lunch taken as usual, and the patient allowed to have a moderately high blood sugar and to be in a thoroughly diabetic condition when the experiments were commenced at 2 p.m.—an hour and a quarter after lunch, which contained 7.5 grams of carbohydrate. The blood sugar level fasting in the morning was, on the two days, 0.161 and 0.160 per cent., and from the blood sugar level at the commencement of both experiments it is obvious that the carbohydrate metabolism (the blood sugar and presumably the glycogen stores) was as uniform as can be obtained in a severe diabetic. The experiments were not carried out entirely in the fasting condition, and perhaps one or two grams of the lunch carbohydrate were still being absorbed during the first hour of the experiment.

At 2 p.m. a dose of 10 units of insulin was given on both days, and on one day (A) strenuous exercise was carried out for the next two and a half hours with intermissions only for bleeding. The exercise consisted in riding a stationary bicycle against a considerable brake, in rowing

a machine boat against high compression, and in exercise on a sliding seat. Each form of exercise was indulged in vigorously in turn until the groups of muscles used would respond no more. It is a tribute to insulin that this violent exercise could be carried out without undue fatigue, for three years ago the mere ascent of stairs made the patient's legs ache with exhaustion.

4.30 p.m.		

The effect of 10 units of insulin on diabetic blood sugar. A, with exercise; B, no exercise.

* Symptoms of hypoglycaemia.

The figures give striking proof of the effect of exercise in increasing insulin action. The difference on the two days is far greater than I had anticipated, and it is of interest to record what happened after these experiments. After B the usual 8 units were taken before the evening meal (20 grams of carbohydrate), and nothing unusual occurred either that evening or the next day. Immediately after A, at 4.30 p.m. 20 grams of glucose were given to relieve the symptoms of hypoglycaemia, and no further exercise was taken. In spite of that, symptoms recurred at 6.15 p.m., and a further 10 grams of glucose were taken. No insulin was administered before the usual evening meal, and the usual insulin and breakfast were taken next morning. Hypoglycaemia occurred at 11.30 a.m. in spite of the extra 30 grams of glucose and the omission of one dose of insulin. This can only be explained by the effect of exercise in burning up and depleting the usual carbohydrate stores of the body and upsetting the usual balance of diet and insulin next day.

It may be of interest and some practical importance to note the long time in experiment B before insulin had any appreciable effect on the blood sugar. In some former experiments⁴ I found that even in large doses insulin never reduced the fasting blood sugar level more than 40 mg. per cent. in the first one and a half hours, but Murray Lyon⁵ found that it usually dropped about 100 mg. in the first two hours. It is therefore perfectly safe, and may be deemed advantageous, to give a severe diabetic with a raised fasting blood sugar (0.016 per cent.) his insulin one or even one and a half hours before a meal with a view to lowering his blood sugar before the carbohydrate of his meal raises it.

It is not proposed to discuss here the questions that arise regarding the relative effect of insulin in storing or burning sugar in the body—questions on which other exercise experiments to be reported later have thrown some light. In the meantime it seems clear that muscular activity greatly enhances the action of insulin.

CONCLUSIONS AND PRACTICAL APPLICATION.

I. The immediate effect of exercise in increasing the fall of blood sugar caused by insulin is very great. This occurs only during the maximum period of insulin activity—that is, from one to four hours after injection. Severe and prolonged exercise and half the usual dose of insulin may produce as great a fall of blood sugar as the usual dose without exercise.

II. Besides the immediate fall of blood sugar, exercise causes insulin to burn more carbohydrate than usual and to deplete the body stores of carbohydrate, as the above clinical cases and the aftermath of experiment A show. For this reason the dose of insulin succeeding exercise has

often an unusually powerful effect in producing hypoglycaemia.

III. If the diet is kept constant, an increase of exercise over days and weeks allows a reduction of insulin to be made. This is one of the reasons why the dose of insulin can often be reduced early in treatment when patients leave hospital and adopt a more active existence. If this reduction is not made symptoms of hypoglycaemia appear. When the added exercise is omitted the insulin must be raised again.

IV. It should be the object of all treatment to enable a diabetic to lead a normal and varied life, and to forget all about his disease except at meal times. Accordingly allowances must be made for the changing conditions that may arise in his life. Patients should and do easily learn to reduce their insulin before unaccustomed exercise or activity, or they must take vigorous exercise only at times when the effect of their injections has worn over. Even after exercise, when the usual carbohydrate stores have been partially depleted, it is usually advisable to reduce the next dose of insulin. If exercise is increased over days or weeks it is obviously more physiological to increase the diet instead of, or as well as, reducing the insulin. The increased calorific output must ultimately be balanced by an increased intake, otherwise weight and energy will be lost. A diet which supplies 30 calories per kilogram of body weight may be a sufficient "maintenance" diet for a sedentary life, but 40 calories may not be too much merely to maintain the requirements of a more active existence.

THE KASTLE-MEYER TEST FOR THE DETECTION OF BLOOD

CONSIDERED FROM THE MEDICO-LEGAL ASPECT.

BY

JOHN GLAISTER, JUN., M.B., CH.B.,

ASSISTANT TO THE PROFESSOR OF FORENSIC MEDICINE, UNIVERSITY OF GLASGOW.

SOME time ago my attention was directed to the Kastle-Meyer test for the detection of occult blood present in faeces. Its technique and rationale are described by R. Goiffon in the *Manuel de Coprologie Clinique*. He there states "that the test is an extremely delicate one, with the result that interpretable traces of blood are rendered definitely possible clinically, and, further, that by its use the causes of important errors yielded by certain other tests for blood are practically eliminated." After careful perusal of the article it was thought by the writer that the test might prove of considerable value in the laboratory examination of blood stains from the medico-legal viewpoint. The results obtained from experimental work with the tests are regarded as interesting and important to the medical jurist.

Reagents.—Two chemical solutions are required for the test, one being hydrogen peroxide of strength twenty volumes; the other is composed of a mixture of 2 grams of phenolphthalein, 20 grams of potassium hydrate, and distilled water in sufficient quantity to produce 100 c.cm. of the reagent. These three ingredients are boiled, and during the process 10 to 30 grams of powdered zinc are added. Boiling is continued until the solution becomes colourless, the colour disappearing usually after about ten minutes. The reagent when prepared in this manner will remain effective for long periods if a small quantity of the powdered zinc is left deposited at the foot of the reagent bottle to ensure reduction. The technique of the test consists in adding about 10 to 20 drops of the Kastle-Meyer reagent to the suspected blood-stained surface, thereafter adding a few drops of fresh hydrogen peroxide. If blood be present a deep permanganate colour develops almost immediately.

Rationale.—According to Goiffon the rationale of the test lies in the facts that the phenolphthalein in the reagent is

reduced into phthalein by the zinc and is regenerated by the oxygen liberated from the hydrogen peroxide by the haemoglobin present. The solution being alkaline in reaction, the indicator readily permits of the development of the reddish colour.

Method of Applying the Test.—I have found by experiment that the test can be carried out successfully either with a solution of the blood extracted from the stain, when placed in a test tube, or with the stain placed in a watch-glass and a few drops of distilled water or 0.83 per cent. saline applied to moisten it. In using the watch-glass method the stain need not be left in contact with the distilled water or saline for more than a few seconds, the reaction to the test being given almost immediately after the small quantity of diluent has been added. This is of importance in medico-legal work, as the usual tests—Day's or Schönbein's test and others—require soakage of the blood-stained material for some hours before the testing chemicals are added if reliable results are to be obtained. In adopting the watch-glass method it was found preferable to add a few drops of the reagent and only two drops of hydrogen peroxide, as when more of the peroxide was added the reaction seemed to be delayed, and was not infrequently masked by the development of a copious dense foam; further, excess of peroxide produced a milky hue in the fluid, and when the colour reaction did appear it was retained only for a short period, whereas if but two drops were added the colour reaction developed quickly and remained for several hours or longer. It appears from experiment that distilled water is a more satisfactory diluent than normal saline for the medico-legal application of the test, as a quicker and more intense colour reaction is produced.

Delicacy of the Test.—A positive reaction with the Kastle-Meyer test was obtained with human blood a year old extracted with saline from filter paper on which it had been dried, even when in a dilution of 1 in 212,000. A similar blood-stain diluted to 1 in 800,000 with distilled water yielded an immediate and positive reaction. It should be noted that although a positive result was obtained with these strengths of dilution and would be given in much higher dilutions, it was not considered necessary to conduct further tests, as the delicacy of the reaction was thought to have been fully established from a medico-legal aspect. As the result of noting carefully the colour reactions when using dilutions of blood from 1 in 10 upwards, it was found that the extent of the colour obtained on adding the reagents is quantitative for the blood present only within wide limits.

Experiments with the Test.

In an endeavour to exclude a fallacious positive reaction with certain substances in the absence of haemoglobin, ninety materials were tested at random with the Kastle-Meyer reagent, but in no instance was a true positive reaction exhibited. In most cases where chemical fluids were used the solution was about 20 per cent. in strength, which was regarded as being stronger than a dilution likely to be obtained from a stain composed of such chemicals.

List of the Substances Tested.

Rust, urine, perspiration, seminal fluid, leucorrhoeal discharge, albumin, saliva, human milk, cow's milk, soap solution, red ink, healthy faeces, colostrum, bile salt (sodium taurocholate), aniline dyes (namely, chlorazol fast red, aqueous fuchsin, neutral red, methyl red), pitch, rubber solution, wheat, starch, arrowroot, tapioca, barley, rice, rye, oats, sago, bean, maize, potato, manganese chloride, barium chloride, mercurous chloride, mercuric chloride, phenylhydrazine hydrochloride, aluminium chloride, lithium chloride, ferric chloride, ammonium chloride, ammonium phosphate, calcium chloride, calcium carbonate, magnesium chloride, magnesium sulphate, magnesium carbonate, magnesium oxide, ferrous sulphate, cobalt sulphate, calcium sulphate, magnesium sulphate, aniline oil, sodium bisulphate, sodium acetate, sodium nitrite, sodium nitrate, sodium citrate, ammonium sulphocyanide, ammonium iron alum, silver nitrate, lead nitrate, sulphuric acid, gallic acid, citric acid, pyrogallol, carboic acid, chromic acid, tannic acid, naphthylamine acetate, azobenzol, ortol (photographic developer), copper acetate, copper subacetate, copper sulphate, potassium bromide, potassium bromate, potassium cyanide, potassium ferrocyanide, potassium ferricyanide, potassium nitrate, potassium chromate, potassium iodide, potassium chloride, logwood, bromine, annatto hyssopica (colouring material for milk), calcium fluoride, calcium hydrate, and iodine.

In the case of iodine it was found that on adding the reagents necessary for the test a dark red coloration with

an orange tinge was produced. This colour, however, did not resemble the permanganate colour which the test produces when blood is present. A positive reaction when once seen is not readily confused with other reddish colorations. If a few drops of a solution of one part in three of sulphuric acid be first added to the iodine solution a brownish colour is produced on the addition of the Kastle-Meyer reagents in the absence of blood.

Tests were made with cochineal, using the Kastle-Meyer reagents, because it was thought that the initial colour of this substance might readily mask a positive reaction when blood was present. This surmise was substantiated. It was found, however, that if a solution of blood be added to one of cochineal the latter loses its red colour and becomes orange on the addition of the testing reagents, whereas if they are added to a solution of cochineal which does not contain blood its initial red colour is intensified. On the addition of testing reagents to cochineal containing blood to which a few drops of a solution of one part in three of sulphuric acid had been added, a pale yellowish-green cloudy appearance was exhibited, whereas when blood was absent a milky orange colour was produced. If the testing reagents be added to a solution of cochineal containing blood to which a few drops of one part in three alkaline solution have been added, a very faint clear straw colour is produced, whereas if blood be absent a milky orange colour is noted.

Certain substances contained in the foregoing list—for example, potassium ferrocyanide, sodium nitrite, sodium nitrate, and potassium iodide—occasionally yielded a very faint pink colour on the addition of the testing reagents when blood was absent. The coloration alluded to was so faint that it should never be confused with a positive reaction by anyone who had used the Kastle-Meyer test previously. Goiffon has stated that it is not necessary to note the late colour reactions, or the very faint colorations, on account of the delicacy of the test, with which statement I am in complete agreement. If blood be present the extent of the coloration is well marked. In order to make assurance doubly sure in these cases, if three drops of one part in three of sulphuric acid be added to the substance under test before adding the testing reagents, a pink or reddish colour will not appear in the absence of blood. It is evident that the likelihood of encountering any of the last mentioned chemicals in a blood-stain is very remote.

Tests conducted with lochia obtained at the sixth day of the puerperium and blood-stained pus yielded positive results. The age of the blood stain under examination does not apparently impede the reaction, as markedly positive results were obtained with the test on applying it to a blood stain fifteen years old, as well as to portions of bones some thirty years old. It would appear that heat insufficient in intensity to char or scorch when applied to a blood stain does not prevent a positive reaction being obtained, since it was found that blood stains upon cloth kept for a year and then submitted to a temperature of 160° C. for one and a half hours, and to higher temperatures for varying periods, readily produced a positive reaction when a few drops of distilled water were added and the reagents applied. It should be noted, however, that if the heat to which the stain is submitted is sufficiently great to produce charring a positive reaction will not be exhibited. Scorching vitiates the test to the extent of producing only a faintly positive reaction, not sufficiently marked to warrant it being termed positive from a medico-legal aspect. Blood-stained cloth kept for a year, then boiled for an hour in 200 c.cm. of distilled water, produced a positive result both with the stain and the water in which it had been boiled. Similar stains boiled with 1 gram of Castile soap powder yielded a positive reaction when the soapy solution was tested, although the stained cloth gave a negative result.

The amount of blood present in the solution apparently matters little so far as the production of a positive reaction is concerned, because the smallest speck of blood upon filter paper revealed a strong reaction. If the blood solution under test be heated before the reagents are added the colour reaction is expedited, being almost instantaneous, but the solution quickly becomes milky, more especially if

the stained cloth is present. If the solution be heated after the reagents have been added, a clear ruby-red colour is quickly given. It is a wise precaution to remove the stained cloth before adding the reagents if the material be dyed a deep reddish hue, lest the dye coming into solution impart a pinkish colour, simulating a positive reaction when blood is absent. Stains composed of pig, ox, and sheep blood were also tested, but no difference in reaction from that of human blood of the same age was revealed.

Conclusions.

From my experiments with the test applied medico-legally, it would appear that it is very delicate and reliable in the detection of haemoglobin. It is apparently a worthy substitute for Day's test, which possesses many fallacies, requires fresh reagents, frequently fails to act when only small quantities of blood are present, and in certain cases gives only a faintly positive reaction, creating doubt in the mind of the examiner whether such should be regarded as positive or negative. With the Kastle-Meyer test there are no "border-line" results. The reaction is well marked, is practically immediate, and time is economized in not having to await soakage of the stains before applying the test, if the watch-glass method is utilized. This becomes an important consideration when there are many productions to be examined. The age of the stain does not apparently affect the delicacy of the test. It must not be forgotten, however, that, having regard to the extreme delicacy of the test, the greatest care must be taken to ensure absolute cleanliness of all vessels used in the medico-legal examination of the stains, in order to exclude rigidly extraneous contamination of the vessels as the result of a previous examination. The apparatus should be boiled, the test tubes and watch-glasses carefully scrubbed with a suitable brush and thereafter wiped with gauze.

The results of the foregoing experiments indicate that the test is one of superior value for the detection medico-legally of haemoglobin. The test should be used in conjunction with the microscopic examination of stains for the detection of the presence of mammalian blood corpuscles, and the precipitin or serological test in determining the source of the blood, provided the examiner has by experience of the latter test acquired sufficient knowledge to determine in an accurate manner the results obtained.

MALDEVELOPMENT OF OESOPHAGUS.

BY

RAYMUND THERON, M.D.LOND., L.R.C.P., M.R.C.S.,
 HONORARY ASSISTANT MEDICAL OFFICER, MATERNITY HOME,
 BLOEMFONTEIN.

A MARRIED woman was under my care recently during her second pregnancy. The first child is a healthy boy, aged 3, and is said to have weighed 9½ lb. at birth. She was not a robust-looking woman, and suffered from a series of bad colds with a little bronchitis throughout the eighth month of pregnancy. Towards the end of December she developed hydramnios, so that it became almost impossible to make out the lie of the child. She complained a great deal of thirst. The urine contained no albumin or sugar.

At term labour started with the sudden rupture of membranes and escape of a large quantity of liquor amnii. On my arrival I found the cord in the vagina; the vertex presented and the cervix admitted only two fingers; labour pains were absent. Under anaesthesia I replaced the cord, which was pulsating rather slowly, put on a tight binder, and raised the foot of the bed. Pains came on a few hours later, and about six hours after rupture of the membranes a male child, weighing only 5½ lb., was born. There was a great deal of mucus in its mouth and it was rather blue, but soon recovered. Delivery of a normal placenta caused no trouble.

The next day I was told that the baby had vomited a lot of mucus and most of the water it had been given to drink.

Although it was rather a lean and undersized infant it cried vigorously, and at first there seemed to be nothing much wrong with it. The reports as to the nature of the vomiting were contradictory, but by the third day it was apparent that the child was not keeping much down. As yet it had passed nothing but meconium. I noticed that, after a drink of water, it seemed to choke and soon regurgitated, rather than vomited, all of the water, mixed with mucus. The abdomen was sunken a little, but was otherwise normal. No peristalsis was noticed and no tumour could be felt. A catheter failed to pass more than about 4½ inches from the mouth down the oesophagus. A diverticulum or an impervious oesophagus was therefore diagnosed, and it was realized that no operation was possible that would benefit such a puny infant.

The next day it was reported that some flatus had been passed, besides a little more meconium. X-ray examination showed that an opaque bougie passed down the oesophagus only as far as the level of the fourth dorsal vertebra, and that a barium feed filled up a little pyriform sac at the same level and did not get into the stomach. In the stomach there appeared to be a bubble of air.

It was therefore concluded that we had that type of malformation of the oesophagus which is clearly described by Professor Arthur Keith in his *Human Embryology and Morphology* (p. 250). He states that it is not uncommon. The paratracheal or upper part of the oesophagus, which is developed together with the trachea from the hinder part of the primitive pharynx, ends blindly, while the retrotracheal or lower part, which arises from the primitive alimentary canal, opens from the trachea and is covered by non-striated muscle. This, of course, explained the presence of air in the stomach and the passage of flatus.

The child lived six and a half days, gradually becoming weaker, passing fair quantities of urine, and crying only at long intervals for a feed. It suckled well and could swallow about two or three drachms easily, and sometimes kept it down nearly an hour. Invariably, however, the feed, mixed with mucus, was regurgitated, and occasionally nearly choked the child.

Post-mortem examination exactly confirmed the diagnosis. The oesophagus ended abruptly with a slight dilatation just above the level of the bifurcation of the trachea, having no connexion with the latter at that point. At the same level, in the middle line posteriorly, a narrow tube with a lumen of about 1 mm. opened from the trachea and gradually widened until it joined the cardiac end of the stomach. The stomach and duodenum were normal. The first six inches of the jejunum was collapsed, while the rest of the intestines were somewhat distended with air and contained a little meconium. The bases of both lungs were oedematous. No further abnormalities were discovered. The emaciation was great.

This malformation may, of course, be "not uncommon" as congenital abnormalities go, but luckily it is rarely met with in practice. It is interesting from several points of view.

First, the baby continued to pass a good deal of urine, although the urine was rather highly coloured. Probably, therefore, the pharynx and oesophagus were able to absorb some fluid, as no rectal salines were given.

Secondly, it is proved that a newborn infant, and a puny one at that, can exist for six and a half days on absolute starvation.

Thirdly, this case may have some bearing on the theories as to the purpose and fate of the liquor amnii. That the liquor amnii consists largely of foetal urine is, of course, no longer believed. It is generally supposed that the liquor is secreted by the amnion. That the foetus does swallow some of it is apparently admitted by all authorities, since lanugo hairs can often be demonstrated in the meconium. In this case there was a large excess of liquor amnii, well over a gallon being discharged, and the question arises whether the excess of liquor might not have been a result of the foetus being unable to swallow and absorb the liquor. It seems quite reasonable to believe that normally the foetus swallows liquor amnii, deriving fluid from it wherewith to dilute the waste products of its metabolism and excrete these by way of the placenta.

Although the mother's general condition was not very good during the last few months of pregnancy she remained fairly well nourished. Her condition, therefore, could have had little to do with the undersized child she produced. The placenta macroscopically presented no abnormalities. Again, excessive intrauterine pressure on the placenta came into play only during the last few weeks of pregnancy, so that that could not have had much to do with the small size and insufficient nourishment of the infant.

It seems likely, therefore, that normally the swallowing of liquor amnii is an essential part of the foetal metabolism—not, indeed, for the solids contained in this fluid, but merely to provide an internal fluid supply to the baby.

SUPPURATING GONOCOCCAL EPIDIDYMITIS.

REPORTS OF THREE CASES.

BY

P. C. P. INGRAM, M.B., B.S. LOND.,

HONORARY PHYSICIAN FOR DISEASES OF THE SKIN, AND MEDICAL OFFICER
IN CHARGE OF V.D. CLINICS, ROYAL GWENTY HOSPITAL,
NEWPORT, MON.

THESE three cases of suppurating gonococcal epididymitis are recorded on account of the rarity of the condition. They are taken from a total of 1,982 new cases seen in the past seven years. Many of the modern textbooks, such as Thompson's¹ and Luy's,² do not mention it as a complication; Reith Fraser³ states that in a purely gonococcal infection there is never suppuration. Harrison⁴ mentions it, but states, as is borne out by the experience in this clinic, that it very rarely results in abscess formation. It is, however, a possibility that should not be altogether forgotten.

CASE I.

A seaman, single, aged 25, first attended the clinic on July 17th, 1919. He had had a urethral discharge (in which gonococci were found) for about a fortnight, and a primary sore. He received the usual treatment for each condition, and went away to sea a few days later, where he kept up the irrigation. He returned in about a month, and attending at the syphilis sessions had no special treatment for the gonorrhoea, which gave him no trouble until September 25th, when he was found to have an acute epididymitis of the right side and a slight discharge containing gonococci. He was admitted to hospital, and an abscess in the epididymis burst during the night. A smear of the pus from this showed numerous gonococci and no other organisms. The abscess cavity was lightly scraped and sewn up; by October 14th it was quite healed, and there was no discharge. He went out of hospital, but did not attend the clinic again.

CASE II.

A club steward, married, aged 28, first attended on November 21st, 1924. He had had a urethral discharge for a month, which he was treating by syringing with Condy's fluid. Numerous gonococci were present in a slightly purulent discharge; the first urine was hazy, the second clear, and there was a non-tender thickening of the left epididymis. He was shown how to irrigate, and given a mixture of potassium iodide, but did not attend again until January 18th, 1925. He stated that he had kept up the irrigation for a few weeks, and then, as the discharge had ceased, gave it up; it had now appeared again. There was no discharge, but the first and second urines contained many threads and the left epididymis was enlarged and tender. He attended regularly, but on February 9th the swelling burst. He was admitted, and next day the opening was enlarged and lightly scraped. Scrapings were examined by the pathologist, who reported no evidence of tuberculosis in the sections, nor the presence of any of the ordinary pyogenic micrococci, but that some of the cells seemed to contain Gram-negative ovoid bodies strongly suggestive of the gonococcus. On February 25th he was seen by the tuberculosis physician and tested with tuberculin. The reaction was quite negative. The wound soon healed, and he went out of hospital, continuing to attend the clinic for vaccines, etc. On March 12th there was no discharge; the urine was clear, containing a few threads only, in which were no gonococci or other organisms, and only a few epithelial cells. He did not attend for his final test for cure.

CASE III.

A labourer, aged 24, single, first attended on July 17th, 1925. He had had a discharge for three days, following exposure eleven days earlier. Gonococci were present in the discharge; the first and second urines were hazy, with threads. He was shown how to irrigate and given a vaccine, but attended somewhat irregularly until August 17th, when a right epididymitis developed. He improved under treatment, but on September 10th gonococci were still present in the urine obtained after massage of the prostate. On September 28th the urine was clear, and there was some non-tender thickening of the epididymis only. On October 22nd he attended with a single small discharging sinus from the adherent lower pole of the epididymis. The cord was definitely thickened without beading; the prostate was not enlarged, nor were the vesicles thickened. A smear of the pus showed gonococci and no other organisms. He was admitted and the sinus scraped. It was soundly healed by November 17th. On November 23rd he was examined by the tuberculosis physician, who reported no signs in his chest and that a test reaction of tuberculin failed to elicit any reaction at all. On November 24th the urine was clear, and a specimen after prostatic massage showed no gonococci or pus cells. On December 28th there was a similar result after passage of an acorn bougie as well, there being only a very slight thickening of the epididymis.

As Kenneth Walker⁵ points out, it is by no means always an easy matter to distinguish between the various forms of epididymitis. It is, of course, important that a gonococcal epididymitis should not be labelled tuberculous, or vice versa. The history may be misleading, and it is known

that an attack of gonorrhoea may predispose to a tuberculous infection in the organ. In most textbooks the liability of the latter infection to break down is given as one of the points in its favour in making a differential diagnosis.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

AN UNUSUAL CASE OF CARBON MONOXIDE
POISONING.

A MAN and wife, aged respectively 49 and 63 years, were recently found dead in bed, the woman lying in a natural position and the man lying across the bed, face downwards. There were no marks of violence on the bodies and no evidence that anything of a poisonous nature had been taken; the woman had been under treatment for diabetes. On *post-mortem* examination death was found to be due to asphyxiation by carbon monoxide poisoning, there being a 50 per cent. saturation of the blood with the gas in each case. The organs of the man were quite healthy. The woman, who was the elder, had cirrhosis of the liver, degeneration of the pancreas, and enlarged heart and spleen.

Interest in the case lies in the fact that there was no closed or anthracite or coke stove in the room; no gas was laid on, and there were no gas pipes in the vicinity. There was a small open fire grate, and when the couple retired to bed for the night the fire was left to die out as was the usual custom. Coal only was burnt, and some unconsumed remains were found in the grate. Carbon monoxide must have been produced by the fire and escaped into the room in sufficient quantity to cause death. The room was of about 1,000 cubic feet capacity and the window and the door were shut.

Another point of interest in the case is that the man was employed in a large steel works as a gasman, and was thus exposed to gas. At midday on the day before he died he had complained that the place in which he was working was full of gas and that he did not feel well. However, he walked home from work that evening about 5 o'clock and did not complain of being unwell then or afterwards. The couple were last seen alive about 10 p.m. The question whether the man had not died from inhalation of gas in the works was raised by the solicitor representing the man's relations with a view to compensation. The coroner's verdict was that death was due to asphyxiation by carbon monoxide, the source of the gas being the fire in the room.

Fairfield, Llanelly.

J. A. HUNTER, L.R.C.P. Ed.

ACUTE HAEMORRHAGIC PANCREATITIS WITH
EPIGASTRIC HERNIA.

THE following case appears to me to be of sufficient medical interest to merit publication.

A married woman, aged 49, was admitted to the Blackburn Royal Infirmary at 5 a.m. on February 16th, 1926. She was taken ill fairly suddenly at 9 a.m. on February 15th with violent pain across the middle of the abdomen—below the umbilicus and in the flanks. She vomited twice a little later, but had a constant desire to "belch." She had no pain in the shoulders or back, and the bowels were moved on the evening before admission with an enema, which gave a fairly good result.

She gave a history of having been troubled with her heart and with oedema of feet, etc., for a few years. She had two children, aged respectively 17 and 13, and had had an epigastric hernia ever since her last child was born.

The patient was a very fat woman, and obviously dyspnoeic and cyanosed. She was very tender all over the abdomen, but the maximum tenderness was in the flanks and lower umbilical region. There was definite rigidity, but its degree was masked by fat. There was no marked hyperaesthesia. She had an

epigastric hernia, which was tender and rather tense. No abnormal signs were found in the chest, and the urine contained a trace of sugar. Her temperature was 100.4°, the pulse 144, and the respirations 36. She was obviously suffering from severe shock, and an operation was considered inadvisable. She died in the institution at 12.45 p.m. on the day of admission.

At the post-mortem examination the epigastric hernia was found to contain omental fat, which was a little congested in the neck of the sac. The liver was very much enlarged and very yellow, especially in its right lobe. The gall bladder contained no stones, but it was atrophied, and its walls were very much infiltrated with fat. There was a marked fat necrosis in the omentum, and especially at its attachment to the abdominal wall and in the mesocolon. There was only a little fat necrosis in the mesentery, and the pancreas was very much discoloured with haemorrhage. The stomach was dilated.

Microscopical examination of the pancreas showed areas of free blood in the pancreatic substance. The spaces between the liver cells were very much infiltrated with fat, and the cells seemed to be few and far between. This infiltration was most marked around the area of the central vein. The kidney showed considerable cloudy swelling.

My thanks are due to Dr. W. Briggs, honorary surgeon at the Blackburn and East Lancashire Royal Infirmary, for permission to publish this case, and to Dr. F. S. Adams, honorary pathologist, for the report on the microscopical examination.

D. S. FAIRWEATHER, M.A., M.B., Ch.B.Ed.,
Senior House-Surgeon, Blackburn and East Lancashire
Royal Infirmary.

Reports of Societies.

TYPHOID FEVER IN NORTHERN IRELAND.

At a meeting of the Section of Epidemiology and State Medicine of the Royal Society of Medicine on March 26th, Dr. E. W. GOODALL in the chair, Professor W. J. WILSON read a paper entitled "Typhoid fever in Northern Ireland."

Professor Wilson first called attention to the great reduction of mortality from typhoid fever which had occurred, not only in the United Kingdom, but in most European countries. In 1875 the rate of mortality from typhoid fever in Ireland was lower than in England and Wales—1.6 per 10,000, as compared with 3.7. Between 1875 and 1886 the rate declined in England and Wales, but was almost stationary in Ireland; the rates in 1886 were 1.8 in England and 1.6 in Ireland per 10,000. Little change occurred in the next ten years, but since 1900 there had been a considerable decline, greater in England than in Ireland; the rates of 1924 were 0.13 for England and Wales, 0.31 for Ireland. Professor Wilson pointed out that in Ireland the rural population was relatively much more numerous than in England, and that the development of the creamery system, together with imperfect public health control, had been responsible for several outbreaks in rural areas. Passing to the special problems of Belfast, Professor Wilson presented statistical data illustrating the great decline of typhoid fever in that city. The mortality rate was 7 per 10,000 in 1872-75 and as high as 9.7 in 1896-1900; since 1910 it had never reached 1, and in 1924 was 0.07. Professor Wilson referred to the late Dr. L. W. Darra Mair's report incriminating shell-fish, and, while expressing his admiration of that report and his belief that much typhoid in Belfast had been due to the consumption of contaminated cockles and mussels, did not think that the great decrease of recent years could be attributed wholly to a change of habit in the use of shell-fish. He attached much importance to the abolition of privies, the substitution of ashbins for ashpits, improved scavenging, abatement of nuisances, decrease of stables and byres with their concomitant flies, more effective sanitary administration, the higher standard of living and education, and the growth of a sanitary conscience. Professor Wilson also thought that the work of Greenwood and Topley, dealing with the effect of constant additions of susceptibles to an infected population, had a bearing on the Belfast experience, and noted that the highest mortality prevailed during the periods of most rapid

expansion, when the increase of population was due, not merely to excess of births over deaths, but also to immigration. Professor Wilson concluded his paper with an account of a series of outbreaks which had been fully studied.

The paper was discussed by Sir WILLIAM HAMER, Sir GEORGE BUCHANAN, Dr. MAJOR GREENWOOD, Dr. S. MONCKTON COPEMAN, Dr. G. C. TROTTER, Dr. J. A. ARKWRIGHT, Fleet Surgeon W. E. HOME, and Dr. E. W. GOODALL.

TUBERCULOUS SALPINGITIS.

At a meeting of the Section of Obstetrics of the Royal Academy of Medicine in Ireland, held on March 12th, with the President, Dr. D. G. MADILL, in the chair, Dr. BETHEL SOLOMONS and Sir JOHN LUMSDEN contributed a joint communication on an unusual case of pyrexia.

A woman, aged 22, complained of general debility with pyrexia; there had been a previous attack resembling influenza from which she had recovered. Her symptoms suggested enteric fever, but tests for typhoid, and paratyphoid A and B, were negative. For six weeks there was some rise of temperature, the lowest record being 98.8° F., the highest 102.8° F. As no other definite cause of the pyrexia could be established Dr. Solomons examined her recto-abdominally, and finding some degree of fullness in each lateral fornix he advised a vagino-abdominal examination under anaesthesia, when a diagnosis of tuberculous salpingitis was made. The blood examination showed: Leucocytes 38,000 per cubic millimetre; differential count—polymorphonuclears 53 per cent., lymphocytes 33 per cent., eosinophiles 7 per cent., transitionals 7 per cent. When the abdomen was opened the tubes were found to be slightly thickened and larger than normal, with closed fibrinated ends; tubercles were not present. The tubes were removed in their entirety; the ovaries were bound up with them, but it was possible to leave a small portion of the left ovary. After sixteen days the pyrexia subsided and the temperature remained normal. The microscopic evidence made the diagnosis evident, the submucosa being packed with giant cells. Two months later the patient again became ill, and Dr. F. C. Purser diagnosed encephalitis lethargica; she had, in addition, an attack of diphtheria.

Sir JOHN LUMSDEN said that when he first saw the patient, at the beginning of June, she gave a history of having been ill for some weeks and of having had an attack about a month previously of what would appear to have been gastric influenza, though it had been diagnosed as food poisoning. Her pulse was 100, her tongue was furred, and the apex beat was displaced outwards; he thought that possibly some myocarditis was present. The patient went away, but a few days later was admitted to hospital. Her tongue was still furred, she was febrile, rather constipated, and hard to feed. Blood culture and Widal test were both negative. There were at that time no symptoms whatsoever of encephalitis lethargica. He, however, suspected that there was some tuberculous focus, although there was absolutely nothing to be made out in the lungs. The epigastrium was tender, and nausea occurred after food, which made him think that there was something wrong in the abdomen. Dr. Abrahamson then saw the case with him, and they concluded that it was a case of tuberculous peritonitis. Dr. Solomons saw her, and operated; after the operation she remained febrile for about fourteen days. During convalescence she became rather emotional, but improved enough to be sent to the country. Some time later Dr. Purser diagnosed encephalitis lethargica. It was, of course, just possible that the girl had encephalitis lethargica all through, but he did not think it probable. She then developed diphtheria, and died.

Dr. L. CASSIDY said that if tuberculous salpingitis was to be taken as a reason for the state in which the tubes were found it seemed rather an extraordinary procedure to mutilate an unmarried girl on evidence which seemed to him inadequate. Even the microscopical description of the tubes did not seem sufficient to account for the clinical symptoms in the case described by Dr. Solomons and Sir John Lumsden. He would have thought that the condition was either tuberculous meningitis or encephalitis lethargica. He felt that in cases of this kind the wisdom of employing either radium or x rays should always be considered. During the last few years he had seen about thirty such cases, and with the exception of two had seen good results

follow treatment by radium or x rays. He thought that the symptoms in this case pointed to tuberculosis, possibly in the upper abdomen, but not to a condition which would justify removal of the tubes.

Dr. L. ARRAHAMSON said that certainly when he had seen her there had been no sign of either tuberculous meningitis or encephalitis lethargica, and he did not think that when Dr. Purser saw her she had tuberculous meningitis either, as the cerebro-spinal fluid was not under tension when she was seen by him. Encephalitis lethargica was sometimes hard to diagnose, but when this patient was seen by Dr. Purser the symptoms were apparently so typical that the diagnosis was obvious. When the speaker had seen her she was suffering from pyrexia and vague abdominal pain. No evidence of tuberculosis could be found either in the chest or in the abdomen. When the contents of the tubes were examined for tubercle bacilli the result was negative, but when sections were made the bacilli were found. No naked-eye tubercles could be seen, but microscopically they were easily visible. He thought that removal of the tubes in this case was absolutely justified, and that the result was satisfactory; he believed that but for the development of encephalitis lethargica the patient would have lived. She had died from an intercurrent disease which had nothing to do with the original complaint. The result of x-ray treatment in these cases was the arresting of the internal secretion of the ovaries, whereas in this case, after operation, a little ovary had been left.

Dr. GIBSON FITZGIBSON said that the question, "Should active tuberculous tubes be removed or not?" was much discussed, but when he came across cases in which there was evidence of advancing disease he always took away the tubes. If the tubes were not removed the patient was left with disease; and if the tubes were removed the patient was no more sterile than she had been before removal, since if the tubes were tuberculous they were functionally useless. He had recently seen a patient who had been married for five years, but was sterile; he removed the tubes, as he felt sure they were tuberculous and functionally useless. The pathologist reported that the tubes were destroyed by tuberculosis.

Dr. R. J. ROWLETTE drew attention to the very high blood count in this case, which at the time the count was taken was apparently one of tuberculosis. He thought this was possibly evidence of an extreme degree of purely tuberculous toxæmia. Nowadays pyrexia was regarded as a symptom, not of tuberculous toxæmia, but of septic toxæmia; but in this case it was proved to be a symptom of tuberculous toxæmia. A curious feature of the case was that diphtheria occurred when encephalitis lethargica was also present. He thought it possible that tuberculin might have done the girl good, but it was necessary to open the abdomen to see what disease was present, and when the tubes were found to be tuberculous he thought it would have been very risky to leave the tubes and to give the patient tuberculin.

Dr. J. S. QUIN asked if erosion of the cervix was present or if there was any leucorrhœa. He referred to a case of pyrexia in which no tuberculous focus could be found at all, but in which, a few days before death, tuberculosis of the mediastinum set in.

Dr. G. W. TRENDALD referred to a patient who had been admitted to hospital said to be suffering from eclampsia. A lumbar puncture was performed, but the patient died five minutes afterwards. At the necropsy every gland was found to be a mass of tuberculosis. In the case described by Dr. Solomons, assuming that the patient had tuberculosis, encephalitis lethargica, and diphtheria, was it right to assume that the tuberculosis of the tubes was sufficient to cause the very definite symptoms from which she had suffered for a long period of time? Was it not likely that there was some focus of tuberculous infection elsewhere in the body?

Dr. BENJAMIN SOLOMONS said that the diagnosis of tuberculous salpingitis was obtained (1) by a process of exclusion of other diseases, (2) by bimanual examination, and (3) by the appearance of the tubes taken in conjunction with the history of the case. He disagreed entirely with Dr. Cassidy's remarks on treatment. Dr. Solomons had had a

very large experience of tuberculosis of the tubes; he had tried palliative salpingostomy in cases of sterility in these cases, and, as stated in previous communications, the results had been bad: either there was no cure of the sterility or there was recurrence of disease. He therefore strongly recommended complete salpingectomy for tuberculosis of the tubes. In this way the disease was removed, while the chance of pregnancy before removal was nil. There was no need to extirpate the uterus, for if infected the infection cleared up after salpingectomy. Treatment by radium and x rays was useful in general abdominal tuberculosis. There was no erosion of the cervix, nor was there leucorrhœa. So far as could be felt there was no tuberculous disease higher up in the abdomen. He was convinced that this was a case of tuberculosis of the tubes causing pyrexia and cured by operation.

GYNAECOLOGICAL SYMPTOMS.

At a meeting of the Edinburgh Obstetrical Society held on March 10th, with the President, Dr. R. W. JOHNSTONE, in the chair, a communication was given by Professor CARLTON OLDFIELD (Leeds) on symptoms without signs. This title was taken because there was no more common case than the patient who complained of various symptoms but in whom no physical signs could be detected. Out of 1,200 patients examined by Professor Oldfield only 434 (36 per cent.) showed any gross disease, and this he deemed to be due to the majority of the cases being functional. The usual symptoms in such functional cases were headache, backache, weariness, sleeplessness, and frequency, precipitancy, or incontinence of urine. For such conditions curettage was unnecessary and harmful, and likewise were operations such as ventrosuspension, cervical repair, appendicectomy, etc. The main symptoms were then taken seriatim, and backache was first discussed. This was found in 67 per cent. of Professor Oldfield's cases, but in only 34 per cent. of these was any organic disease present. Retroflexion was only present in a few more cases than anteversion, confirming the opinion that retroflexion, though often accompanying backache, was not the cause of it. Cervicitis, with or without laceration, and endometritis were not noted as being in any way definitely associated with backache, though as all these complaints were common they were bound to occur together in many cases. Backache, therefore, was usually a functional complaint. Incontinence of urine was then discussed, the incontinence being of the active kind and not passive, as in a vesico-vaginal fistula, etc. Of Professor Oldfield's cases 12.8 per cent. had incontinence, and yet 29 per cent. had urethrocele; among the cases of incontinence 28 per cent. had urethrocele and 28 per cent. prolapse. Prolapse was present in more cases with incontinence of urine than without, and therefore was probably a causal factor, though only 7 per cent. had cystocele; but urethrocele, on the other hand, occurred more frequently in cases without incontinence. Incontinence, however, was, in Professor Oldfield's opinion, purely functional, and this was proved to his satisfaction by the fact that application under anaesthesia of the electro-cautery cured nearly every case, which would have been impossible were it due to pathological or anatomical reasons, as was generally supposed. Many cases were quoted to support his contention. With regard to retroversion of the uterus, the statistics of Dr. MacGregor Young were quoted, in which 1,000 puerperal uteri were examined on the twelfth day after labour, and retroversion was found in 50 cases, but six months later only 2 were found to be still retroverted. Pessaries might relieve symptoms sometimes, but it was probable that in such cases prolapse was present. Professor Oldfield advised the discarding of the words "retroflexion" and "retroversion," and then pessaries would cease to be used or operations to be done in such cases. Many women were made unhappy by being told that their womb was twisted. In conclusion Professor Oldfield touched on the pernicious vomiting of pregnancy, which he considered always to be functional, and advised treatment by suggestion and feeding. In his experience such treatment had always been successful.

Dr. WILLIAM FORDYCE gave a short note on a case of ectopic gestation with unusual clinical features.

The patient, a multipara of 36 years, was admitted into his ward with the history of severe vaginal haemorrhage following what was supposed to have been an incomplete abortion, as she had three weeks previously passed a lump per vaginam as big as her closed fist. This was corroborated by her medical attendant. When examined under chloroform after her admission the os was found to be patulous, but nothing was found inside the uterus, the discharge being, however, somewhat foul-smelling. The patient progressed satisfactorily for a week, there being no further discharge and the temperature normal. She then began to complain of colicky pain in the right hypochondrium, and she became slightly jaundiced. Cholecystitis was diagnosed and she had a laparotomy performed two weeks after her admission to hospital. The abdomen was found to be full of bright red blood, and a foetus was found later amongst the clots. In all probability the sac had been ruptured by bimanual palpation immediately before operation.

In reviewing the case Dr. Fordyce thought that it must be classed as a "combined" gestation—both intra- and extra-uterine—for though on examination the patient was very stout, there was nothing like an ectopic gestation to be palpated, and yet before her operation a swelling could be felt distinctly. The pain and tenderness in the right hypochondrium was very difficult to explain.

Dr. F. J. BROWNE read a paper entitled "An experimental investigation into the etiology of accidental haemorrhage and placental infarction," which will be published in full in an early issue.

RADIOLOGY IN URINARY SURGERY.

THE ninth Silvanus Thompson Memorial Lecture, under the auspices of the Röntgen Society (of which Silvanus Thompson was the first president), was delivered on March 30th by Sir JOHN THOMSON-WALKER, who took as his subject radiology in urinary surgery. The President of the society, Dr. F. W. ASTON, F.R.S., was in the chair.

Sir John Thomson-Walker dealt in the first place, somewhat briefly, with the use of x rays in the diagnosis of conditions in the kidney and ureter, and showed a number of radiographs indicating normal and abnormal appearances. He gave it as his experience that in not more than 5 per cent. of cases would x rays fail to demonstrate a urinary calculus. The exceptions were cases in which stones did not throw shadows traceable even on the best plate or film, either because the stones were composed of pure uric acid or were hidden behind the wing of the sacrum or the pubic bone. He also spoke of the early diagnosis of dilatation of the kidney by pyelography.

Coming to the question of treatment, he said that malignant disease of the kidney did not appear to be a very promising field for x rays, though there were cases in which the patient was unwilling or unable to obtain skilled advice in the early stages of renal growth, and here the surgeon might be glad to avail himself of the help which x -ray treatment could afford. The only two cases of renal growth in which he had seen striking results follow radiotherapy were advanced cases with secondary deposits; in neither was a cure obtained, but the growth in both was greatly reduced and held under control for a considerable period of time. With regard to growths in the bladder, treatment by operation was very successful, and with better means of diagnosis bade fair to be still more so. The lecturer exhibited a table showing his own results in this condition. In simple papilloma he had employed transurethral electrocoagulation in 119 cases; there was no mortality, and there had been no recurrence in 74.4 per cent., the period which had elapsed since treatment varying from one to eleven years. Operation (excision) had been done in 142 cases, and the mortality was 3.49 per cent., and there was no recurrence in 65.74 per cent. In 126 cases of malignant growth in which resection of the bladder wall was done, the mortality was 6.34 per cent., and there was no recurrence in 66.3 per cent. On the whole, he thought that treatment by operation was satisfactory, but there were cases where diathermy or operation failed owing to the persistence or recurrence of the growth or in which these measures were unsuitable owing to the advanced state of the growth, the septic or contracted state of the bladder, a diseased condition of the kidney, or the feeble general state of the patient. Such cases were to the last degree un-

promising as subjects for radiotherapy, and the failure of x rays to cure them or to bring about any appreciable improvement could not be regarded as a reproach. Could radiotherapy be used to reduce the size of the bladder growth so as to bring it within the range of operation? In 491 cases of bladder growth under his care 118 were unsuitable for radical operation, in the majority of cases because of the extent of the growth. In view of the successful results obtained by radiation elsewhere in the body there seemed to be some prospect of success here also, but his experience in a few cases did not encourage him to hope that surgeons would obtain assistance in bladder-growth operations from preparatory treatment by radiation—rather the reverse. His experience of the post-operative treatment of growths of the bladder either by the gamma rays of radium or by hard x rays also was not encouraging. He had found a mild urinary infection converted into a severe cystitis, and in other cases delayed healing of the wound or tendency of the wound to break down after such post-operative radiation. His opinion was, therefore, that radiation in the immediate post-operative stage was not a suitable method for use in bladder growths. With regard to growths in the bladder which were unsuitable for operation or which had recurred after operation, the result with hard x rays had been sufficiently good to encourage a more extended trial. The only objection to radiation in bladder growths of this kind was the local reaction, and this should not stand in the way if good was done.

Sir John Thomson-Walker next described the value of x -ray treatment in malignant growths of the prostate, where the common form of malignancy was scirrhous carcinoma. Radical treatment of such growths was a very severe operation, and radiology had here a promising field in competition with surgery. The number of cases of carcinoma of the prostate under his care which had been treated with hard x rays was 48; the treatment had been carried out by twelve radiologists, seven of whom were in London, and one case was treated at Erlangen. A general reaction was noted in 18 of these cases, and was severe in 7. Local reaction was invariably present, though it differed considerably in cases which otherwise appeared similar. Of the 48 cases treated by radiotherapy, 24 were dead, 4 were very seriously ill, 9 were unchanged or slightly worse, 6 were improved, 4 were well, and of 1 there was no record. Of the cases which had died, the duration of life after the first exposure was: in 8 cases under six months, in 7 cases from six to twelve months, in 6 cases from twelve to eighteen months, in 2 cases from eighteen months to two years, and in 1 case two years and seven months. The condition at the time of radiation in the cases which died or which remained very seriously ill was: in 12, that of advanced growth with the patient failing; in 9, that of large growth but general condition good; in 7, that of early growth and general condition good. In 42 out of the whole series of 48 cases he had full notes of the changes in the prostate. In 22, following radiation, there was no decrease in size, hardness, or fixity of the growth; in 15 there was improvement, which was lost at a later date; and in 5 there was improvement which was maintained. The improvement in some of these cases was slight, but in others there was a pronounced change, the hard prostatic mass appearing to melt away, and leaving only hard nodules, though after a period varying from two to six months the induration appeared afresh. In 5 cases, however, the growth disappeared entirely after radiation. One of these patients—an old man—died six months after treatment from gradual failure of the circulation, but there was no recurrence of the growth. The other 4 were alive and without recurrence, and the period since treatment was eight, twenty-one, forty-one, and forty-five months respectively. One of these cases was a rapidly growing endothelioma, the others were of the ordinary scirrhous type. Sir John Thomson-Walker added that with regard to several of the cases which had to be written down as failures he could not help feeling that a very little thing might have changed failure into success. What that factor was—whether it related to the individual patient or to the technique of treatment—could not be definitely stated at the present time, but the advance;

in knowledge had been so rapid, thanks to the splendid work of the radiologists during the past few years, that he looked forward with confidence to a further step towards solution in the very near future.

ACUTE APPENDICITIS.

At a meeting of the Liverpool Medical Institution on March 18th Mr. G. C. E. SIMPSON read a paper on acute appendicitis.

Mr. Simpson stated that, from the Registrar-General's reports, checked by his own knowledge of a small town where he could trace most of the cases of acute appendicitis in the last five years, he had drawn the conclusion that the incidence of the disease was about 1 case per 1,000 of population per annum, with a mortality in cases treated surgically of about 6 per cent. Cases treated throughout on medical lines had a mortality of 14 per cent.; with modern surgery this would be reduced to less than half, if the general peritonitis and abscess cases were submitted to immediate operation and the rest treated medically. The present mortality of the surgical treatment was too high and the careful choice of the time of operation in later cases would give a reduction apart from the reduction to be effected by earlier diagnosis. He quoted recent writings of Sherren and Adams in favour of delay, and of Burgess and Grey Turner in favour of immediate operation, and professed himself a follower of the St. Thomas school. Operating at once on all patients seen in the first two days, on patients seen later in whom the disease was advancing, and as a rule in all children, he used the Ochsner method for doubtful or subsiding cases seen on the third day or later and operated when the condition was quiet. The patients, however, must be kept under close observation and surgical measures be undertaken at once if signs of progression were seen. On these lines his mortality in the Northern Hospital in the last five years was only 2.5 per cent.; adding the figures from the cottage hospital in the small town referred to, it was 3.5 per cent., and in that town the main mortality was in the first year. Of the 15 per cent. of his cases where delay was practised (45 in all) only 6 failed to respond; in 5 abscess required opening, and in 1 gangrene caused the advance. At the subsequent operation no drain was used in 33 cases, although in several there were signs of gangrene, perforation, or abscess, and, in a few, fistula into the intestine. No patient died, but in one of the cases of acute abscess a fistula required treatment. Four other patients operated on by Mr. Simpson had fistulae, and tuberculosis was present in all. Mesenteric or peritoneal tuberculosis was marked in 5 per cent. of the cases and caseating glands were removed in a number. One patient with a tuberculous appendicitis and glands died of tuberculous pneumonia. Typical specimens of appendicitis at various intervals after onset were shown, as were charts of delay cases. Mr. Simpson concluded that the mortality of acute appendicitis could be lowered by judicious choice of the time to operate in cases not seen before the third day, but emphasized the need for the patients to be kept under strict observation and regulation. He considered that this would lead to all suspect cases of appendicitis being kept in the Fowler position and on water only while waiting the advent of the surgeon, and that this, and the opportunities given to students to see more of the symptoms of appendicitis through these cases being detained in the wards, would more than neutralize the ill effects anticipated by Burgess and Grey Turner from applying the treatment to the wrong cases and under wrong conditions.

Immunization in Diphtheria and Scarlet Fever.

Dr. C. Rundle, medical superintendent of the City Fever Hospital, Fazakerley, gave an account of recent work on the use of indicating reactions in, and the prophylaxis and treatment of, diphtheria and scarlet fever. After describing the Schick test, he stated that at birth all infants gave negative reactions and were immune; at the age of 4 years 40 per cent. were still immune, probably for life. Of diphtheria cases 100 per cent. were Schick-positive at the onset of the disease, becoming negative during convalescence. The Schick test was applicable for diagnosis and was probably of more value for this purpose

than throat cultures. If the Schick test was negative the condition was not diphtheria. Active immunization could be effected by the injection subcutaneously of three doses of 1 c.cm. of a toxin-antitoxin mixture at seven-day intervals; immunity was established six months later, lasting certainly for many years and possibly for life. Such an injection produced little or no reaction, and did not interfere with attendance at school. The use of this mixture was of no value in the control of epidemics owing to the length of time which must elapse before full immunity was attained.

Passive immunization developed twenty-four hours after the injection of 1,000 units of antitoxic serum and lasted three weeks. The work on scarlet fever was more recent, but promised equally favourable results.

In the Schultz-Charlton test an intracutaneous injection of 0.2 c.cm. of serum should be made into an area where the rash was well marked—preferably on the trunk; a positive reaction—blanching of an area 1/2 to 1 in. in diameter in four to twenty-four hours—indicated that the case was one of scarlet fever.

In the Dick test 0.2 c.cm. of toxin was injected intracutaneously; the reaction was somewhat similar to the Schick, but developed more quickly and was less lasting. For active immunization three weekly subcutaneous injections of toxin—500, 1,500, and 3,000 minimum skin reacting doses respectively—were given. Immunity developed in two weeks' time and lasted for a considerable period, the limit of which was not at present ascertained. Excellent results had been reported from America, but in this country the reports were so far somewhat more cautious. The results at Fazakerley were interesting; between January and June, 1925, ten probationers had suffered from scarlet fever. In July, 1925, active immunization was adopted for all new probationers; since that date fifty probationers had been appointed, but no case of scarlet fever had occurred among them. Passive immunization of contacts was effected by the injection of 10 c.cm. of antitoxic serum. Therapeutically, 40 to 100 c.cm. of serum was given; this was valuable in early cases, but less valuable later, especially in bad throat cases, probably owing to the presence of a mixed infection in the latter.

ULTRA-VIOLET RADIATION IN MEDICINE AND SURGERY.

At a meeting of the Harveian Society on March 18th, at Paddington Town Hall, with the President, Mr. E. LAMING EVANS, in the chair, a discussion was held on ultra-violet radiation in relation to medicine and surgery. Professor LEONARD HILL, in opening, and Drs. ALBERT EIDINOW and HALLS DALRY, subsequent speakers, set forth in substance the arguments which they used in the similar discussion at the Royal Society of Medicine, reported in the *BRITISH MEDICAL JOURNAL* of April 3rd (p. 617).

Professor LEONARD HILL, after a description of the properties of ultra-violet radiation, enumerated the different kinds of artificial lamps in use. The quartz mercury vapour lamps, while powerful sources, were cold, and might require to be supplemented in treatment by ordinary incandescent lamps for their visible light and dark heat. The mercury vapour lamp could be used readily both for general and local treatment, and was easy of management in the consulting-room. With regard to the carbon arc, he dissented from the dogmatic statement which had been made that nothing but a short-flame arc should be used. With sufficient energy, a long-flame arc was an extremely powerful source of ultra-violet radiation, and enabled very short exposures to be made—a matter of ten minutes—in place of exposures measured by the hour; small doses so spaced as to keep the skin tender and responsive were the best method on which to proceed. The skin had a great power of immunizing itself against ultra-violet radiation. The first effect of such radiation was to thicken the skin. Desquamating skin was an impenetrable barrier, and when there was desquamation it was necessary to wait until this process had ceased and the young and responsive underlying skin could be reached. The more the dose was increased the more strongly would immunization of the skin be

brought into play; therefore, the long and frequent doses which were very customarily given—while not necessarily harmful, because the skin protected itself against excess—were a waste of time. The better way, in general radiation, was to depend on small doses, exposing the chest down to the waist one day, say Tuesday, and on Thursday exposing the back, on the following Tuesday the front of the legs, on the Thursday the back of the legs, and so coming round again after fourteen days to the front of the upper part of the body; that part, having had a mild erythema dose, would have peeled a little, and would present a tender skin ready for another dose. Not more than five or ten minutes' exposure was necessary. With regard to the suggestion that cancer might result from excessive use of ultra-violet radiation, the speaker had found no evidence to support this view among those who worked under arc lights continuously, as in welding and photography; Bernard of St. Moritz, a pioneer of heliotherapy, had found no evidence of epithelioma of the skin occurring among guides, postmen, and others exposed to this radiation in high Alpine regions. Another common fallacy concerned pigmentation; it had been claimed that pigment acted as a kind of sensitizer or transformer of the radiation; but it had yet to be proved that pigment had any function other than that of a screen. He concluded with the general observation that ultra-violet radiation was of importance as a help to general treatment, but, like everything else, it would fail in a number of cases; much clinical work was still needed to discover the cases for which it was suitable or unsuitable.

Dr. GORDON PUGH (Medical Superintendent, Queen Mary's Hospital for Children, Carshalton) considered that some of the claims for heliotherapy, and especially phototherapy, appeared to be rather extravagant. It was necessary to consider whether any new therapeutic principle was being introduced, or whether the old-established healing agents, such as fresh air, surface hyperaemia, and counter-irritation, were not appearing here in another and perhaps more convenient form. In his hospital at Carshalton three methods of treatment were in use. The first was open-air treatment, which he might call, on the authority of Sir Robert Jones, a method of British origin, the first hospital for the complete open-air treatment of surgical tuberculosis being the Baschurch hospital, founded in 1902. The second method was heliotherapy, which might be called the Swiss method, since it owed its popularity to the efforts of Dr. Rollier, who began using general sunlight baths in 1903. The third was phototherapy, which might be regarded as Danish, having been started in 1894 by Dr. Finsen; it was rendered more generally available by Kromayer in 1904, with the introduction of the mercury vapour quartz lamp, and by Reyn in 1913, who added to local treatment general irradiation by the carbon arc. After showing photographs illustrating the satisfactory results obtained at Carshalton in surgical tuberculosis, marasmus, and rickets, by the open-air method, he went on to speak of heliotherapy, which might be regarded as an improved form of open-air treatment, the presence of sunlight encouraging and rendering easier the application of the open-air method. Rollier believed that sunlight was the important factor rather than the open air, his main argument being that the deeper the pigmentation the better the prognosis. On this theory pigment appeared to be regarded as a transformer of light energy into the energy spent in some chemical reaction useful in defence. Dr. Pugh's observations at Carshalton did not confirm this theory. In 1922 a careful note was made of the pigmentation of 232 cases of tuberculosis of the spine, hip, and knee, many of them severe cases with sinuses. Three and a half years later, when all except a few convalescent cases were either cured or dead, the cases were classified according to the results, and the mortality among the "very good" pigmenters was found to have been 16 per cent., among the "good" pigmenters 15 per cent., among the "slight" pigmenters 10 per cent., and among the non-pigmenters 9 per cent. He regarded these observations as disproving Rollier's theory, and he was of opinion that Professor Hill had reached the solution when, in 1922, after an investigation conducted in collaboration

with Dr. Argyll Campbell,¹ he said that, while not disputing the value of heliotherapy as a factor in the arrest of the disease, the benefit of heliotherapy as applied at Alton was to be attributed to the great rise in metabolism due to the cooling power of the open air, while the rise due to sunlight *per se* was insignificant, but that sunshine promoted evaporation from and flow of lymph through ulcers and discharging sinuses, and also warmed the diseased parts exposed to it. Professor Hill had modified his views since then, but so far the speaker had not seen any clinical reason to do so. It seemed possible to explain all the benefits received from heliotherapy as being produced partly by suggestion, partly by the increased metabolism induced by very free exposure to the air which heliotherapy involved, partly by surface hyperaemia and the resulting lymphorrhoea, and partly, as in rickets, by vitamin D through the action of the sun's rays on cholesterol. The subjective effects of artificial light in treatment were more marked than the objective; but on the objective side three effects had to be considered. The first was hyperaemia of the surface, which conceivably might lead to a reduction of high blood pressure by vaso-dilatation, to lymphorrhoea, which would assist in the healing of ulcers and superficial sinuses, and to improvement in abnormal skin conditions, such as eczema and psoriasis; the second factor was the production of vitamin D by the action of rays on cholesterol; and the third the increase, short-lived, in haemo-bactericidal power. Dr. Pugh then showed a large number of photographs of patients before and after thirty to eighty sittings with the carbon arc. In one case of glandular abscess of the neck with reddened undermined skin over it and a small discharging sinus, the undermining had continued to extend; but in similar cases in which the undermined skin was cut away and the lesion scraped, and in other superficial sinuses and ulcers connected with tuberculous phalanges and tarsal bones, healing was definitely hastened by the light baths, especially when there had been previous scraping. Sinuses connected with deeper structures, such as the spine and hip-joint, in which help was specially desirable, showed no improvement, and an old empyema sinus remained unchanged. In some cases the Murray Leick red-ray lamp was used for superficial ulcers and appeared as efficacious as the carbon arc, if not more so. A severe case of acute general eczema, after two months' ineffective treatment by ointment, was given carbon arc irradiation; it was brought under control after twenty-nine baths in three months, and a month later was quite cured, but two other cases of eczema still under treatment showed little or no improvement. A patient with psoriasis had not improved after forty carbon arc baths; one of the larger patches was then blistered by the Kromayer lamp, and was found to have completely disappeared when the scab separated. Several cases of extensive lupus which had been given many carbon arc baths showed no benefit beyond a cleaning up of the surface. The speaker attached some value to Mr. Sampson Handley's suggestion that radium gamma rays should be used around the circumference of the area to excite an aseptic lymphangitis and obliterate the lymphatic vessels around the infected region, so providing a barrier against spread. Dr. Pugh had used gamma rays in the treatment of tuberculous adenitis during the past three years with very satisfactory results. It had been said that light treatment increased the haemo-bactericidal power, and that this might put up the general resistance of the body to disease. So far as infectious diseases were concerned, this had not been confirmed at Carshalton. Epidemic catarrh and chicken-pox, when introduced into wards, had affected patients indiscriminately, whether they were receiving light treatment or not, but open-air treatment limited the spread of infections. He had been informed by Dr. H. T. Woodfield, of the Park Fever Hospital, Hither Green, that his impression, after using ultra-violet light in twenty cases of whooping-cough, was that good was done in the early stages, but that, when the disease was well established it was not influenced by light treatment. His results had been inconclusive, in the case of diphtheria carriers. The speaker hoped that the introduction of phototherapy into city hospitals would not lead to delay in the transfer of cases of surgical tuberculosis to institutions in the country.

¹ BRITISH MEDICAL JOURNAL, February 25th, 1922, p. 301.

Dr. A. EDINOW gave particulars of experiments which showed the importance, whatever form of light treatment was adopted, of taking care as to the area of skin exposed to each dose. If a patient had been given a dose of light, and erythema was produced, immunity developed very quickly. When a small area of skin was exposed and an erythema produced, a similar erythema dose on the following day would produce no intensification, the maximum reaction having been reached. It was necessary to wait some time until the skin returned to its normal state and again became sensitive to ultra-violet radiation; it was futile to continue light treatment without observing the state of the skin.

Dr. GRAY HILL, referring to the fact that small exposures to the arc light produced a multiplication of cells, asked whether it was not possible that big doses of sun rays, as in the Alps, would bring about their own protection, and that small doses might possibly produce epithelioma in persons who had not thus become immune.

Dr. HUMBERT ODDY said that his own experience was that pigmentation in the majority of cases gave no criterion of the results of treatment. Light treatment had been overdone, and claims had been made for it which could not be substantiated. Moreover, many unqualified people were now practising the treatment, which would lead sooner or later to its undeserved disrepute. Nevertheless, he thought that Dr. Pugh was unnecessarily pessimistic.

Dr. HALLS DALLY said that he had had a good many cases under treatment at Mount Vernon with a view to seeing whether high arterial pressure could be lowered or low pressure raised, and on the whole he had had very gratifying results with ultra-violet radiation alone. He thought this was due to the effect of the carbon arc on metabolism.

Professor LEONARD HILL, replying on the discussion, said that he was at one time very much of Dr. Pugh's way of thinking. At first he was rather incredulous of all the statements concerning heliotherapy, but he had had to modify his views. He was now fully persuaded that light as well as the open air had a very powerful action and could be of great use. He related some remarkable cases which had come under his observation in the light ward at the New End Hospital, Hampstead. It was true that there were failures, but there had been many successes. With regard to metabolism, respiratory metabolism was increased remarkably by cooling wind, but not by ultra-violet radiation; this latter, however, might produce a slow effect on the general metabolism. Some cases of high blood pressure might be improved by arc light treatment of a source of chronic infection.

JAMES MACKENZIE INSTITUTE FOR CLINICAL RESEARCH, ST. ANDREWS.

IRREGULARITY of the pulse in youth was the subject of a lantern lecture by Dr. J. H. P. PARON on March 23rd. Mackenzie had pointed out that it was a physiological phenomenon of youth, which became exaggerated in convalescence from febrile illness. It tended to disappear in some febrile complaints, and its return was evidence that the toxic process causing its disappearance had become quiescent. The irregularity was absent only in four instances in 500 consecutive girls whom the lecturer had examined on admission to school; each of the four in whom it was absent was found to be suffering from a febrile complaint. He concluded from these facts and a large number of observations spread over some years that the irregularity was never absent, except in disease in girls from 8 to 16 years of age. Its absence was a valuable sign of ill health, and its return in a marked form in convalescence had the same significance as the fall of temperature, indicating that active toxæmia had ceased. This fact was evidently not generally known, since it was common for young persons to have their activities restricted because of its presence. The terms "arrhythmia" and "irregularity" carried a significance of abnormality, which was doubtless the reason why Mackenzie's view had not received wider recognition, whereas absence of the irregularity was the symptom of disease.

METHODS AND PROBLEMS OF MEDICAL EDUCATION.

AMONG the Rockefeller Foundation's numerous activities in connexion with its appropriate motto, "The well-being of mankind throughout the world," is the collection and circulation, by its Division of Medical Education, of knowledge concerning *Methods and Problems of Medical Education*.¹ The third series of this useful evangel has recently been published, and contains nineteen articles on nine branches of medical science. Each article is written by a professor or teacher in a department, and gives in detail, with a generous allowance of illustrations and plans (173 in all), the structural arrangements of the laboratory buildings, the working arrangements, and the composition of the staff—in fact, just the information necessary to assist a professor who is faced with the task of organizing a department and of advising the architect about the building of a laboratory. The problems of medical education are incidentally discussed in connexion with the descriptions of the methods of instruction, but the outstanding value of this collection of these reports from nineteen centres of medical instruction in seven countries (United States, Canada, England, France, Germany, Holland, and China) is the full account of the structure and equipment of modern laboratories and of the various methods of teaching employed. Of the nine branches of medical science represented by the departments described, two are clinical: Professor Louise McIlroy gives a full account of the Obstetrical and Gynaecological Unit of the Royal Free Hospital, and Professor Adrian S. Taylor of his department of surgery in the Peking Medical College. The other seven subjects are more extensively illustrated by two or more reports from the laboratories in each category, and so a wider vista of the methods and equipment is provided. Thus there are made known the physiological departments of the University of Cambridge (described by the late Professor J. N. Langley), of Harvard, of Groningen, and of the Western Reserve, Cleveland; in the last Professor Carl Wiggers attractively shows how the instruction in the physiological laboratory is correlated with the later clinical work; metabolism experiments, gas analyses, and electro-cardiography thus add a broader significance to the simpler signs and symptoms of disease. Professor L. B. Mendel, in describing his department of physiological chemistry, points out that physiology at Yale is divided into physical and chemical physiology, and that the latter has a somewhat broader content than the so-called biochemistry taught elsewhere as an adjunct to chemistry. In his account of the biochemical department of the Peking Union Medical College, Professor Hsien Wu finds that of the pre-clinical subjects the best adapted for teaching the scientific methods of inquiry, and for counteracting the Chinese student's tendency to learn results by heart, is biochemistry. The place of pharmacology in the medical curriculum and its focusing of the biological sciences and cementing them to clinical work are discussed by Professor Torald Sollmann of the Western Reserve University. The vast field of old-time *materia medica* in China offers a unique opportunity for research in order to sift their value, and this is being undertaken in the pharmacological department of the Peking Union Medical College. The methods of teaching human anatomy are described by Professor T. Wingate Todd of the Western Reserve University, by Professor J. A. J. Barge of Leyden, Professor Hans Bluntschli of Frankfurt-am-Main, and by Professor André Forster and Professor P. Bouin of Strasbourg, the latter dealing with histology. At the Western Reserve University neurology, as elsewhere in America, forms part of the second year's study, and serves as a co-ordinating course preparatory to physiology; the lecture course covers general animal behaviour and the elements of psychology. A very interesting feature of this department is the Hamann

¹ *Methods and Problems of Medical Education*. (Third Series.) New York: Division of Medical Education of the Rockefeller Foundation. 1925. (8 x 11, pp. 242; 173 illustrations.)

Museum of Comparative Anthropology and Anatomy, which contains about a thousand complete human skeletons, with anthropometric, photographic, clinical, and personal data, thus providing unique opportunities for teaching and research.

Professor W. G. MacCallum of the Johns Hopkins, Professor H. T. Karsner of the Western Reserve, and Professor Horst Oertel of the McGill Universities, give extremely interesting accounts of their pathological departments. At the Johns Hopkins a year was occupied in making plans for the new eight-storied laboratory, opened November 1st, 1923, which was designed to meet the needs and allow almost any changes necessary for those working there twenty years hence. Arrangements were made for the study of the morbid anatomy and the chemical and experimental pathology of plants as well as animals. Notable features are the careful indexing and preservation of material from the six hundred or so necropsies in the year, and the weekly conferences, especially those held for many years by Professors MacCallum and Thayer to correlate methods of clinical diagnosis with the conditions found after death. Material from four thousand necropsies is preserved in the laboratory for teaching purposes, and small groups of six or seven students are taken by instructors in an intensive and informal manner. At the Western Reserve University the clinical bearings rather than the purely scientific aspects of pathology are emphasized, and the physiological and experimental aspects of disease are fully demonstrated. At McGill University medical jurisprudence is, much to its advantage, closely associated with the Pathological Institute. The work is chiefly based on pathological morphology, for Professor H. Oertel considers this indispensable if a grasp of pathological function is to be obtained, and more important in this respect than normal anatomy and histology are to normal physiology, for he holds that pathology is far from being applied physiology.

These reports of the various departments of medical education may with advantage be read in conjunction with Mr. Abraham Flexner's *Medical Education: A Comparative Study* of medical education in Europe and America, published last year. From both these publications, and especially Mr. Flexner's, the important principle of correlation between the various constituents of the medical curriculum should be drawn.

PSYCHIATRY.

THE Morison Lectures for 1925 on *Mental Invalids*,² delivered before the Royal College of Physicians of Edinburgh by Dr. C. C. EASTERBROOK, contain a number of interesting discussions on practical psychiatric problems which have engaged his special attention during thirty years' experience in mental work. The subjects considered are the body-mind; the clinical examination of mental invalids; the causation of mental diseases, with some remarks on their prevention; the classification of mental disorders; and some aspects and methods of curative treatment. Many of the writer's observations might be made the subject of comment, but special reference may suitably be made to the account given of the sanatorium treatment of active psychosis by rest in bed in the open air, since Dr. Easterbrook is himself responsible for the introduction of this mode of therapy into mental hospitals. Though the value of "rest and open-air" treatment in the acute psychoses is now generally recognized, the arguments advanced in its favour were not altogether accepted by psychiatrists when Dr. Easterbrook read his original paper on the subject nearly twenty years ago, and at that time "active exercise" was the conventional method of treatment for many of these cases. It is particularly interesting to read this paper again, because the writer appears to have sensed the importance of air and sunlight in the treatment of illness generally, and stated that there was a pressing need for the further elucidation of this subject. Recent work has, of course, fully confirmed his views, and his

² *Mental Invalids: Being the Morison Lectures delivered before the Royal College of Physicians of Edinburgh in June, 1925.* By C. C. Easterbrook, (M.D., F.R.C.P.S., Edinburgh and London: Oliver and Boyd. 1926. (Med. Rev. no. 66. 5s. net.)

original remarks may perhaps be usefully repeated in reviewing these lectures. He wrote as follows:

"The *modus operandi* of rest is comparatively simple; that of the open air is more complicated, and herein lies a wide and worthy sphere for the investigator—the pharmacodynamics of the fresh air of the open as a remedy for the preservation of health and the cure of disease. The fresh air has an undoubted soothing and soporific influence on the nervous centres, and the cooler outdoor atmosphere stimulates general bodily metabolism and appetite, both of which effects render the open air of special value in the treatment of active insanity. But in the treatment of the insane, and, indeed, of the sick in general, by exposure to the fresh air of the open, we cannot overlook the concomitant operation of such beneficent influences as the soothing action of soft breezes playing over the features, the comforting effect of the pleasant sounds and prospects of Nature and her surroundings, as commonly associated with the life in the open, the cheerful influence of sunshine, the health-giving action of the ozone and oxygen and possibly other gases of the atmosphere, and the more obscure influences of light, sound, electricity, heat and cold or temperature, humidity, atmospheric pressure, and the like. Indeed, to arrive at the rationale of open air in the therapy of disease, we must take into consideration the entire gamut of its mechanical, chemical, and physical properties and conditions, as regards the influence of which on the human organism for good or the reverse there is now almost a pressing need for further elucidation." (*Journ. Ment. Sci.*, October, 1907.)

The lectures in the volume before us will naturally be read with interest by psychiatrists, but they are written simply and clearly and contain many observations which the general practitioner will find helpful and informing.

DR. T. WADDELOW SMITH, deputy medical superintendent of the City Mental Hospital, Nottingham, has written a volume entitled *An Introduction to the Mind in Health and Disease*,³ which is intended for students and general practitioners interested in mental work. Part I deals with the anatomy, physiology, and functions of the nervous system, and with normal psychology; Part II with psychopathology, classification, principles of treatment, and the various forms of mental disease. The book thus covers the ground of the ordinary textbook, but the subject-matter is greatly condensed, and the author only intends his work to act as a stimulus for further study. His aim is to present a biological conception of mentation, and for this reason he devotes much attention to the neurological basis of psychological phenomena. Dr. Smith might with advantage have expanded his theoretical views and have omitted the clinical section, which is scanty and inadequate. Thus the treatment of general paralysis is compressed into three lines, and no reference is made to the malarial treatment of this disease.

DRS. EDWARD A. STRECKER and FRANKLIN G. EBAUGH are conjointly responsible for a volume entitled *Practical Clinical Psychiatry for Students and Practitioners*.⁴ They have selected the method of actual case presentation as the most helpful and practical for the beginner. Concrete examples of the various psychoses and neuroses are given, and are followed by discussions in which the salient features of causation, symptomatology, modifiability, and treatment of the diseases under consideration are reviewed. The first three chapters deal with general etiology, diagnosis, prognosis, and treatment; classification of mental diseases; and methods of examination. References to the literature are given at the end of each chapter, and a glossary is provided at the end of the volume. The beginner in psychiatry will find this book a most useful guide in his clinical work; it is clearly and attractively written, and we can recommend it to clinical assistants or junior medical officers engaged in work in psychiatric clinics or mental hospitals.

DR. RENÉ CHARON has written *La Psychiatrie en Clientèle*⁵ with the intention of providing a simple, clear, and brief guide to psychiatry for the use of the general practitioner. In his preface he expresses regret that the medical profession generally takes so little interest in mental disorders. He asserts that mental patients are increasing in numbers

³ *An Introduction to the Mind in Health and Disease.* By T. Waddelow Smith, F.R.C.S. Eng. London: Baillière, Tindall and Cox. 1925. (Demy 8vo, pp. viii + 236; 6 plates. 10s. 6d. net.)

⁴ *Practical Clinical Psychiatry for Students and Practitioners.* By Edward A. Strecker, A.M., M.D., and Franklin G. Ebaugh, A.B., M.D. Philadelphia: P. Blakiston's Son and Co. 1925. (Demy 8vo, pp. xvi + 375; 24 figures.)

⁵ *La Psychiatrie en Clientèle.* By René Charon. Paris: A. Maloine et Fils. 1924. (Gr. 8vo, pp. xi + 152; 2 figures. 8 fr.)

and that their antisocial reactions are becoming more frequent and numerous. For these reasons he considers it essential that all practitioners, in matters of psychopathology, should be in a position to make a practical diagnosis, to establish a judicial prognosis, to formulate useful treatment, to uphold medico-legal conclusions, and to assist in the dissemination of the principles of mental hygiene. Dr. Charon has succeeded in writing in quite simple language a book which the French practitioner will no doubt find very useful in dealing with his mental patients.

DISEASES OF THE NERVOUS SYSTEM.

DR. CAMPBELL THOMSON's well known handbook on *Diseases of the Nervous System* has recently been revised* with the collaboration of Dr. Riddoch, and the joint authors may be congratulated on their success in bringing it up to date and providing at a reasonable cost a concise and easily read manual for the student.

The additions, in the shape of fresh chapters on methods of examination, compression paraplegia, acute traumatic lesions of the spinal cord, and subarachnoid haemorrhage, will enhance the value of this new edition. Some new illustrations and figures are also provided. In a work of this scope it is not easy to know what may be omitted, but we think that a more detailed account of the whole subject of the source and changes of the cerebro-spinal fluid in disease would have been of benefit to the student reader.

The earlier chapters on anatomy and physiology and methods of examination are brief but lucid, and form a well balanced introduction. No fault can be found with the presentation of the later material in the book, and the description of the various forms of neuro-syphilis is especially well given for a small textbook.

The fourth edition of this now well recognized manual may be safely recommended as a valuable and handy guide to the student.

NEUBURGER'S "HISTORY OF MEDICINE."

THE appearance of Dr. ERNEST PLAYFAIR's translation of Professor MAX NEUBURGER's *History of Medicine* has been much delayed. The first volume, which was fully reviewed in our columns (1912, ii, 445) fourteen years ago, dealt with the progress of medicine up to the Renaissance, and the first part of the second volume, which is much smaller, is now before us. It is devoted to the early and late Middle Ages. Barbarism and the stagnation of science in the early Middle Ages was relieved only by the attitude of the Church whereby monasticism prevented the complete annihilation of culture, and as a result medicine came more under clerical sway in the epoch which has been described as that of monastic medicine.

The chapter on medicine in the eleventh and twelfth centuries describes the Salernitan School as the starting-point, after five centuries of lethargy, of activity in medicine in the West, and as its connecting link with the medicine of antiquity and of the Orient. Though there have been several conjectures, there is no certainty about its origin except that it was not an ecclesiastical foundation. The famous "Regimen sanitatis Salernitanum," originally consisting of 362 leonine verses, eventually grew to tenfold the size, but probably everything in it other than the part on diet was an addition. At the end of the twelfth century the School of Salerno revived on a scientific basis the art of surgery, but the influence of Arabic on Western medicine was long resisted by that School. In the thirteenth century, however, Arabism became dominant in the universities, where medicine now for the first time attained a position of equality with other branches of knowledge. The section on the state of medicine in the later Middle Ages shows that medical scholasticism and Arabism, with

their attendant astrology and uroscopy, were carried to extremes and thereby cramped research. This instalment of the work ends with an historical survey of the literature of the fourteenth century.

Dr. Playfair has done his work so admirably that we look forward with pleasure to the completion of this valuable work, which was sadly interrupted by the great war.

A MEDICO-POLITICAL LITERARY ESSAYIST.

ACCORDING to his introducer, Mr. Arthur Ponsonby, M.P., Dr. W. C. RIVERS has an irrepressible critical faculty for literature, and while fully occupied with his professional work had to subordinate his desire for literary expression. Now, however, under the title *Through a Consulting Room Window*,¹ Dr. Rivers has gathered together literary and other essays which he has contributed to various journals, from the *Cambridge Magazine* to the *London Mercury*, from the *New Statesman* to *The Hospital*. Of the extent of Dr. Rivers's reading there can be no doubt; on the merits of authors he is very decided in his opinions. Mr. Ponsonby says "he is provocative, but he is never dull." Dr. Rivers thinks little of Mr. Rudyard Kipling as a writer or of Mr. Bernard Shaw as a dramatist. One has imagination without intellect, the other intellect without imagination. Poor Mr. Kipling is merely an articulate boy scout, comparable to Marie Corelli, the articulate servant girl; while Mr. Shaw's St. Joan is only the young lady Fabian in *Fanny's First Play*, talking common sense didactically. To Dr. Rivers the five great world novels are *Le Père Goriot*, *Madame Bovary*, *Vanity Fair*, *La Chartreuse de Parme*, and *Anna Karenina*. He has something to say on physiognomy, and the remarkable resemblances, as of types, which are occasionally met. He discourses on the kinship of the artist with the savage, contrasting with the former the man of science, "whose type is as a rule not primitive at all." The author describes a brief meeting with Henry James; and in an essay entitled "Smudged country" he deplores the squalor which follows the growth of industrialism in this country, and pleads for the merging of the Universities of Birmingham, Sheffield, and Leeds in a new University of Stamford. Two of Dr. Rivers's essays are on medical subjects. In "Medical women in the future" he gives reasons why, under the Socialist system he evidently regards as at hand, there may not be much opportunity for the practice of medicine by women. In "A medical portrait or two" we have a eulogy of a well known bacteriologist as a hero; a contemptuous portrait of "Sir Thomas Wilkins," a humbug; a criticism of some ideas about nurses; a description of the sad life of the present-day general practitioner, with a forecast of his glorious future as a salaried, pensionable, efficient medical man; and an exposition of the nature of the quack's friends. From all this something may be gathered about Dr. Rivers's views, political and otherwise.

NOTES ON BOOKS.

AN extensive knowledge of chemistry would be needed to guard against all chances of prescribing incompatibles. A handy book of reference may therefore be useful whenever the question of compatibility arises. One of the most useful we have seen is RUDDIMAN'S *Incompatibilities in Prescriptions*.² The author has anticipated almost every kind of question. He presents a table of the solubilities of more than 700 drugs in water, alcohol, ether, chloroform, and glycerin, with an additional note where needed on a special solvent. The information will be most useful to the prescriber, for the solubility of a drug must often be the first consideration in choosing the mode of exhibition. The table indicates, moreover, the cases where decomposition is suffered by dissolution in particular solvents. Incompatibilities are described both generally and particularly under the separate headings of the individual drugs. The scheme

* *Diseases of the Nervous System*. By H. Campbell Thomson, M.D., F.R.C.P. Lond., and George Riddoch, M.D. Aberd., F.R.C.P. Lond. Fourth edition, revised. London and New York: Cassell and Co., Ltd. 1925. (Cr. 8vo, pp. xvii + 541; 102 figures, 24 plates. 16s. net.)

¹ *History of Medicine*. By Dr. Max Neuburger, Professor of Medical History in the University of Vienna. Translated by Ernest Playfair, M.B., M.R.C.P. In two volumes: Vol. II, Part I. Oxford Medical Publications. London: Humphrey Milford, Oxford University Press. 1925. (Cr. 4to, pp. vii + 135. 7s. 6d.)

² *Through a Consulting Room Window*. By W. C. Rivers. With an Introduction by Arthur Ponsonby, M.P. London: Methuen and Co., Ltd. 1925. (Fcap. 8vo, pp. xv + 195. 6s. net.)

³ *Incompatibilities in Prescriptions*. By Edsel A. Ruddiman, Ph.M., M.D. Fifth edition, rewritten and reset. New York: J. Wiley and Sons, Inc.; London: Chapman and Hall, Ltd. 1925. (Demy 8vo, pp. vii + 330. 12s. 6d. net.)

renders the context easy for reference, and the remarks are so well co-ordinated as to afford instructive reading. These articles would alone make an excellent treatise on the subject, but the value of the book is increased by copies of 480 selected prescriptions demonstrating as many cases of special incompatibility. Each case is discussed at length, the effects of varying methods of procedure being described and a solution of the difficulty indicated. These prescriptions, which should be particularly instructive to students, are arranged apart from the sections relating to them and can accordingly be used as a set of exercises. The explanatory notes are contained in subsequent pages under numbers corresponding with the number of the prescription. There is also a separate index for finding each of the combinations of drugs discussed. The treatment of the subject is sound all the way through. The book cannot fail to be helpful to the prescriber and should be accounted an imperative necessity to the dispenser; it is so replete with uncommon information that it must prove useful to all who are concerned with the chemical properties of drugs.

A new (seventh) edition of LUFF and CANDY'S *Manual of Chemistry for Medical Students*¹⁰ has made its appearance. As is very well known, it is a book for beginners. The authors have aimed at being instructive, and though there is no scarcity of facts every fact is clothed with interest. The first volume deals with inorganic chemistry; here it occurs to us to suggest, however, that instead of a theoretical discussion on atomic weight it might have been better to have given a statement of the law of constancy of proportion of combining equivalents as the first introduction to the concept of the chemical atom, not merely because that was the historical basis of the atomic theory, but because it presents the simplest considerations for its foundation. The characteristics of the atom as a unit would find a more obvious explanation after its purely chemical behaviour is understood. This is, however, a matter of opinion. The book is written expressly for medical students, and contains exactly the material they need, as well for the examination course as for education. The second volume is concerned with organic chemistry. We find this equally commendable and in the same general terms. Every attention has been given to rendering the treatise informative on those particular facts which connect organic chemistry with the study of medicine. This form of treatment is a pleasing contrast to that in which a formula, trimmed with melting and boiling points, is made to serve for the description of a substance. We do not say there is no room for improvement: the best of books contain many sentences that could have been better expressed, but the only room for improvement we could desire lies in directions already well begun. It is a compact and handy little treatise, well suited to its purpose.

A second part of Dr. MARY BLACKLOCK'S *Elementary Course in Tropical Hygiene*¹¹ has now been published, and more than maintains the interest awakened by the first part, which was noticed a few weeks ago (February 27th, 1925, p. 383). Part II aims at instructing school children somewhat older than those for whom Part I was written. It comprises a series of lessons on the value of hygiene and on the ways in which disease is brought about when sanitation is neglected. Appended to several of the chapters are suggestions for class work which teachers can readily amplify by the use of material which every tropical village can provide. Heads of the Departments of Education in the various colonies would do well to introduce this small work into their schools and prevail upon the teachers to make the subjects treated part of the regular curriculum. Inculcation of these simple health measures to the young would do much to remove the senseless opposition of the adult native to measures formulated for his own advantage and thereby assist greatly in easing the "white man's burden."

The British Social Hygiene Council, formerly the National Council for Combating Venereal Diseases, has started an official journal—*Health and Empire*.¹² The first number is

¹⁰ *A Manual of Chemistry for Medical Students*. By Arthur P. Luff, C.B.E., M.D., B.Sc. (Lond.), F.R.C.P., F.I.C., and Hugh C. H. Candy, B.A., B.Sc. (Lond.), F.I.C. In two volumes. Vol. I, Inorganic Chemistry; vol. II, Organic Chemistry. Seventh edition. London: Cassell and Co., Ltd., 1925 and 1926. Fcap. 8vo. Vol. I, pp. xii + 573; 57 figures. 11s. net. Vol. II, pp. vii + 267; 12 figures. 6s. net.

¹¹ *An Elementary Course in Tropical Hygiene. Part II*. By Mary G. Preface by Andrew Balfour, C.B., C.M.G., on: John Bale, Sons and Danielsson, Ltd. res. 2s. 6d. net.)

¹² *Health and Empire*. The Journal of the British Social Hygiene Council, Inc. Vol. I, No. 1, March, 1926. Published quarterly; price 2s. 6d., or 10s. per annum, postfree. London: Constable and Co., Ltd.

promising. It contains well written and interesting articles, and it is well produced. The editorial comments deal with the imperial aspect of social hygiene and illustrate the wider outlook of the Council under its new name. Notes are made on the Imperial Social Hygiene Congress held at Wembley last October; the action of the League of Nations regarding venereal disease in the African mandated territories; the prevention and treatment of venereal disease in British colonies and protectorates; and the employment of police-women in England. A valuable article on the "Contribution of psychology to social hygiene" comes from Professor Cyril Burt. After dealing with juvenile delinquency and vocational guidance, he considers sex delinquency and the psychological causes of prostitution. He concludes that prostitution, as such, will slowly vanish; and it will vanish as it has appeared—not for financial reasons, but for psychological. There is likely to arise, he thinks, at any rate temporarily, a more general tendency to promiscuity. But eventually civilization will succeed in sublimating the instincts of sex. Professor T. Percy Nunn contributes an article on the "Influence of education and tradition in social hygiene." He insists that we must seek through genuine, if simple, biological teaching in the elementary, and even more in the secondary, schools to correct the orientation of the national mind. Mr. C. J. Bond reinforces the argument from the medical standpoint in a paper entitled the "Attitude of the State and society to antisocial diseases." A report is given of the conference held in the County Hall, London, in February last on seamen and venereal disease. The issue concludes with reviews of a number of books and of official publications. This first number sets a high standard, which it may be hoped will be maintained.

The 1926 edition of the *Yearbook of the Universities of the Empire*¹³ has been slightly reduced in size, and certain alterations have been made in its contents. As in former years, details about the universities of the Empire are set out systematically. The brief notes about the principal foreign universities, which appeared in the previous issues, 1921-25 inclusive, have been discontinued in the present volume, with the exception of accounts of universities in the United States, which, it is stated, are retained owing to the recent increase in the number of scholarships for British students tenable in that country. The appendix contains a list of centres of research outside the universities and university colleges, with notes on the opportunities available at them for visitors from outlying parts of the Empire. Another section of the appendix indicates the respects in which certain universities and professional schools undertake individually special work not common to all—as, for example, veterinary and commercial science, journalism, and architecture. This section also gives an account of post-graduate courses provided in different subjects.

¹³ *Yearbook of the Universities of the Empire, 1926*. Edited by W. H. Dawson, and published for the Universities Bureau of the British Empire. London: G. Bell and Sons, Ltd. 1926. (Cr. 8vo, pp. xii + 792. 7s. 6d. net.)

PREPARATIONS AND APPLIANCES.

Apparatus for Light Treatment.

A CATALOGUE of about seventy pages, setting out the construction and uses of various lamps for heliotherapy and ultra-violet treatment, has been sent to us by John Bell and Croyden, Limited (incorporating Arnold and Sons), of 50, Wigmore Street, London, W. It gives a useful general description of the spectrum of solar energy, the character of ultra-violet radiation, and the terms in common use to indicate wave-length. Its aim is to describe a selection of lamps suitable for all the purposes for which artificial sunlight or ultra-violet radiation is now applied, without, of course, discussing the advantages of the different methods of treatment. Four lamps are specially mentioned: a single arc lamp, used generally with an electrically controlled pair of carbons; a quartz mercury arc, which may have to be supplemented by other lamps to make up for the absence of heat rays; a tungsten arc in the form of a hand-lamp for local treatment, with electrodes which may be of pure tungsten or of carbon in which tungsten is impregnated; and a quadruple arc sun-lamp, one model of which is designed so that fifteen patients may be treated at one time. For this lamp, which bears the name of "Arnold," the makers claim that the output of ultra-violet rays is in excess of that from any other form of lamp, and that, with the selection of suitable electrodes, the exposures, instead of being measurable by hours as in some forms of light treatment, may be reduced to ten minutes. A drawback to ultra-violet therapy at present is the absence of any satisfactory method of dosage, but the catalogue includes a pigmentation meter and other devices in the same connexion.

SATURDAY, APRIL 10TH, 1926.

THE ECONOMY BILL AND NATIONAL HEALTH INSURANCE.

Nor much enlightenment is to be found as a rule in an all-night debate in the House of Commons, and the discussion on the Economy Bill in Committee was no exception. The Government had declared its intention of securing the passage of the first two clauses of the bill during the sitting, but the tactics of the Opposition prevented the passage of more than Clause 1. These two clauses are the most important for the medical profession. The effect of the first clause had been explained on the second reading of the bill both by the Chancellor of the Exchequer and by the Minister of Health. The admirable speech of Mr. Chamberlain should have enabled the House to obtain a true perspective, but those members on both sides of the House who, for the time, constituted themselves the spokesmen of the Approved Societies do not seem to have got beyond denunciations of "robbery" and "breach of faith." It is important, but apparently not quite easy, to discover exactly how these two clauses affect national health insurance finance and the proposals of the Royal Commission for extensions of the benefits for insured persons.

The present State grant is two-ninths of the sums expended in benefits of all kinds and cost of administration. The financial basis of the system is to be varied, as indicated by the Government actuary, mainly on the grounds that interest is earned at a higher rate, and incapacitating sickness is at a lower rate, than that originally provided for. In addition there is the fact that from 1928 onwards there will be considerable relief to the fund, as insured persons will then be in receipt of old age pensions at the age of 65 years instead of 70 years. On this new basis the sums available from the contributions of insured persons, their employers, and the State will be about four and a half million pounds more than is necessary to meet the anticipated expenditure on current statutory benefits. Clause 1 of the Economy Bill proposes to reduce this excess by about one-half by making the proportion of State contribution, not two-ninths as now, but one-seventh in the case of men and one-fifth in the case of women. The State contribution to additional benefits will be reduced in like proportion, thereby relieving the Exchequer to the extent of about another half-million pounds each year. It will be seen that this reduction of State grant does not endanger any of the statutory benefits to which insured persons are entitled.

It will be remembered, however, that the Royal Commission recommends that there should be extensions of statutory benefits "as and when funds are available" in the following order of priority: (a) a consultant and specialist service and laboratory services, (b) the provision of allowances to the dependants of incapacitated insured persons, (c) improved provision for maternity, (d) dental treatment. These extensions were to be financed by means of a pooling of half the future surpluses of Approved Societies, but it was, of course, assumed that sums so expended on these extensions would be supplemented by a State grant in the present proportion. A natural inquiry, therefore, is whether the reduction in the proportion of

the State's quota will affect these extensions. The Royal Commission contemplated that the first two of the above extensions would become "immediately practicable," while the other two would have to be postponed for some indefinite period. It was estimated that the cost of the consultant and laboratory services for the whole of Great Britain would be some one and a half million pounds per annum. There does not seem to be any reason to suppose that the provision of the necessary sum will be affected by the proposed alteration in the proportion of the State grant; it may be assumed, therefore, that the extension of the scope of medical benefit to include such services is not endangered by this change. In the absence of more detailed information, however, it is doubtful whether this can be said also of the second of the proposed extensions, and it seems certain that, unless some further financial provision be made, the extension to include improved maternity services and dental treatment must be postponed to a period even more distant than that contemplated by the Commission.

This is to be regretted, and it emphasizes the regret somewhat widely felt that, in spite of what has become an almost hysterical outcry of "robbery," neither the report of the Royal Commission nor the Economy Bill proposes to utilize for these urgent purposes any portion of the existing enormous surpluses in the books of Approved Societies or a larger proportion of future surpluses. The money is there; it has been contributed by insured persons, their employers, and the State alike; and a modest proportion at least of it is available, and might well be used for these beneficent national health purposes. It is refreshing to find Sir Kingsley Wood, in his official capacity, pointing out that "Approved Societies were extraordinarily prosperous bodies—piling up huge surpluses which were of course partially built up by State contributions," and that "in all probability the amount of the surpluses, especially on the third valuation, would remain undiminished." This new note, from such a quarter, is encouraging to those who still believe that an early improvement in national health administration is possible.

Clause 2 of the Economy Bill, which has yet to be discussed by the House of Commons in Committee, is equally important. It proposes to use the remaining half of the margin of four and a half million pounds mentioned earlier in this article for the purpose of making the whole cost of medical benefit a normal statutory charge on insurance funds, up to a maximum, including administration, of 13s. per insured person entitled to that benefit. At present the permanent statutory charge for these purposes is 10s., and the balance is met by a temporary arrangement expiring at the end of the present calendar year. The Medical Benefit Fund bears the cost of (a) the practitioners' capitation charge, (b) the Drug Fund, including the capitation amount paid to dispensing practitioners, (c) the Mileage Fund, (d) part of the cost of medical referees and of the central index. There is in addition a sum of 6d. per insured person for the administration expenses. The increase proposed on the present statutory amount is therefore 3s. per insured person, and Clause 2 of the bill provides the total sum of 13s. as a whole and as a maximum. It is very important that this sum should be statutorily secured, if only to avoid unseemly wrangles between the Ministry of Health and Approved Societies, with the medical profession as very interested spectators, but it may be doubted whether the maximum amount is really sufficient. The present capitation fee for

practitioners is undoubtedly too low. The amount of work has demonstrably increased, even since the Court of Inquiry awarded the 9s. The call on the Drug Fund has increased considerably of late years, and does not yet appear to have reached its limit. There is a strong case for some additional payment to rural practitioners on account of dispensing costs and time spent in travelling. On present figures alone the margin available within 13s. seems to be very small. Even if the question of the normal capitation fee be not reopened now, it would appear unsafe to stabilize it at the present figure for any considerable period of years; and whether by reason of an expanding call for drugs and appliances, or by reason of a justly augmented payment to medical practitioners, no one can desire a repetition of the legislative situation which arose two years ago. These considerations make the exact form of Clause 2 of the Economy Bill a matter of great interest to the profession.

THE "JOURNAL OF PHYSIOLOGY."

THE number of the *Journal of Physiology* which has just made its appearance is the first issued under the new arrangements rendered necessary by the lamented death of Professor Langley.¹ It is now edited for the Physiological Society by a committee of four, consisting of Sir Charles Sherrington (Oxford, chairman), Dr. E. D. Adrian (Cambridge), Professor A. V. Hill (London), and Professor J. B. Leathes (Sheffield). The new number, which is the first of the sixty-first volume, opens with a memorial notice of Professor Langley by Sir Walter Fletcher, who embodies in his biography of Langley a history of the *Journal*; it is full of detail, yet it may fairly be termed eloquent, and can be read with instruction and pleasure.

The *Journal of Physiology* was founded in 1878 by the late Sir Michael Foster, five years after he went to Cambridge from University College, London. Foster was also the prime mover in the foundation of the Physiological Society, of which the *Journal* has ever since been the organ. Foster was a great and inspiring teacher—he inspired Langley, among others—but he does not seem to have been a very good man of business. Under his editorship the *Journal* was, in 1894, getting increasingly into debt, and was threatened with extinction. Langley in that year arranged to pay off the debt, and thenceforward, until his death last November, he owned and edited it. He took his duties as editor seriously, realizing that if he could make the *Journal* thoroughly good he would be rendering a great service to British physiology, and to physiology all over the world, by placing the work of British physiologists before those of other countries in a suitable manner. He did not limit himself to papers written in this country, but the great majority were British. As Sir Walter Fletcher says: "From the beginning Langley aimed at two ideals. The first was to admit nothing that was either not new or not making some definite advance in knowledge upon the strength of valid evidence adequately presented. The second was to economize space and to save the time of workers everywhere by insisting that each paper admitted should be pruned of every redundancy not needed to satisfy that first condition. . . . His methods were never arbitrary; his judgement of papers was most conscientious and deliberate, based on wide

knowledge of work already published, supplemented at need by that of his colleagues."

Unlike most editors (Sir Walter Fletcher rather unkindly says), for Langley the acceptance of a paper often meant, not the end, but the beginning of a task. "He thought it due to the *Journal* and to science that the paper should be cast in the most effective form and reduced, compatibly with that, to the least size. This meant correction, often heavy correction, commonly suggested in detail by himself, and it involved the exchange of views with sensitive and sometimes irascible authors. . . . With some authors he had difficulties, of course, though it is doubtful whether in any instance his judgement of their failings in this sphere or his proposed remedy for them was shown to be faulty." *Genus irritabile vatum* applies here also, but "if an occasional contributor was vexed the immense majority were well served and grateful, while Langley put the whole body of workers using the *Journal* into his lasting debt. He made, and he now leaves, the *Journal of Physiology* unsurpassed in the high standards maintained both as to the content and as to the form of the papers within it." This, we believe, is a perfectly just estimate, and though much of what appears in our contemporary is over the heads of the majority of us, each of us can turn to its pages with a confident feeling that anything found in it may be trusted to be thoroughly sound within the knowledge of the day. The last volume of the *Journal* contained 478 pages, consisting chiefly of original articles, but embodying brief reports of the proceedings of the Physiological Society. Living and teaching for the whole of his working life in Cambridge, Langley was the central figure of the centre of British physiologists, and his work for the *Journal* helped to make his name perhaps more widely known throughout the world than that of any other British physiologist. But this, of course, was only one side, for he was also recognized by everyone as a master investigator, and all his chief works keep, as they must keep, their place in the significant history of animal physiology.

Appended to the biography is a list of the titles of the published works written by himself or in collaboration with pupils and colleagues. It contains 171 entries; it begins in 1873 with a paper on the physiological action of jaborandi, and runs on to a short paper printed in the last fasciculus of the last volume published during his lifetime. This describes a research into the course of the blood of the renal artery, in which he made use of a method with which he was already familiar—that of injecting the artery with a suspension of rice starch grains and staining sections and slices with iodine. The subject of his first paper is perhaps significant, for though Langley never graduated in medicine, in some of his most important work he used a drug as a key to fit some of the wards of his lock. Langley's contribution to physiology fell into two main parts—those dealing with the mechanism of secretion and those establishing the main anatomical and functional lines of the autonomic nervous system. In the first jaborandi served him well. In the second he found in nicotine as Sir Walter Fletcher says, "a novel and potent instrument, used as he used it, for unravelling the structure and functions of the sympathetic and of the other two parts of the 'visceral' or 'autonomic' system," a problem with which the researches of the last thirty years of his life was largely concerned.

In a contribution which he made to the obituary notice of Langley published in our columns at the time of his death last November Sir Charles Sherrington said: "To work under him or with him was to see

¹ It is published by the Cambridge University Press and can be obtained through any bookseller. The price of the current number is 2s. 6d. The price of recent numbers has varied from 9s. to 13s. The *Journal* is supplied free to members of the Physiological Society.

exemplified a fidelity of observation, a detachment from preconception, and an untiring search for new facts which formed at once a lesson in character and an inspiration for method. . . . He will be remembered as one of the makers of that renaissance of British physiology which was one of the features of the scientific progress of his time."

THE COLONIAL MEDICAL SERVICE.

SOME three months ago certain occurrences in East Africa led the Council of the British Medical Association to take the very grave step of warning members of the profession against accepting appointment to any branch of the Colonial Medical Service recruited in this country. The reasons for this action were detailed in a statement published in the SUPPLEMENT for January 9th (p. 9), and an "Important Notice" covering all such appointments has appeared in the advertisement columns of the BRITISH MEDICAL JOURNAL since that date. The circumstances which necessitated the issue of such a warning may be very briefly recapitulated. A new code of Regulations for the East African Medical Service, dated March, 1925, had been published. These Regulations were welcomed by the Association, both locally and centrally, as marking in many respects the adoption of a progressive and enlightened public health policy in the East African dependencies. They appeared, however, to be open to the grave objection that, without the consent of the officers concerned, and without compensation, they imposed on the existing personnel of the Service certain liabilities quite outside those undertaken on appointment. These liabilities were—first, a general service liability to transfer from one dependency to another in the East African group; secondly, a liability to the prohibition of private practice in any area where the services of independent medical practitioners might be available for the European population; and lastly, a liability to abolition of the allowance in lieu of private practice enjoyed by the holders of certain appointments who were debarred from private practice under existing regulations. The new code in no way safeguarded the rights of existing members of the Service against infringements of the nature indicated. In Zanzibar it was immediately applied in such a manner as summarily to deprive medical officers of a source of income they were actually enjoying at the date of promulgation.

On March 5th the Secretary of State for Dominion Affairs and the Colonies received a deputation from the British Medical Association which made representations on this and other subjects, and after certain supplementary correspondence the Council of the Association is now satisfied that action has been taken by the Colonial Office to safeguard the rights of the officers concerned at every point where they have been threatened under the new regulations. The attitude of the Council in this matter was determined at the outset by its bearing upon the vital issue of the sanctity of service agreements. The action taken by Mr. Amery is, in the view of the Council, a striking vindication of that principle, and accordingly the Important Notice which appeared for the first time in the JOURNAL of January 9th is now removed. It is the more unfortunate that other issues of grave importance to the Services concerned, as indeed to the profession and to the public, should have been raised in the course of conversations between the Colonial Office and the Association, and are still outstanding. Until they are disposed of we cannot

recommend this field of medical practice as offering the prospect of a satisfactory career. The Colonial Medical Service is, in the fullest sense of the word, a key service of the Empire, and we hope to announce the removal of all remaining obstacles to its recruitment before its general efficiency has in any way suffered from the present unsatisfactory state of affairs.

A PRIZE FOR RESEARCH IN DISORDERS INCIDENT TO MATERNITY.

At its meeting this week the Council of the British Medical Association heard from its Chairman, Sir Robert Bolam, of a generous gift of £1,000 to establish a prize for research into the problem of dangers incidental to child-bearing. The donor is Dr. Katherine Harman, wife of the Treasurer of the Association, and it is her wish that the sum should be placed in the hands of the Council, with the suggestion that a prize be awarded once every two years—first, and as a general rule, for the best essay or work on any subject chosen by the Council coming within the definition of "disorders incident to maternity," or secondly, in recognition and encouragement of important work already done or of researches instituted and promising good results. The purpose of this endowment is one in which Mrs. Harman has long taken a deep interest. She has, indeed, a hereditary association with it, for her father, Mr. Arthur Chamberlain, was a founder of the Birmingham Hospital for Women. After graduating in medicine at the University of London, her work as resident medical officer at the Belgrave Hospital for Children, and as inspector under the London County Council, brought her into close touch with the poor mothers of London and the risks to life and health to which they are liable in childbirth. Since her marriage to Mr. Bishop Harman and relinquishment of active medical work, she has kept up her warm interest in the subject of maternity welfare. We need scarcely add that her munificent and practical gift towards an admirable object was gratefully accepted by the Council.

LYING-IN HOSPITALS FOR TUBERCULOUS WOMEN.

THERE are many loopholes in the present system of caring for patients with pulmonary tuberculosis. At one stage or another of their lives, through no fault of their own, they are removed—often with disastrous results—from the supervision of the dispensary or clinic they have been attending. The aim of the tuberculosis officer is to establish a sort of ring—an intimate liaison of dispensary, sanatorium, pre-natal clinic, infant welfare centre, and other institutions—that may facilitate the continuous supervision and treatment of his patients in all circumstances. In no other country is this aim pursued more actively than in France. Recently Dr. Couvelaire¹ has given an account of the method he has employed during the last few years in dealing with pregnant women suffering from open tuberculosis. At the Baudelocque lying-in hospital in Paris a special pavilion has been set aside for these patients, who are transferred there on the recommendation of the officer in charge of the tuberculosis clinic. During the whole of their lying-in period they continue to be under treatment, special arrangements being made for patients who have an artificial pneumothorax. At some time during pregnancy they are given to understand that their children must be taken from them at birth and brought up by other hands, lest they too should be infected. These children are first cared for in a special block of the hospital, well separated from the tuberculosis pavilion, and later are sent to the country so that their childhood may be spent in non-tuberculous surroundings. During the four years following November, 1921, when this scheme was inaugurated, 231

¹ Bull. de l'Acad. de Méd., March 2nd, 1926, p. 196.

patients were admitted to the hospital. Dealing only with the first 101 patients, about whom accurate information is available, we find that 15 died within the three months following delivery, and 23 more within the first year, bringing the mortality during this period to 37.6 per cent. As regards the babies, of the first 213 that were born 46 died within the first four months. How many died later is not recorded, but even if we assume that no further deaths occurred the mortality rate for the first year was 216 per 1,000 births. Only one or two of these appear to have been due to accidental contamination with tuberculosis; most were the result of unsuccessful feeding. These figures are not calculated to inspire confidence in the scheme as it is now worked. While admitting that a high mortality amongst the tuberculous mothers is inevitable even under the best conditions, we are disposed to think that the infantile mortality rate is greater than it need be. The main trouble has been in their feeding; too many died—almost wilfully, as one is impatiently inclined to exclaim—of simple malnutrition. But there is evidence now to suggest that this trouble will be surmounted. In any case it is clear that the scheme is based on the right lines; its success will probably be a matter of time and experience.

CARDIAC ARRHYTHMIA IN CHILDHOOD.

At a recent meeting of the James Mackenzie Institute for Clinical Research, St. Andrews, Dr. Paton gave an address on the mechanism responsible for the irregularity of the youthful heart. He began by referring to the guarded nature of the views expressed by Mackenzie on the matter in the fourth edition of his *Diseases of the Heart*. However simple an explanation of the phenomena may seem to some people, it was obvious that to Mackenzie's mind no satisfactory hypothesis had been formulated. He believed that both sympathetic and vagus impulses played a part in producing the arrhythmia, and concluded that the source of the impulses is probably to be found in the activity of the respiratory muscles or some other peripheral source. He believed that the disappearance of the irregularity in febrile conditions was due to the action of toxins of microbic origin on the sino-auricular node, resulting in such an increase of rate that the irregularity is abolished. Dr. Paton referred to impulses from within the heart itself and to the variations in carbonic acid content of the blood during respiration as possible causes of sinus arrhythmia, but stated that the clinical evidence he had been able to collect indicated that the irregularity had its origin in the activity of extracardiac reflex arcs, of which the cardiac fibres of the vagus and sympathetic cause the effector response. The problem then could be stated simply: Where in health do the impulses determining the activity of these nerves originate, and at what points are the reflex arcs interfered with in disease? Tracings were shown illustrating the irregularity and its experimental modification by deep breathing, holding the breath, etc. While admitting that no certain conclusion could be reached, Dr. Paton advanced evidence which suggested that the impulses hastening the rate in inspiration were probably circulatory in origin, the variations of the pulmonary capillaries in response to variation in intrathoracic pressure being a probable source of these. The vagal stimuli which induced slowing in expiration probably originated in the variations of pressure or circulation in the abdomen. No pulmonary condition is known which induces slowing of the heart. He looked upon the variation in rate as an attempt at adjustment to the changes in distribution of blood as between the pulmonary and systemic circulations, resulting from the variations in the capacity of the chest. Charts were exhibited which proved that disappearance of the irregularity in disease could be independent of a rise of temperature or of pulse rate, and that the irregularity

may persist in spite of a high pulse rate. The subject was difficult because the opposing action of the two cardiac nerves made it impossible to differentiate the effect due to each.

CRYSTALLINE INSULIN.

PROFESSOR J. J. ABEL, the veteran professor of pharmacology in Johns Hopkins University, publishes in the *Proceedings of the National Academy of Sciences* (vol. 12, No. 2, February, 1926) a preliminary account of the preparation of crystalline insulin. Professor Abel had already published last year¹ a simple method for the preparation of highly concentrated insulin with a rabbit unitage of 40 to the milligram. The present paper takes us a step further; the fraction IV of the previous paper is dissolved in acetic acid and precipitated by a solution of brucine. The clear centrifugate contains the bulk of the insulin, which is precipitated by pyridine, and insulin crystallizes out. The crystals are crystin-like in shape, and, like crystin, contain sulphur; 1/100 milligram of the crystals per kilogram administered to rabbits lowers blood sugar to about the convulsant level—0.045 per cent. In this substance we have a type of catalyst which, in these very dilute solutions, influences carbohydrate metabolism in this remarkable manner. We desire to offer our congratulations to Professor Abel and his colleagues on the completion of this brilliant investigation, which promises to open up a new insight into carbohydrate metabolism.

THE RELATION OF TRAUMA TO CANCER.

THE question of the relationship between malignant disease and trauma has been changed from an academic into a practical problem owing to the fact that so many employees claim compensation for some variety of malignant disease whose origin they trace to an antecedent trauma received whilst at work. In the future surgeons and pathologists are likely to be called upon for evidence on this question more and more when these cases come to litigation or arbitration. Hospital patients are often anxious to trace their disease to some remembered event, and perhaps the medical profession is at fault for having accepted, or allowed to pass uncontradicted, the opinion that a sarcoma has, for instance, been etiologically related to a fracture. In a recent paper on this subject² Drs. H. Mock and J. Ellis² report the results of an inquiry into the histories of 300 cases of cancer; their conclusion is that a traumatic origin was too often assumed on inadequate evidence. For application to cases that have a definitely legal aspect and appear before courts and compensation boards for adjustment, arbitration, or litigation, they suggest the following postulates: (1) Reasonable proof of a trauma of sufficient seriousness to cause definite tissue changes. (2) The developing neoplasm must be at the same site as the original injury, and must involve some of the tissue which, without reasonable doubt, could have been involved in the original trauma. (3) Definite evidence must be produced to prove that no neoplasm existed at the site of injury prior to the accident. (4) In addition to the history of trauma there must be a history of definite bridging signs, such as a persistent swelling, an unhealed wound, or anatomical and functional disturbances which connect the trauma with the malignant growth. (5) The time that has elapsed between a given trauma and the development of the malignant tumour need not be considered if the foregoing conditions have been present. The authors think it is safe to say that a malignant tumour that develops within two weeks after the trauma existed prior to the injury; on this point, how-

¹ *Journal of Pharmacology*, 25, 423, 1925; and *Science*, 67, 169, 1925.

² *Journ. Amer. Med. Assoc.*, January 23rd, 1926, p. 257.

ever, some pathologists would disagree with them, for there have been a considerable number of cases in which a tumour appeared almost immediately after the application of a carcinogenic agent. (6) Where a pre-existent malignant tumour has been aggravated or accelerated in its growth by a trauma the employer or his insurance company should be held responsible provided aggravation could be shown, and be required to pay for the permanent disability that might follow, but he should not be held responsible for the subsequent death of the patient due to malignancy, for the trauma could not aggravate to the point of fatality a pre-existent condition which had already doomed the patient; nor should he be held responsible for hastening the death, for this could only be speculation on the part of the medical advisers. (7) In the case of a metastatic or secondary tumour developing at the site of a trauma the first four postulates should be met before the employer is held responsible, and such responsibility should be limited to the treatment of the local condition; it should not be extended to include responsibility for the death that is bound to occur shortly, as the trauma could not have aggravated the primary growth. At the close of their paper the authors give the histories of nine cases which seemed to fulfil their postulates, thereby placing them in the class of malignancy related to trauma, and hence entitled to compensation.

PREVENTION OF TUBERCULOSIS IN NEW YORK.

WHEN Trudeau laid the foundation of antituberculosis work in America by demonstrating the curative value of the open-air life, attention was at first entirely directed to treatment, and prevention followed only as an afterthought. Mr. G. J. Drolet, a statistician in the research service of the New York Tuberculosis Association, published last year in the *American Review of Tuberculosis* a careful survey of the mortality from tuberculosis in the city of New York during the previous quarter of a century. Whereas in 1898 in rather over one million children 1,370 deaths were registered as due to various forms of tuberculosis, in 1923 they numbered only 547, though the population had increased by more than 675,000. Tuberculous meningitis had been correspondingly reduced in the same period, the death rate dropping from 78 to 17 per 100,000 children. The abdominal type of tuberculosis in children under 15, though apparently of a less fatal character in New York than in Great Britain, has also shown a very marked decline. Until lately the death rate from tuberculous peritonitis often reached 7 or 8 per 100,000, whereas in the last two years it dropped to 1, a decrease ascribed to the active work of the health authorities of the city, particularly in the complete pasteurization of all milk except the certified, and in establishing the annual examination of about 100,000 persons concerned in the handling of food. The decline in tuberculosis is shown statistically to have been much greater in children than in adults. Whereas in 1898 the death rate for children under 15 was 15 per cent. of the total tuberculosis death rate, in 1923 the percentage dropped to 9.6. During the quarter of a century the adult death rate decreased by 35 per cent., but the rate for children under 15 by 60 per cent., although the population of the city doubled itself during that time. Comparing New York with the total united rural and urban areas of the United States it was found that, whereas in 1900 the death rate from tuberculosis among children under 15 in the registration area was 64 per 100,000, in New York City it was 130, or more than twice as high. In 1921 the death rate in that age group in the United States area had been reduced to 28, and in New York City to 35. This great decline in tuberculosis in children occurred in three main periods. Between 1898

and 1905 the first great drop occurred, when the rate fell from 136 to 91 per 100,000; between 1905 and 1911 an almost stationary period followed, but from 1911 to 1916 the rate fell again from 95 to 66. After another stationary period, which included the influenza epidemics of 1917 and 1918, a third decline occurred, and between 1919 and 1923 the rate fell from 71 to 33. The prime factor in this fall is believed to be the segregation of advanced cases. During the level period between 1906 and 1913 no new tuberculosis institution was added to the resources of New York City. In 1913, however, a large municipal hospital for 765 beds was opened, and this was immediately followed by a sharp drop in the meningitis death rate. In 1914 another hospital with 200 beds was established, and in the same year pasteurization of milk became the rule in the city; the tuberculosis death rate from other than pulmonary forms of the disease was halved very soon afterwards. Clear evidence is thus given of the value of protecting children from infection with tuberculosis at a time when their bodies are not fully developed. In consequence of propaganda work and the improved educational surroundings the children are, moreover, enabled to build up their resistance to disease, and have now a much greater opportunity of reaching adult life without being endangered by tuberculosis.

HELIO THERAPY IN RICKETS.

DR. H. STANLEY BANKS, medical officer of health for the burgh of Motherwell and Wishaw, has made a preliminary report of a survey of cases of rickets detected at the child welfare consultations since the beginning of 1924. He found that the age period in which the disease could be most unhesitatingly diagnosed on clinical grounds was from 6 months to 3 years, and that 60 per cent. of the children of this age brought to a child welfare centre in his industrial district during two years were clinically recognizable as suffering from rickets. Making allowance for the special process of selection involved, he estimates that not less than 30 to 40 per cent. of the children of this burgh pass through a stage of active rickets. Before the artificial sunlight clinic was started in the borough, treatment by cod-liver oil was employed, with poor results on the whole as regards rapidity of calcification of the bones and the improvement of general health. Dr. Banks records a series of 75 cases in which not fewer than twenty exposures to artificial sunlight were given, and another series of 43 which have completed a shorter course. In addition 100 other patients are at present under treatment. He found that after only three or four exposures marked improvement occurred in the general condition, and that the increased muscle tone enabled children to walk who had previously been unable to do so. Two 25-ampere carbon arc lights were used, together with two mercury vapour lamps; the initial exposures were fifteen minutes of the carbon arc, together with one to three minutes of the mercury vapour lamp. The exposures were rapidly increased up to about thirty minutes of the carbon arc lamp and ten minutes of the mercury vapour lamp, the children moving about so as to secure this proportion of the two sources of ultra-violet light. Baths were given after the exposures, and were found to have a tonic as well as a cleansing value. Three exposures were given each week for the first month, after which two exposures a week were often found sufficient. Dr. Banks states that if the course of treatment ends in winter or early spring, and especially if the home conditions are very bad, the improvement in the child's health may not be maintained, and that after a month or two a further but shorter course of treatment is required. This relapse in general health has not, however, been found associated with any clear evidence of decalcification of the growing ends of the bones, though

the muscles became toneless and flabby again. In the vast majority of cases, however, the improvement in general health was well maintained. Radiograms of the radius and ulna, or of the tibia and fibula, were made in most cases at the beginning and at the end of the course, and in special cases at intervals during it. The x rays were found especially useful in determining whether the rickets was in an active or a healed condition. In gauging the results of treatment attention was paid to the radiographical evidence of calcification in bone; improvements in bony deformities, general health, and muscular tone; increase or decrease of weight; and rise in the haemoglobin content of the blood. The radiographical evidence included healing of the typical rachitic lesions at the ends of the long bones, the formation of a dense and regular provisional zone of calcification; an increase of calcification under the periosteum; dense calcification around greenstick fractures; and straightening of curvatures by new lines of calcification laid down in the lines of greatest stress according to Wolff's law. Up to the age of $2\frac{1}{2}$ years bony curvatures became appreciably more straight, and the child was able to walk and run actively; after the age of $2\frac{1}{2}$ curvatures of the lower limbs did not completely disappear. The improvement in muscular tone was very marked in most cases. The average monthly gain in weight of thirty-three cases between the ages of 1 and 2 years was 12.8 ounces, as compared with the average normal gain of between 6 and 7. Dr. Banks points out that this is the more remarkable since children with relaxed abdominal walls and flabby musculature lose weight in the first few weeks of the course, as the muscles begin to gain tone. In eleven completed cases in which monthly examinations of the haemoglobin in the blood were made, an average increase during the course was reported of 6.3 per cent.

THE BRITISH ASSOCIATION.

THE PRINCE OF WALES, who is to preside over the meeting of the British Association at Oxford next August, will deliver his address on the evening of Wednesday, August 4th. In it he is expected to deal *inter alia* with the relations between scientific research, the community, and the State, both at home and in the oversea Dominions. The address will be given in the Sheldonian Theatre at 8.30 p.m.; it will be relayed to the Town Hall and to the hall of the Oxford Union Society, and will probably be broadcasted generally. This is the ninety-sixth meeting of the association, and the fifth to be held in Oxford. The first took place in 1832, when Professor William Buckland (afterwards Dean of Westminster) was president. At the second meeting, which took place in 1847, the president was Sir Robert Inglis, then M.P. for the University. It was at this meeting that Joule first really impressed upon his colleagues the value of his theories as to the mechanical equivalent of heat. At the third meeting, in 1860, the president was Lord Wrottesley, who had already occupied the chair of the Royal Society and of the Royal Astronomical Society. Among the discussions at this meeting was that in which Huxley and Hooker became involved in the famous controversy with Wilberforce over the Darwinian theory. At the next meeting, in 1894, the president was the Marquess of Salisbury, whose address, with Huxley's reply, revealed that the same controversy, though in modified form, was still alive. Among the announcements made at this meeting was that of the discovery of a new system of hieroglyphics and a pre-Phoenician script from Crete and the Peloponnese, by Sir Arthur Evans, while Sir Oliver Lodge, in illustrating the reception of Morse signals by the deflections of a Thomson marine-signalling galvanometer over a distance of some hundred yards, gave the first public demonstration of "wireless" telegraphy. This year's

meeting will have thirteen sections, which will be at work in the mornings, and in some instances in the afternoons, on Thursday and Friday, August 5th and 6th, and on the first two days of the following week. The concluding general meeting will be held on Wednesday, August 11th. The president of the Section of Physiology is Professor J. B. Leathes, F.R.S., of Sheffield, whose presidential address on function and design will be delivered on the morning of Thursday, August 5th. At noon on Tuesday, August 10th, Dr. J. S. Haldane, F.R.S., will give a lecture on acclimatization to high altitudes. On Friday, August 6th, the section will hold a joint meeting with the Section of Zoology for the discussion on the value of tissue culture in biology. Receptions will be held on the evening of August 6th by the Vice-Chancellor of the University and the Mayor of Oxford, and a *conversazione* by the Local Executive Committee, with the co-operation of the Junior Scientific Club, will be held on August 10th in the Ashmolean and University Museums. On Saturday, August 7th, excursions have been arranged to Stratford-on-Avon, Warwick, and Kenilworth, to the Cotswolds, on the River Thames, and to Reading University. Special morning services will be held on Sunday, and the preachers will be the Bishop of Oxford, the Master of the Temple, the Bishop of Winchester, the Dean of St. Paul's, and the Rev. W. B. Selbie, D.D. (Principal of Mansfield College). Copies of the preliminary programme can be obtained from the secretary of the British Association, Burlington House, London, W.1.

ANNUAL MEETING OF THE AMERICAN MEDICAL ASSOCIATION.

THE seventy-seventh annual meeting of the American Medical Association will be held in Dallas, Texas, from April 19th to 23rd; the House of Delegates, which is the ultimate governing body of the association, will meet at the same time. The delegates are elected annually by the State medical associations, the army, navy, and public health departments, and by the scientific sections of the American Medical Association—namely: general and abdominal surgery; ophthalmology; diseases of children; pharmacology and therapeutics; nervous and mental diseases; dermatology and syphilology; gastro-enterology and proctology; radiology; the practice of medicine; obstetrics, gynaecology, and abdominal surgery; laryngology, otology, and rhinology; pathology and physiology; urology; orthopaedic surgery; and preventive and industrial medicine and public health. In connexion with the annual meeting many scientific exhibits are being prepared. An immunology exhibit will illustrate the practical applications of this subject, and include the demonstration of the use of toxins, antitoxins, vaccines, allergins, and similar preparations. For the morbid anatomy exhibition fresh pathological material will be received daily from various hospitals in the larger cities of Texas, augmenting the local supply. A demonstration of fractures will include a series of Colles's fracture, the hyperextension of chauffeur's fracture of the radial styloid process, Pott's fracture, and fracture of the tibia and fibula above the joint. Dr. Aldo Castellani is preparing a demonstration of the technique of isolating and staining mycological preparations in the case of some tropical mycoses. A series of photographs and preparations will illustrate the varying clinical appearances of cancer, particularly of the skin, with special reference to differential diagnosis. In another section the results of cancer research will be illustrated. The demonstration arranged by the Mayo Clinic will include carcinoma of the stomach, foreign bodies removed from the air and food passages, and specimens to illustrate circulation in the liver in health and disease.

Nova et Vetera.

ANTIMONYALL CUPPS:

POCULA EMETICA, OR CALICES VOMITORII.*

BY

SIR ST. CLAIR THOMSON, M.D.,

PRESIDENT OF THE ROYAL SOCIETY OF MEDICINE.

"ANTIMONYALL CUPPS"—Pocula Emetica, or Calices Vomitorii—are rarely met with nowadays. There is one in the possession of the Royal College of Physicians. It was presented to the College in 1824 by a Mr. Gurney, who had married a Miss Palmer, who was a descendant of the Dr. Baldwin Hamsey to whom it originally belonged. The short story of it, compiled by Dr. Monk, states that it was bought in Gunpowder Alley, at the sign of the Magpie, in 1637, for 50 shillings, and that three cases of death were said to have been caused by the vomiting resulting from drinking wine which had stood in these cups. There is also such a cup in the Museum of Practical Geology in Jermyn Street. It bears on one side, on a shield surmounted by a coronet, the following inscription in German: "Du bist ein Wunder der Natur und aller Menschen sichere Cur."† The Pharmaceutical Society does not possess a specimen; nor is there one in the admirable Wellcome Museum in Wigmore Street, although it is the largest and most complete collection in the world of objects illustrating the history of medicine.

Two Examples.

Hence I considered myself very fortunate when the opportunity came my way to exhibit two perfect specimens before the Section of History of Medicine. The record of these two particular "Antimonyall Cupps" is brief and inadequate. For the loan of them I am indebted to my old friend Mr. A. de Navarro, a well known connoisseur in art.

Amongst other things he collects pewter, on which he has written an interesting book, and he is at present President of the Pewter Society. It was in this connexion that he secured, through a well known silversmith in Old Bond Street, as an addition to his collection of pewter, the two cups you see before you. Pewter is an alloy of tin and lead, but there are varieties. For instance, "plate pewter" consists of 89 per cent. tin and 7 per cent. antimony, fused with 2 per cent. bismuth and copper. It takes a fine polish. "Triple pewter" contains less tin and more antimony (15 per cent.). It is used in such minor articles as toys and syringes. "Lay pewter," used for inkstands, is composed of 80 per cent. tin and 20 per cent. lead. Hence some pewters contain no antimony, and none more than 15 per cent. Each of these cups is in an old leather case beautifully tooled, and when, inside each case, Mr. de Navarro noticed a label with the words "Antimonyall Cupp" he very kindly brought them to my notice and has lent them for your inspection. The spelling and calligraphy are of the seventeenth century, as is also the leather case—possibly of Italian workmanship (see figure).

You will notice that these cups must have had considerable use, if we may judge from the well worn mark on the case, made by the thumb in opening and closing it. Each cup holds between 3 and 4 ounces of liquid.

Emesis.

Emesis, or vomiting, is a therapeutic measure of wide and ancient use. Although nowadays chiefly employed by

dogs and cats to "cleanse the stuff'd bosom of that perilous stuff which weighs upon the heart," it was a relief which most of us had recourse to, involuntarily, in the days when we were mewling and puking in the nurse's arms. With increasing years we employ it more rarely, and chiefly during a cross-Channel journey as a preparative for, or a corrective after, a week-end in Paris.

It was not so in classical times. Seneca writes that, in the reign of Nero, many "vomited to eat and ate to vomit." Cæsar, who was a temperate man, took an emetic after a heavy meal with Cicero, who mentions it without disapproval. Vitellius the glutton and Claudius habitually used emetics. But, in spite of these records, there are some students of the Roman age who say that daily vomits were not common in wider circles. The ancient Egyptians, according to Herodotus, were the healthiest of mankind and three days in every month they used emetics and enemas. Hippocrates recommended regular vomitings and purgings. Asclepiades condemned them. Celsus disapproved of them as an aid to gluttony, but agreed that, as an occasional resource, they were conducive to health. Galen prescribed them before rather than after meals. Pliny and Plutarch only advised emetics in actual disease.

Antimony.

To turn now to the metal of which these cups are made, we might recall that antimony was known to the ancients as "stibium," "barbason," or "alabastrum."

As to its history, I wish time allowed me to make use of all the erudition and references so kindly placed at my disposal by our learned Fellow, Dr. Charles Singer. He tells me that the mediæval Latin word "Antimonium" was first used by Constantine, the African, who died in 1087. This Arab left North Africa for Salerno about 1070, became a monk, and translated medical works from Arabic into Latin. In one of these, the *Liber de Gradibus* (or Book of Degrees), the action of

drugs is classified into four degrees, and antimony comes in the fourth or highest degree.

Many virtues were claimed for it and its derivatives. Ladies will be interested to hear that it was used in ancient times to beautify the eyebrows and give a dilated look to the eyes. Omphale, the Lydian queen who captivated Hercules, used "stimmi" for the purposes of the toilet; and it was possibly with a preparation of antimony that Jezebel "painted her face and tired her head" (2 Kings ix, 30). Anyhow, the "kohl" still used by females in Egypt and Persia is prepared from antimony.

As a remedy antimony owes its chief advance in medicine to the recommendation of Paracelsus (1480-1541), but it attracted little attention until the early part of the seventeenth century, when it was made popular by the enthusiastic writing of Basil Valentine, a monk of the Order of St. Benedict, who published at Leipzig in 1604, and in German, a work entitled "Triumph Wagen Antimonii," translated into English in 1678 under the title of "The Triumphant Chariot of Antimony." The author included antimony amongst the seven wonders of the world and ascribed to it extraordinary virtues.

A vast literature has arisen round this Basil Valentine, but I have the authority of Dr. Singer to state that Basil Valentine the monk never existed, and that the book of which he is the reputed author was written by a certain Johann Thölde, of Hesse, a chemist and salt manufacturer. This astute chemist added to the interest and mystery by saying he had, with great labour, translated the monk's work from Latin into German. Anyhow, the work was translated into many languages, and the boom

Two seventeenth century "Antimonyall Cupps," one in its leather case.

* Read before the History of Medicine Section, Royal Society of Medicine, March 17th, 1926.

† A. C. Woolton: *Chronicle of Pharmacy*, London, 1910, vol. i, p. 365.

in antimony was launched and in full swing through the seventeenth century. Charles de Lorme appears to have made a huge practice and much renown by prescribing it to Henry IV, Louis XIII, Cardinal Mazarin, and Madame Sévigné. He claimed for it that "qui plus en boira, plus il vivra"! and it is true that amongst his patients were Guez de Balzac who died at 70, Boileau who died at 75, and Daniel Huet who reached the age of 91, while he himself nearly became a centenarian.

As a striking example of this fulsome laudation by an unqualified practitioner I can recommend the perusal of a pamphlet published in London in 1642 by "John Evans, Minister and Preacher of God's Word, dwelling near the Golden Lyon in Fetter Lane." Its title is:

"The Universal Medicine, or the Virtues of my Magnetical or Antimoniall Cup. Confirmed to be an health-procuring, health-preserving, and an health-restoring Effectuall Medicine.

By extant Monuments of Antiquity.

By testimonies of Honorable Personages.

By 100 admirable and rare experiments.

By 200 Persons of quality that have experienced the same."

I am sorry the Royal Society of Medicine does not possess a copy of this egregious pamphlet, but it can be seen in the Library of the Royal College of Physicians. Mr. Barlow, the Bedell, has kindly called my attention to it, pointing out how the testimonials from the "persons of quality" closely resemble those issued by quack-medicine vendors in our own day. The reverend author, who repeatedly protests that he is ready to "answer before God and Man" in regard to the "Mystical and Celestiall" qualities of his vinum antimonialis, was not free from personal interest in making "a Compendious declaration of the most admirable Virtues of the Magnetical or Antimoniall Cup," for he adds that it was "compounded and made of the Philosophical composition, which is of my own proper and peculiar Invention and Preparation."

The Rev. John Evans cited "ancient Philosophers and learned Physicians" who had "writton of the Medicinall vertues of this Magnetical or Antimoniall Cup," beginning with Theophrastus Paracelsus and including Basilius Valentinus. This did him no harm, as Paracelsus was dead and Basilius Valentinus had never existed. But, unfortunately, he added that "Sir Theodore Mayerne, Kt., and Dr. of Physick, and Physician in Ordinary to the King's most excellent Majesty, hath approved and experienced the same oftentimes with happy and good success."

Now Turquet de Mayerne was a French (or possibly a Swiss) physician who had been "struck of the register" by the Faculty of Medicine of Paris in 1603, simply because he was a supporter of antimony, and even although he was the favourite physician of Henry IV. He settled in London, was appointed Physician to James I, became a Fellow of the Royal College of Physicians, and it has been suggested that he is portrayed by Shakespeare as "Dr. Caius" in the *Merry Wives of Windsor*. If so, it must have been a caricature, for his behaviour in regard to this unauthorized use of his name, in an advertising pamphlet by the Reverend John Evans, was very different from what one would expect from such a figure of fun as the physician in the *Merry Wives of Windsor*. De Mayerne promptly took action. There is a book written by Dr. Charles Goodall in 1684, on "The Royal College of Physicians of London," with "an Historical Account of the College's proceedings against Empiricks and unlicensed Practisers in every Princes Reign from their first Incorporation to the Murther of the Royal Martyr, King Charles the First." Well, on page 442 of this book, and under the date of "24 Martii 1634," we read the following Minute:

"Mr. President desired that diligent search be made after the sellers of purging Diet-Ales and such Comfit-makers as sold purging confections. Dr. Mayerne wrote a Letter to Mr. President complaining of Mr. Evans a Minister who had abused his name about his Antimoniall Cup; upon which 4 Fellows of the College were sent to the Archbishop of Canterbury to acquaint his Grace therewith, and with the import of Sir Theodore Mayerne's Letter. After this Evans was brought before the High Commission, where the Archbishop asked him for his Orders, which he had not then present. He then caused him to be sworn to answer to such Articles as should be objected against him. His Grace was

highly displeased at the printing of his Book, of which all that could be found were taken away. The College Beadles was to help to find out more, that they might be destroyed. Sir Nathanael Kitch died of a Vomit made by this Antimoniall Cup. The Lady Amyc Blunt died by the Same Medicine in Charter-house yard. Another case of the same kind was reported by Dr. Harvey."

The precious pamphlet of Mr. John Evans must have been largely responsible for producing in 1651 (just nine years later) a counter-blast from "James Primrose, Doctor in Physick." This "learned physician" had the courage to attempt the Sisyphean task of exposing "Popular Errors, or the Errors of the People in Physick: Profitable and necessary to be read by all. To which is added by the same Author his verdict concerning the Antimoniall Cuppe."

This delightful little book can be read in our library. It gives some shrewd knocks to the Rev. John Evans in the last chapter, where Dr. Primrose writes:

"Not that I doe altogether dislike the use of Antimonie, for I have often used it with good successe, but better prepared. But especially the founder of the Cup is to be blamed, for selling such a cheap medecine at so deare a rate, the right use whereof hee doth neither teach the people, nor I think he himself knowes."

That Evans is here referred to is clear from the next paragraph, where Dr. Primrose ironically says:

"As for the Founder of the Cup, he professes himself a Minister, and Preacher of God's Word, that is, a man that will scorn to deceive anybody and will not meddle beyond his knowledge."

The courage of Dr. Primrose is to be admired. It must have helped to the undoing of that unctuous humbug the Rev. John Evans. We may also congratulate Sir Théodore Turquet de Mayerne and the Royal College of Physicians on their successful action. The leaders and guardian bodies of the profession in those days appear to have been more successful than we are in their suppression of self-seeking frauds.

The controversy about antimony raged in Paris for over a century, dividing the profession into two camps—the antimonialists and the anti-antimonialists—causing, according to the habits of the times, the bitterest personal animosities and recriminations. It is referred to by Molière in *Le médecin malgré lui*. The rogue in the drug—fostered by writings like Basil Valentine's "Triumphal Chariot of Antimony," and Evans's "The Universal Medicine"—led to such popular recklessness in its use that the Faculté was possibly justified in declaring it a poison and reprehending its administration. In 1609 another eminent physician, Paulmier, was expelled from the Faculté for having administered antimony. This prohibition, confirmed by a solemn Act of Parliament in 1666, brought forth calmer judgements, like those of Dr. Primrose, and, possibly, confidence in the merits of the remedy was partially restored by the alleged cure of Louis XIV by tartar emetic for a dangerous illness in 1657. Anyhow, in 1666—just a century after its prohibition—another equally solemn Act rehabilitated the reputation of the metal.

Possible Origin of these Cups.

I wonder if the prohibition of antimony during a whole century had anything to do with the origin of Pocola Emetica, Calices Vomitorii, or Antimoniall Cupps? The use and sale of the drug were interdicted by law, and knowing human nature as we do, and realizing how the banning of any man or his methods at once makes a hero of him and a panacea of his nostrum, it is possible that these cups came into being in that way. Wine being allowed to stand for some time in one of them became impregnated with tartrate of antimony, from the action of the tartar contained in the wine upon the metal of the film of oxide formed upon its surface. Now, as the prescribing and selling of antimony was forbidden, these cups effectually set legislation at defiance, added the spice of a forbidden drink to the virtues of the draught, saved the apothecary's bill, and must have appealed to imaginative patients as an agreeable—being alcoholic—mode of administration! The cup, too, could be handed down from generation to generation, gathering increased powers of suggestion with the years.

It is said that these cups were common in monasteries, and those monks who took too much wine were punished

next morning by having to drink some more which had been standing in a poculum emeticum.

An Ancient Recipe for Antimonial Wine.

I might explain that what in those ancient days was called "Regulus of antimony" is what we call metallic antimony, to distinguish it from crude antimony. Now, in Pomet's *Compleat History of Drugs*, of which the English translator says in the third edition of 1737 that it is "a work of great Use and Curiosity," we note, amongst much quaint lore, the following reference to *Pocula Emetica* on page 360:

"Of this *Regulus* is prepar'd the purging or rather the emetick wine: And here you ought to be caution'd to throw away the three or four first wines you make with the Cups, lest they should produce some ill Accident. Whereas most People who have Occasion for the Gobelets or Cups of the *Regulus* find difficulty to come by them, let them apply to a Founder, and they will have what Sorts and Sizes they will, at a cheap Rate, without troubling themselves with Moulds, as several have done to their Labour and Cost, who have at last been oblig'd to give over the Attempt, not being able to make one Cup without a Hole or some other Defect. You may also get these same Founders to make you the perpetual Pills, or you may easily make them yourself with a Musket Ball Mould."

Perpetual Pills.—"The Pills serve for those that have the Twisting of the Guts, or *Miscere me*, so call'd. When they are returned from out of the Body, 'tis but washing and cleansing of them again, and they'll serve as oft as you please; which gives them the Name of Perpetual. They may also be infus'd, as well as the *Regulus* in Wine, cold, for the Space of twelve Hours; which is said to be a good Medicine for strong Constitutions."

Origin of the Word "Antimony."

The original work of the German monk Basil Valentino was published in Latin under the title of "*Currus Antimonii Triumphalis*," and his name, of course, was Latinized into *Basilus Valentinus*. It is to his scientific investigations with this mineral and its products, carried out in a thoroughly scientific and Teutonic fashion, that we owe the ridiculous story as to the origin of the name of Antimoine or Antimony (against monks). The origin of this title is described in Pomet's work in the following words:

"It acquir'd the Name of Antimony, according to the Opinion of some, from a German monk, the aforesaid *Valentine*, who in Search after the Philosopher's stone, was wont to make much Use of it for the more ready fluxing his Metals, and throwing a Parcel of it to some Swine, he observ'd that they had eaten it, and were thereby purged very violently, but afterwards grew the fatter upon it; which made him harbour an Opinion, that the same sort of Cathartick, exhibited to those of his own Fraternity, might do them much Service: but his Experiment succeeded so ill, that everyone who took of it died. This therefore was the Reason of this Mineral being call'd *Antimony*, as being destructive of the Monks."

Chemical Composition of the Cup.

For the definite proof that these cups are actually made of antimony I am indebted to the kindness of Sir Herbert Jackson, K.B.E., formerly Professor of Chemistry in King's College and now Director of the British Scientific Instruments Research Association. A very small quantity of material, scraped from the bottom of one cup, was sufficient for him to apply tests which prove that the cup is made almost entirely of commercial antimony. There can only be, he reports, very small quantities of tin and lead. The cup is a good specimen of metallic antimony. The metal is fairly hard and brittle, just as antimony is.

Their Power of Producing Antimonial Wine.

Finally, to settle the question whether the antimony of which these two cups are made could be dissolved out into wine allowed to stand in them, I again had recourse to the learning and kindness of Sir Herbert Jackson; his report is as follows:

"The white wine which has stood in the antimonial cup for seventeen hours contains a notable amount of antimony. No quantitative determination of the amount has been made, but, looking at the antimony separated from the wine, a rough estimate would be that there is about half a grain of antimony, expressed as antimony oxide, to the ounce of wine. I lay no stress on the quantity, but what I know you were anxious to learn is whether a wine of such character standing in the antimonial cup would dissolve an appreciable amount of antimony; it clearly does."

As I have noted, each cup holds 3 to 4 ounces, so that the wine would contain a dose of $1\frac{1}{2}$ to 2 grains of antimony.

Conclusion.

In one of these cups I have had some white wine standing for exactly twenty-four hours. If anyone would like to quaff it he is very welcome to do so at his own peril. You will notice how it has removed the polish from the inside of the cup.

Having now proved the potency of these antimonyall porringers, we might refer the question to the Section of Therapeutics as to whether their use should not be revived in these days of intestinal stasis? If approved of, they might, particularly if combined with the "Perpetual Pills," become popular, especially nowadays when economy and thrift are so much called for. Only our pharmaceutical friends and the manufacturers of paraffin emulsion might deplore such a revival.

In conclusion, I apologize for butting into a Section so learned as this with a communication so trivial. My excuses are based on the kindness of my friends—Mr. de Navarro, who has entrusted me with these two unique specimens of *Pocula Emetica*; Dr. Singer, who has furnished me with so much lore on the matter; and Sir Herbert Jackson, whose modern scientific investigations have enabled us to verify the empiric practice of three hundred years ago.

THE MAUDSLEY HOSPITAL.

SECOND ANNUAL REPORT.

THE two main purposes of the Maudsley Hospital are the early treatment of mental disorder and research into its causation. As remarked by Dr. Edward Mapother, the medical superintendent, in his first annual report, these aims are not coincident, but are not necessarily mutually exclusive. Cases are accepted often because of the unique opportunities they present for the study of their causation, quite apart from their chances of recovery. The methods adopted for the realization of the aims of the hospital were put to the test during the first year, and were fully discussed in the first annual report. Dr. Mapother tells us that no change of any material kind, and no reversal of any item of policy, has been found necessary as the result of further experience.

The steadily increasing pressure on the hospital furnishes the best proof of how great is the demand for a hospital of this type. The total number of patients treated during the second year was 1,304, and the number of in-patients 590; the corresponding figures for the first year were 1,012 and 452. A graphic record of the admissions showed a marked predominance of applications from districts near the hospital, from which it would appear that other hospitals of this type could cater for masses of the population even in London by whom the Maudsley is regarded as too distant for attendance.

Although generally speaking the admissions to the Maudsley Hospital are restricted to cases with a good hope of recovery, such cases may vary enormously in severity; and it has sometimes been said that the presence of severe cases would deter those suffering from minor psychological disorders (for example, neuroses) from seeking admission. In reply to this criticism, Dr. Mapother instances two sorts of comment frequently expressed—one that the patients in the quieter wards are not "mental" at all, the other that the more acute cases do not differ from those in ordinary mental hospitals. Although neither of these comments is true, yet taken together they refute the assertion that the reception of severe cases causes the mild cases to refrain from applying. Dr. Mapother considers that the treatment of mild and severe cases in one hospital is not only practicable, but advisable.

The out-patient department continues to be the main channel of admission for in-patients; about three-fourths of those treated in the wards have first been examined in the out-patient department. This department also serves a very useful purpose in the giving of advice in cases where no indoor treatment is undertaken. One of the features of the second year has been the extent to which continued out-patient treatment has developed. In the great majority of cases where the disorder is recent and is of hopeful form admission is arranged so that the patient may have the greater advantage of treatment in the wards. Continued out-patient treatment is therefore for the more chronic type of case, and, although mostly only palliative, it has proved to be of great value in very many instances.

Dr. Mapother draws attention to the danger of encouraging chronic neurotics to use hospitals as a refuge instead of facing difficulties outside. Consequently in very many of such cases out-patient treatment is to be preferred. "The problem of discriminating cases that require, on the one hand, physical and mental rest, or, on the other, active mental investigation and stimulation, is one of the most fundamental and difficult in regard to all types of mental disorder." With regard to the therapeutic measures adopted, it is noted that subcutaneous injections of hyoscine hydrobromide have appeared to arrest downward progress in cases resulting from encephalitis lethargica. Such cases are much more numerous than formerly. In many of them the initial attack had been overlooked: the majority were brought to hospital on account of the mental symptoms. In a number of such cases distinction from ordinary melancholia presented very real difficulty. Cases of neuro-syphilis have been treated by tryparsamide. Many cases showed distinct improvement either clinically or serologically. Serological improvement did not necessarily accompany clinical improvement. Anxiety cases with signs of hyperthyroidism showed real improvement as a result of administration of parathyroid, especially when combined with calcium.

Dr. Frederick Golla, director of the Central Pathological Laboratory, has been engaged in the standardization of various methods for the study of internal secretions. Investigation into the abnormalities of internal secretion promises to be of great value.

Sir Frederick Mott has continued to act as director of the course for the Diploma in Psychological Medicine.

The whole report makes most interesting reading. The work undertaken at the Maudsley Hospital is of the highest value; and that the unique opportunities it affords for treatment and research have been so skilfully utilized reflects great credit on Dr. Mapother, the medical superintendent, and on Dr. Golla, who directs the research work.

Scotland.

DR. JESSIE MACGREGOR PRIZE.

THE Dr. Jessie Macgregor Prize in Medical Science, of the value of 60 guineas, is open to medical women who are graduates in medicine of the University of Edinburgh, or who have taken the triple qualification, and who, before becoming qualified, have studied medicine for at least one year in Edinburgh. An award will be made in July next to the applicant who presents the best record of original work in the science of medicine. Such work may be published or unpublished, but must not have been published earlier than three years prior to July, 1926. It is a condition of the award that the successful applicant shall, within six months following the award, deliver a lecture to the medical profession in Edinburgh on the subject of the work for which the prize has been awarded, such lecture to be entitled "The Dr. Jessie Macgregor Lecture." Applications, marked "Dr. Jessie Macgregor Prize in Medical Science," must reach the Convenor of Trustees, Royal College of Physicians of Edinburgh, not later than June 30th, 1926.

THE ROYAL INFIRMARY OF EDINBURGH.

At a meeting of the board of managers of Edinburgh Royal Infirmary held on March 22nd it was announced that Dr. W. Hope Fowler and Dr. A. McKendrick had resigned

from the posts of senior medical electrician and junior medical electrician respectively. The board minuted its appreciation of the services of these two medical officers. The former had been associated with the medical electrical department for nearly twenty-five years and had succeeded Dr. Dawson Turner as senior medical electrician in 1911. Dr. McKendrick had held the post of junior medical electrician since 1911. It was also reported that the receipts of the Royal Infirmary during the past three weeks had amounted to £28,084. This included a donation (announced in our issue of March 20th) of £10,000 from Sir John R. Findlay, Bt., for the purpose of extending the site of the institution. It also included several important contributions from approved societies in recognition of treatment received by their members. It was also reported that the number of cases awaiting admission to the institution on March 1st was 2,227.

CHURCH OF SCOTLAND DEACONESS HOSPITAL.

At the annual meeting of the Church of Scotland Deaconess Hospital at Edinburgh, Professor G. M. Robertson, President of the Royal College of Physicians, Edinburgh, who moved adoption of the annual report, said that the beneficent work this hospital was doing was of the most varied character, and among its numerous activities one of the most appreciated was the out-patient department, at which in the preceding year there had been over 16,000 attendances. This number was increasing steadily and was of invaluable service to the crowded population of the neighbourhood. The speaker thought that the voluntary hospitals of this country formed the most perfect embodiment known to them of the combination of humanitarianism and medical science, and gave a tangible expression to the highest ideals of Christianity. While this could be applied to the voluntary hospitals in general, he wished to apply it in particular to the Deaconess Hospital of the Church of Scotland, which served one of the poorest districts of Edinburgh. A feature of this hospital was the large proportion of its nursing staff which aspired to follow a religious calling, and after they had received their training many became missionaries. They exercised over their patients an influence of a wise and reasonable kind, although they employed no ecclesiastical technique and made no special claims for the curative powers of the services they rendered. It seemed to him that this was one of the best and sanest forms of spiritual healing, which aimed definitely at strengthening the whole life, especially the spiritual life. On the other hand, he deprecated such practices as unction and the laying on of hands, which were misunderstood by the ignorant, but the Church of Scotland and the Deaconess Hospital were to be congratulated on having provided an opportunity of an unimpeachable character for those who cared at the same time for the soul and for the body and wished to exert a ministry of healing. In conclusion, Professor Robertson said the board had now a serious responsibility in providing an income of £6,000 a year for the services of the hospital, and it relied on the continuance of the generous support of the many friends of the hospital throughout the Church of Scotland. The chairman, Lord Sands, in referring to the annual report, said that the total number of patients who had received treatment in the various departments of the hospital's work during 1925 amounted to 6,274. The income during the past year had been £5,930 and the expenditure £5,623. They were, however, not content with the situation, and as the hospital had commenced from very small beginnings they should look forward to extending its work. A vote of thanks to the medical and surgical staff and the nursing staff was proposed by Miss Lamond and acknowledged by Dr. H. L. Watson Wemyss, assistant physician to the hospital. It has been suggested as a suitable expansion of this hospital's work that the institution should be divided into two parts. The present building might be retained as an out-patient clinic, serving the great needs of the district in which it is situated, with a certain number of beds for emergency cases and maternity work, while the hospital, as it deals with patients admitted from parishes of the Church of Scotland in outlying parts of the country, might be removed to a more salubrious locality in the suburbs of the city. This would require the donation of a large capital sum.

Ireland.

ROYAL VICTORIA HOSPITAL, BELFAST.

THE annual meeting of the Royal Victoria Hospital was held on March 26th in the King Edward VII Memorial Hall. The Lord Mayor (Sir William Turner) presided, and, in moving the adoption of the reports, congratulated the board of management on the completion of the new building, which provided three new wards, with eighty additional beds, three new operating theatres, two new clinical theatres in the extern department, a much enlarged dental section, a new and enlarged accommodation for the eye, ear, and throat departments, and a new nurses' home, to be called the Musgrave Memorial. The memory of the late honorary secretary, who had worked for the hospital for seventeen years, was to be perpetuated by a window, presented by his family. The financial statement showed receipts amounting to £55,625, and disbursements to £56,327, a favourable position equalled by few hospitals in the British Isles. Mr. J. H. Stirling, in seconding the motion, drew attention to the necessity of providing for the middle-classes hospital accommodation equipped with all the modern accessories of hospital work. Mr. Mitchell, chairman of the medical staff, proposed the adoption of the medical report, and referred to several matters of public medical interest. The motion was seconded by Mr. J. A. Craig, who referred to the much needed enlargement of the dental section, and the general excellence of the equipment.

ULSTER MEDICAL SOCIETY.

The President and Mrs. Craig received the Fellows and Members of the Ulster Medical Society and their friends on the evening of March 25th in the Medical Institute, Belfast. The rooms were gracefully decorated, and some excellent music was provided. Old friendships were renewed and the more lately joined members had an opportunity of enjoying the social relaxation which does so much to lighten life in the profession and to promote friendship and goodwill. All felt that they were under a deep debt of gratitude to Mr. and Mrs. Craig for their great trouble and kindness, and their very welcome hospitality.

England and Wales.

ST. ANDREW'S HOSPITAL, DOLLIS HILL.

THE St. Andrew's Hospital, Dollis Hill, London, was opened in 1913 for the reception of patients of the professional and middle classes, who, while unsuitable for free treatment in charitable institutions, are unable to meet the charges in private nursing homes. During 1913 the number of patients admitted was 540; in 1924 this had risen to 742, and in 1925 to 900. The thirteenth annual report of the hospital shows that the average number of patients resident daily was forty in 1924, and fifty-two in 1925; the number of operations performed in 1925—the year under review—had also increased by 27 per cent. Although there is no regular out-patient department at the hospital it has been necessary to treat 365 cases of accident and emergency. An additional lift has been installed to facilitate the transport of patients. The hospital has now been recognized as a certificated training school for nurses by affiliation with the Royal Free Hospital. It has not yet been possible to provide a nurses' home, which would enable the beds for patients to be increased from fifty-two to sixty-four or more; it is estimated that a sum of about £14,000 would be required, of which over £1,000 has been collected. The hospital was visited by Queen Alexandra in 1918, and was subsequently placed on her private list of grants in connexion with Alexandra Day. Further improvements contemplated include the extension of the present x-ray department and the establishment of an electrical department. The hospital is under the care of the Sisters of Mercy, and the trustees include Cardinal Bourne, Archbishop of Westminster.

LIVERPOOL ROYAL INFIRMARY.

The report presented by the chairman to the annual meeting of the Liverpool Royal Infirmary on March 30th set forth a considerable increase in the work of the various departments. The number of in-patients admitted in 1925 was 5,556, showing an increase of 487 over 1924. The out-patients numbered 32,475 in 1925, being 1,285 more than in 1924. The financial statement, like those of the four big voluntary hospitals in the city, revealed a deficit; it had accumulated to £29,142. The excess of total expenditure over income in 1925 amounted to £4,932. The only hope of these voluntary institutions paying their way seemed to be the launching of a systematic contributory scheme such as is at present engaging the attention of the Lord Mayor's Committee. Before the new nurses' home could be completed some £10,000 was required, and an earnest appeal for this object was made. Since 1919 every penny of free legacies had been expended on maintenance, and although the income for 1925 had gone up by £680 the expenditure steadily increased. All those who addressed the meeting emphasized the importance of a contributory scheme similar to that which is already in operation in other large towns. Mr. T. C. Litler Jones, who recently retired from the surgical staff after twenty-three years' service, was elected an honorary consulting surgeon. Sir James Barr, consulting physician to the Royal Infirmary, had the honour of being unanimously elected to the post of president for the ensuing year.

Correspondence.

THE "SPECIAL REPORT SERIES" OF THE MEDICAL RESEARCH COUNCIL.

SIR,—As noted in your issue of February 6th (p. 253), the Medical Research Council recently passed for publication a statistical study of the incidence of fatal cancer upon males in various occupations. This report was the work, and specifically stated to be the work, of Dr. Matthew Young and Mr. W. T. Russell, who had collaborated with Dr. Brownlee and Professor Collis. In your issue of March 6th Professor Blair Bell has criticized a passage in Dr. Young and Mr. Russell's report, termed by him a report of the Medical Research Council. Of the merits of the controversy I need say little. Dr. Young and Mr. Russell, like other experienced statisticians, are fully aware of the fact that, if a statistical group sufficiently large to afford arithmetically significant index figures be taken, it is probable that exposure to a specific risk is not equally distributed through it. What they tested was whether there were an inverse correlation between a group-measure of lead poisoning and a group-measure of cancer incidence. They found there was no such inverse correlation and, in my opinion rightly, stated that the connexion was not proven. The criticism passed upon this analysis might also be passed upon a comparison of, for instance, mortality rates from enteric fever in different cities. The "risk" is not equally distributed over the inhabitants and the comparison is only a rough one.

All statisticians would like better data than are provided, but they can only use the data that exist and express their conclusions, as Dr. Young and Mr. Russell did, with reserve. Anything less committal than the conclusion "that these data do not reveal the connexion suggested between cancer and lead poisoning" would be hard to imagine.

My reason for writing is, however, more important than this rather trivial point. Not only in your issue of March 6th, but still more pointedly in an address reported in your issue of March 27th, Professor Blair Bell has implied that Dr. Young and Mr. Russell's report is an official utterance of the Medical Research Council. "One would have expected," he writes, "better things from the Medical Research Council, with its strong statistical committee, than that it should take a group like potters, 80 per cent. of whom never went near lead at all." Professor Blair Bell has made these statements in spite of the facts (1) that the names of the authors appear on the report; (2) the

Council's preface explicitly stated that its Statistical Committee considered certain aspects of the report to be controversial.

If, in the face of the evidence, misstatements such as those of Professor Blair Bell become current, much of the value of the "Special Report Series" will be destroyed. An important, almost the most important, object of that series has been to give publicity to work of competent investigators which, often on account of cost of production, might not otherwise appear. The responsibility of the Council and its technical advisory committees is limited to a guarantee that the method of research employed is adequate, the guarantee being, when the condition is not wholly fulfilled, limited and defined in the preface. Cases must arise where there is doubt; and in these cases the benefit of a doubt is always given to the individual. If this system, which has been many times explained, is to be ignored, and everything printed under the sanction of the Council perversely described as an official pronouncement by the Council, the character of the reports will be wholly changed.

In my opinion, it is a grave offence that the Council's efforts to maintain freedom of research and publication in medical science should be endangered by misstatements. Of the discourtesy to the gentlemen who have carried out a laborious inquiry I need not speak.—I am, etc.,

MAJOR GREENWOOD,
Chairman of the Statistical Committee
appointed by the Medical
Research Council.

Loughton, March 30th.

VITAMIN DEFICIENCY.

SIR,—In a leading article on the above subject which appeared in the BRITISH MEDICAL JOURNAL of February 6th (p. 250) the following passage occurs:

"... the importance of vitamin supply in clinical medicine has been underrated. The idea has spread that so long as such diseases [polyneuritis, keratomalacia, scurvy, and fulminating rickets] do not occur people are receiving an adequate vitamin supply, and all is well. Professor Plimmer's experiments¹ shatter this comfortable belief."

The last part of this passage has surprised me; for I imagined that my own experimental and pathological researches had initiated the shattering process some years ago. Your leading article conveys the impression that the conception of partial vitamin deficiency as the cause of "a series of effects which are among the commonest complaints of civilized man" is a novel one; and that the scientific facts on which this conception is based are equally new. In point of fact both the conception itself and the facts in support of it date from the publication of my papers on the pathogenesis of deficiency disease (1919-20) and of my book *Studies in Deficiency Disease* (1921). The theme of this book was clear—namely, to show that it was not with complete vitamin deficiency that the physician had to deal, but with partial vitamin deficiency. Nor was its theme in doubt by reviewers. Thus one, a British pathologist, wrote:

"He [Colonel McCarrison] is less concerned with the demonstration of an end-result, such as scurvy, polyneuritis, etc., brought about by exhibition of a diet wholly deprived of the particular vitamin concerned, than with the sundry pathological effects on the various systems of the body produced by partially avitaminic or ill-balanced or deficient diets generally."

I was at pains to make it perfectly clear that it was because of my use of such "partially avitaminic" diets that the pathological results which I observed in my animals—pigeons, guinea-pigs, and monkeys—might be expected to approximate closely to those "in human beings suffering from partial avitaminosis" (p. 27). I am surprised, therefore, to find in the brief account of Professor Plimmer's paper (BRITISH MEDICAL JOURNAL, February 6th, p. 239), where reference is made to the intestinal stasis which he observed in his birds, that he is reported to have said: "McCarrison had noted this intestinal effect as a preliminary stage in the production of polyneuritis in Pigeons deprived completely of vitamin B" (the italics are mine); the inference apparently being that I had not noted

this intestinal effect in animals partially deprived of vitamin B. It was, on the contrary, precisely because my experimental diets were not devoid of this factor that my animals survived for comparatively long periods, thus enabling me to make the pathological observations I did, and to evolve the very conception—which your leading article now says "Professor Plimmer's experiments suggest"—that "a large proportion of the chronic disorders of the alimentary tract from which our urban population suffers can be attributed to the deficiency of vitamin B in our diet": a conception, I may add, which has not only been the subject of many of my writings and lectures within recent years, but has also been emphasized by Dr. Cramer, who in a recent paper (1925) observes that "it is difficult to overestimate the etiological importance of vitamin underfeeding on the intestinal tract."

Prior to the publication of my studies on the pathogenesis of deficiency disease (some of which appeared in this JOURNAL in 1919) no systematic *post-mortem* examination of animals fed on food deficient in vitamin B had ever been made; the histopathological effects of such food on the various systems of the body were wholly unknown; above all, its effects on the gastro-intestinal tract and the organs of digestion and assimilation, and the significance of these effects for clinical medicine, were wholly unsuspected. Vitamins were at that time still spoken of as "antineuritic," "anti-beri-beric," and "antiscorbutic"—terms accurate enough in their limited way, but adjectival encumbrances which served to obscure the true relation of vitamins to normal metabolism and to normal cellular function. It was these methods of attack which, as admitted by the reviewer above quoted, "opened up new ground"; and, as stated by McCollum in his book *The Newer Knowledge of Nutrition* (1923), "introduced a new conception of the pathology of deficiency diseases," and "represented an important advance in our understanding of the relation of faulty nutrition of a certain type and physical degeneration." The pathological facts I thus obtained enabled me to predict that faulty food deficient in vitamins was a common cause of such human ailments as diarrhoea, constipation, chronic gastro-intestinal dyspepsia, gastric and duodenal ulcer, mucous disease, colitis, and chronic gastro-intestinal stasis—maladies which are "among the commonest complaints of civilized man," since they account for about one-quarter of his total illnesses (Sixth Mellon Lecture, Pittsburgh, 1921). Others have followed me in this field, in particular Dr. Cramer, who has confirmed and amplified my observations on the gastro-intestinal tract, defined more specifically the effects of "vitamin (A and B) underfeeding" on this tract, and added much to our knowledge; and now Professor Plimmer, the results of whose experiments were the subject of your leading article.

The question of vitamin deficiency, in so far as it relates to vitamin B, and in so far as it concerns clinical medicine, is, and in truth has always been, one of partial and not one of complete vitamin deficiency. Clinical medicine has little or no concern with the latter, and for this reason: that outside the laboratory there is no such thing as a vitamin-free diet. Even beri-beri itself is never associated in India with the use of a diet which contains no vitamin B; although it is very commonly, if not constantly, associated with a diet which contains too little of it. Nor is there a rice in common use in India which is wholly lacking in vitamin B. Similarly, there is no such thing in nature as a diet wholly devoid of one vitamin while complete in every other way. Always when there is deficiency of one vitamin there are other food faults besides: deficiency of another vitamin, or of inorganic salts, or of suitable protein, or excess of carbohydrate, or ill balance of the diet in other respects. Consequently, those of man's ailments—especially his gastro-intestinal ailments—which are due to his faulty food are the result of the peculiar combinations of its faults, together, in many cases, with the superimposed effects of pathogenic agents. It is the faulty food deficient in vitamins which results in "depreciation of cellular function, and depreciation of cellular function is the foundation upon which disease is built" (*Studies in Deficiency Disease*, p. 211).—I am, etc.,

LEAD IN THE TREATMENT OF MALIGNANT DISEASE.

SIR,—Since the meeting at the Medical Society of London on March 22nd hopes have been expressed by my friends that I would refute this or that statement after having had an opportunity of looking up the papers concerned, for, at the time, not having them with me, I had to be content with a general disavowal or an apology. I am, however, extremely loath to say anything more. Dr. Adami has already shown (*BRITISH MEDICAL JOURNAL*, March 27th, 1926, p. 594) how perverted certain criticism was, and how easily refuted. What he has said applies to nearly every adverse statement made in regard to our methods, and to the alleged "sloppiness" of our publications. Nor shall I be so ungracious as to ask for the correction of the one or two small verbal mistakes made in the excellent accounts of the meeting given by the medical reporters present. It was better that the accounts of such a meeting should be compiled by independent recorders rather than based on the usual abstracts sent in by the speakers.

There is, however, one matter to which, with Mr. Fitzwilliams's concurrence, I should like to refer. It will be remembered that Mr. Duncan Fitzwilliams made great play with a vivid description of a letter he said he had received from me—a letter which he thought illustrated bad faith on my part. In my reply I ventured, from memory, to deny ever having dictated such a letter, and I suggested what I had probably written. Mr. Fitzwilliams, it will be recalled, then rose in his place and contradicted me. Thirty-six hours later I received the following letter from him:

"I am so sorry and I apologise most humbly for having contradicted you in what you recollected of having written to me.

"Last night I asked my secretary to look up your letter, but left the house in a hurry and did not take it with me—it was lying on my desk when I came home and it is exactly as you said, you have put my name down for notification for some time perhaps in April. I visualized your letter as something quite different, and having got it in my head I have not the vaguest idea with what I have mixed it up—I am indeed sorry.

"Let me add my congratulations on the success of your meeting last night. I know perfectly well from what I had heard that you had met a not too friendly audience, and that you carried them completely with you must be a very great satisfaction to you.

"I shall look forward with great pleasure to seeing you in April."

This is the letter of a gentleman. Nevertheless, such mistakes should be avoided. Confident assertions and re-assertions may produce an impression on an audience which is not always removed by a declaration of the truth at a later date.

I feel sure that when Mr. Fitzwilliams comes to see us in a few weeks' time, so honourable a critic will realize and confess that we have neither magnified the dangers and difficulties, nor overestimated the results we have obtained. Be this as it may, he will receive a cordial welcome, as have all those who during the last few years have visited us.—I am, etc.,

Liverpool, March 28th.

W. BLAIR BELL.

SIR,—Many reading the *JOURNAL* of March 27th (p. 570) must find themselves deploring the character of some of the criticisms levelled against the sincere and scientific effort of Professor Blair Bell and his Liverpool colleagues to help us in our urgent daily problem of the treatment of the most terrible of all diseases. Their striking results with lead justify their plea that for serious cancer workers the question must now be raised from the level of ordinary laboratory polemics into a fact of great importance to science and to the community at large. Many must be glad that Professor Blair Bell and Dr. Adami have dealt so effectively with the criticism of Dr. Leitch. The animadversions of this observer are typical of an attitude of mind which within recent times has seriously lowered the value of many of the pronouncements on cancer questions which emanate from London, and which appear not only in the medical but also in the lay press. In this connexion I may cite my own experience at a recent meeting in London where I urged in support of my investigations into the nature of the cancer parasite the fact that eight workers in five different laboratories (in Berlin,

California, New York, Montana, and Toronto) had confirmed my discoveries. At that meeting Dr. Leitch's only reference to this multiple confirmation was an attack on the personal character of one of these foreign investigators. Moreover, he revealed his inadequacy as a scientific observer in his admissions regarding a test experiment which I had carried out at his laboratory on behalf of the Medical Research Council. At this experiment I undertook to produce the pseudo-leukaemic or lymphosarcomatous lesion, which I had previously obtained with the experimental inoculation of my micro-organism; a lesion the significance of which other well known cancer workers have acknowledged, and which has been reproduced under similar conditions in at least one other laboratory. Dr. Leitch had to admit that he had thrown away the dead mice without a microscopic examination of the organs in which the lesion is known to occur. Subsequently in my presence the eleven surviving animals of this experiment were killed and examined, and in two advanced lesions were found. When taxed with these facts Dr. Leitch made the remarkable statement that this leukaemic lesion was of no significance as it was "found in every laboratory mouse"! The error behind such a statement is revealed by the fact that Simonds in Maud Slye's laboratory in America found that the lesion, which I have described, and which these workers also regard as a malignant tumour, occurred spontaneously in only 229 out of 15,000 mice autopsies—that is, in 1.5 per cent. I made this refutation at the meeting referred to, but in view of the importance of the subject, and as Dr. Leitch has published a report of this test experiment likely to prejudice my research in the eyes of those unacquainted with all the facts, I ask the courtesy of your columns to make it more widely public.

Whilst we cannot always expect criticism to be broad-minded we can at least demand that it be informed and fair.—I am, etc.,

Edinburgh, March 27th.

JAMES YOUNG.

SIR,—Will you allow me to correct an error which appears in the report of the discussion on the treatment of cancer by lead preparations on page 571 of your issue of March 27th?

I am made to state that 100,000 deaths occurred from cancer in England and Wales in 1925; it should have been in 1924 and 1925, the figure for 1925 being based upon the fact that over 50,000 deaths occurred in 1924. No definite figures for 1925 are available.—I am, etc.,

London, W.I., March 28th.

CECIL A. JOLL.

LONDON UNIVERSITY SITE.

SIR,—In your issue of April 3rd your editorial upon this subject closes with the statement: "The Senate, therefore, appears to have come round completely to the opinion that the University ought to move to the Bloomsbury site. . . ." If by the term "the University" its ordinary acceptance is meant—namely, the central administration at present housed at South Kensington—the statement is incorrect. Moreover, the condition that King's College should remove to Bloomsbury, and hand over its existing site and buildings to the Government, was not a mere senatorial interpretation of Mr. Fisher's offer, as your editorial suggests; the condition was explicit in Mr. Fisher's letter of April 7th, 1920, elaborated in Mr. Fisher's letter of June, 1920, when he promised to seek parliamentary sanction for compensating King's College for its buildings "at a fair valuation" (a promise not fulfilled by Mr. Fisher), and categorically reaffirmed by the Chancellor of the Exchequer in March, 1924, when he plainly told the University that unless King's College and the University administration could agree by April 1st, 1926, to remove to the Bedford site that site would be handed back to the Duke. There was no possible ambiguity about this statement, and the decision now reached cannot be described as a "bombshell" to those acquainted with the facts.

There can be little doubt that the Treasury offer, conveyed in Mr. Fisher's letter of April, 1920, was chiefly actuated by the Treasury's desire to obtain possession of

the King's College premises; by that offer the Treasury would have secured the Strand site and buildings for an equivalent which was approximately only one-tenth of their value. Naturally, King's College was reluctant to accept this remarkable financial "bargain."

The Senate notified the Treasury in July last that it found itself obliged to decline the offer of accommodation of the central administration at Bloomsbury on the terms of Mr. Fisher's letter of April, 1920. The letter of October 27th, cited by you, embodied a resolution of the Senate which was itself a compromise, and was very carefully worded. The quotation in your editorial contains only a portion of the request then made, and is so far misleading. The request was for increase of accommodation for the central administration in the Imperial Institute (this is omitted from your quotation), and for utilization of such parts of the Bloomsbury site as might be still procurable, the Treasury letter having mentioned that "at least a part" of the site might be occupied for other university purposes "upon terms" to be arranged with the vendors. The Treasury further notified the Senate that if alternative plans for the increase of this accommodation of the central administration could be suggested, without involving undue cost, the Treasury would be prepared to consider them. In accordance with this invitation architects have been invited to prepare plans for increasing the space utilizable by the University at South Kensington, and plans have been actually submitted which show the possibility of an augmentation of 50 per cent. at least upon the present accommodation. These proposals must form part, and probably the only practical part, of the negotiations which the recently appointed deputation is to undertake with the Treasury. In reply to a question put by me last week in Parliament, the Chancellor of the Exchequer stated that "Notice has been served upon the solicitors of the Bedford Estate offering the resale of the Bloomsbury site to the Duke of Bedford in accordance with the terms of Clause 7 of the Conveyance of 1921." Inasmuch as it is certain that the site could be sold now for a much larger sum than was paid for it in 1921, it is improbable that the trustees of the Bedford Estate will forgo their present option of repurchase at the 1921 price; whether that be so or not, it is clear that the Treasury has no longer any say in the matter, and the discussion between the University and the Treasury must be limited to the sole alternative at present practicable—namely, the expansion of the existing accommodation for the central administration at South Kensington.—I am, etc.,

Worthing, April 5th.

E. GRAHAM LITTLE.

MENTAL IRRITABILITY AND BREAKDOWN IN THE TROPICS.

SIR,—As one who has practised in the West Indies, and in West and Central Africa, I suggest that for the elucidation of the above problem (as in others of tropical medicine) the West Indies and British Guiana provide the necessary and informing control.

For three hundred years numerous white families, still of unmixed European blood, have been born, bred, worked, and died in the West Indies. Fair and dark, brown, red, and freckles are found in almost equal proportion among them. These families have survived through generations of tropical life to provide not a meagre quota of scholars and men of more than average ability. A considerable number of them live in a poverty of material environment and resource far below that enjoyed by all but a very few Europeans in tropical Africa or the East. Only superficial observers find in these white West Indians any sign of racial deterioration. The regret of these families to-day is the difficulty of finding for all their sons satisfactory careers at home, in the West Indies. Their numbers are added to by newcomers from Britain. Mental breakdown, or "nervous" trouble, is so little a feature of medical practice among these whites, West Indian and newcomers alike, as so far to have escaped any record. White native-born West Indians often serve in tropical Africa or the East; they may be invalidated from those countries for "neurasthenia"; and make complete recovery on returning, to work, in the West Indies. Three such cases have come under my medical care since the end of the war.

In the West Indies and British Guiana may be found almost every variety of sun and tropical atmospheric conditions—glare, dust, wind or no wind, eye disease, parasitic disease, and insect pests. The whites live in the midst of a coloured population, with whom they go to school, and with whom they join in games, and in all religious, professional, economic, and legislative affairs.

The "irritability" of the whites is perhaps now confined to the elders, and is not more than that recorded in literature as a mark of a privileged aristocratic class in its dealings with its social inferiors. (It is, in fact, not unknown among the upper classes of the coloured folk.)

The whites in the West Indies do not suffer from mental breakdown, because they are *at home*. Their coloured compatriots do not speak a different language, practise a different religion, wear different clothes, nor entertain different social, economic, or ethical ideals. The standard aimed at by the whole community, coloured and white, is European and British. There is keen local patriotism ("provincialism" it may be) shared equally by all colours. The white newcomer does not find himself in a foreign community. The white man in the West Indies, whether newcomer or native, is socially integrated with the whole parti-coloured community in which he lives. It is not so in the East. In tropical Africa it may become so, for it is to be noted that the white man, after serving his time, has begun to go back to live, and die, "at home," in West Africa. Mental irritability and breakdown of the white man in the tropics is not directly a medical problem, but rather the psychological one of citizenship and the herd. It is a matter on which the Bishop of Singapore might, with profit, compare notes with his brother of Barbados, or Jamaica, as well as consult the medical profession.—I am, etc.,

London, W.I, March 30th.

H. M. HANSCHALL.

SIR,—The causes of breakdown in the tropics have been very fully given by your correspondents. I only add a few points of treatment I have found useful during a long residence in North Indian plains, East and South Africa.

1. Avoid entire isolation from congenial associates. If a man must live alone, let him visit his equals monthly or at least quarterly.

2. Avoid food deficiency—African chickens and Indian flour (as bought) have not the nutritional properties of their English namesakes. If one eats debris and adulterations one must eat more to get the same nutrition. The ship's captain who dined off an apple probably had really good food at his other meals. My experience is when English go native they adopt rice as their mainstay, and the result is disastrous.

3. A proper holiday is indicated at least once a year, either in health resort or capital, according to temperament. I am not struck by the results of the frequent home leave given in the African colonies. Doubtless they are at present the best that can be done in these unsatisfactory countries, but the health of their English community compares badly with that of the English in India, and I fancy the English missionaries in Madagascar, who go out for long periods have much less invaliding than those in Tanganyika, where the maximum stay is three years.—I am, etc.,

London, E.17, March 27th.

M. ILES.

SIR,—During the winter of 1918-19 I was in North Russia, my headquarters being at Archangel. As consulting physician to the Allied Forces I had the opportunity of observing the effect on our troops of climatic conditions diametrically opposed to those described by your correspondents.

During the greater part of the winter this part of North Russia is a vast, silent, featureless, snow-clad pine forest. In midwinter there are only a few hours of daylight in the twenty-four, and little direct sunlight. Locomotion is very largely by sleigh and consequently almost noiseless. Train services are infrequent and very slow. The Russians are extremely unpunctual and are never in a hurry. Taken singly, these points may seem to be trivial, but collectively the summation of stimuli have a curiously depressing effect on the mind of the average Englishman, accustomed as he is

to the ceaseless bustling activity of modern English life, with warmth, noise, and constantly varying conditions of climate, scenery, and surroundings. Isolation from home, impossibility of leave, lack of opportunity for recreation, infrequent and imperfect mails, added to this depression in 1918-19.

The usual cases of early organic nervous diseases occurred, but the outstanding feature of the nervous class of diseases was the frequent occurrence of various forms of neurasthenia.

The depressing conditions of life in North Russia were particularly unsuitable for neurasthenics, and the danger of suicide had to be constantly borne in mind. Waves of suicide are frequent in Russia, and I was forced to regard all cases showing indications of grave depressions, obsessions, marked and abnormal irritability, or change of disposition, as potential suicides, and to recommend evacuation of such cases to England as soon as possible. Insomnia was common and was an additional factor in the causation of this condition.

These observations, which I have quoted almost verbatim from the report I made at the termination of my tenure of office as consulting physician, would tend to show that environment rather than climate is the main factor in the causation of such cases of neurasthenia, whether in tropical or arctic regions.—I am, etc.,

E. RIVAZ HUNT, M.D., M.R.C.P.

Brighton, March 29th.

COMMON SENSE IN RELATION TO DOUBTFUL TUBERCULOSIS.

SIR,—Most tuberculosis officers will confirm the really disastrous social consequences resulting from loose diagnoses of tuberculosis. As to the possible lethal effects, Dr. E. Weatherhead agrees "on general principles" that "suspects under observation at a sanatorium should preferably be accommodated in separate 'observation sections.'" I cannot agree with him that there is no appreciable risk of infection of non-tuberculous persons at a well ordered sanatorium, and the latter must be classed as "well ordered" if "approved" by the Ministry of Health.

I know of a series of cases of tuberculosis occurring in the staff of a Devon sanatorium in which there was good reason to suspect it was contracted in the institution. The latter was structurally imperfect as a sanatorium, but was "approved" by the Ministry and thus "well ordered." The risk in sanatoriums of infection from person to person is one of dosage or degree of exposure to infection, and this may be less than in the outside world, or, again, it may be more.

Thus, in a sanatorium without separate sections, a non-tuberculous person may sleep in a double cubicle or ward with an early open (positive) case, and spend ten to twelve hours out of twenty-four in close proximity for three to six months, and thus be potentially exposed to aerial spray from sputum—for example, if they play draughts, etc., together—or to dust from infected bedclothes, however "well ordered" the place may be. Would a good tuberculosis physician advise or allow a non-tuberculous relation or patient to cohabit with positive tuberculous ones knowingly? Would we willingly do it ourselves?

My conclusion is that, justly as we pride ourselves on our control of infection and over our patients' mode of life at sanatoriums, such can be relative only, and not absolute, and I believe that a tuberculosis sanatorium is very definitely one of the places to which we should never send debilitated non-tuberculous persons, unless it has an observation section.—I am, etc.,

Plymouth, March 23rd.

F. G. BUSHNELL, M.D.

SIR,—I welcome the contribution of Dr. Vere Pearson (March 27th, p. 596) to the correspondence on this subject.

The infectivity of tuberculosis has become grossly exaggerated in the public mind, and the medical profession and—notably—American antituberculosis propaganda methods are largely to blame for this. I frequently find myself, in response to the inquiries of patients or their friends, explaining that tuberculosis is not infectious

in the same sense as measles, scarlet fever, or small-pox. Granting Dr. Pearson's postulate—"If these things are realized"—I, too, would be with instead of against Dr. Mackey. But it is precisely because these things are not realized that I was led to write my protest. As soon as—to quote Dr. Pearson—"the half-knowledge leading to this wrong grouping" has been "turned into full acquaintance with the facts," I will join hands with him and Dr. Mackey. But I fear it will prove very difficult now to disabuse the public.

Only with one sentence of Dr. Pearson's letter am I unable to agree. He says, "Massive doses in unhygienic surroundings to susceptible individuals (who are generally either infants or adults from countries where the tubercle bacillus has not become implanted ubiquitously) are necessary conditions for the production of disease." The italics are mine. Surely we do not need to look to countries where the tubercle bacillus is not ubiquitous to find vast numbers of adults (and still more adolescents) who are susceptible to tuberculosis.—I am, etc.,

Alderley Edge, Cheshire, March 27th.

E. WEATHERHEAD.

Medico-Legal.

A SENTENCE UNDER THE DANGEROUS DRUGS ACT.

AT Marlborough Street Police Court, London, on March 29th, the stipendiary magistrate (Mr. Cancellor) sentenced Dr. Samuel Grahame Connor of Dryden Chambers, Oxford Street, to six months' imprisonment in the second division, and imposed fines amounting to £200, on charges made under the Dangerous Drugs Act, 1920, of failing on three occasions to enter in a register kept for the purpose a certain quantity—50 grains—of morphine purchased by him, and of failing in a prescription for morphine to specify the address of the person for whom the prescription was given.

Mr. Vincent Evans appeared for the Director of Public Prosecutions, at whose instance the summonses were issued, and Mr. Cyril Asquith appeared for the defendant.

Mr. Asquith entered a plea of guilty, and said that the defendant wished to be dealt with by that court.

Mr. Evans stated that a Miss Young, a drug addict, was early in 1921 convicted of forging a prescription in Glasgow, and Inspector Burnby discovered that she was being supplied with morphine by Dr. Connor. Dr. Connor, on being informed that she was being treated by another doctor, said he would discontinue treating her. In December, 1925, Miss Young was again interviewed in Glasgow by a representative of the Home Office, and, as a result, Inspector Burnby again saw Dr. Connor, and asked to inspect his register. Dr. Connor said he did not keep a register, or any stock of drugs, nor did he do any dispensing, and if patients wanted any morphine he prescribed for them. That was not true. Dr. Connor produced a day-book, which showed that between January 25th and December 27th, 1925, he had prescribed 575 grains of morphine on thirteen occasions, and had only seen Miss Young six times. Dr. Connor also said he paid his chemists' bills and never kept accounts, but his patients paid him what they liked. Recently he had a money order from Miss Young for £3, which represented about a guinea a visit. Inspector Burnby inspected the register kept by Bensons, chemists, which showed only one prescription made out in the name of Miss Young, but there were a number of "orders" signed by Dr. Connor and headed "for surgery use only," amounting to 850 grains. These orders, Mr. Evans submitted, were not prescriptions, but constituted "supplying" within the meaning of the Act. On December 14th, 1925, Dr. Connor himself obtained on one of these orders 50 grains of morphine and supplied it to Miss Young. Dr. Connor, when summoned, said he knew nothing about the regulations, and that he kept all he thought was necessary in his day-book, but that was not correct, as Inspector Burnby had warned Dr. Connor earlier.

The magistrate asked whether the persons alleged to have been supplied were drug addicts, and whether they had come to any disaster as a result. Mr. Evans replied "Yes," so far as one person was concerned.

Mr. Asquith said Dr. Connor pleaded guilty to the charges for which he was summoned but not to charges which he understood Mr. Vincent was now raising. It was true that Dr. Connor did not keep the full records in a register as the Act required, but he kept his day-book and there was never any attempt at any time to conceal or mislead. It had not been disputed that Dr. Connor had recorded every material transaction in his day-book, which was open as a register to public inspection. Precisely the same machinery was available for compelling scrutiny of a day-book as of a register. Dr. Connor, on being informed that his patient was receiving supplies from another source, merely assured the inspector that he would bring pressure to bear on the lady to have her supplies from one source only. Dr. Connor had merely committed a nominal breach of the regulations and a nominal fine would meet the case.

Inspector Burnby said Dr. Connor had been in practice in London for about twenty years, and witness first saw him in 1922 when there was a suspicion that he was treating patients who

were being treated by other doctors. Dr. Connor then gave him a list of drug addicts who were well known to be treated by Dr. Connor and other doctors. Dr. Connor was a specialist in drug cases and a large number of addicts known to the police were treated by him.

The magistrate, giving judgement, said it was absolutely necessary in the interests of the public that when a medical man broke regulations governing the supply of dangerous drugs he should be severely dealt with. Dr. Connor was a man who was not merely prescribing small quantities of drugs to people suffering from nervous diseases, but was making a practice of treating people who were addicted to drugs. So far as he could make out, the defendant had had ample warnings and had flagrantly disregarded them and had been carrying on a practice most deleterious to his patients. He therefore sentenced the defendant to two months' imprisonment in the second division on each of the first three summonses, fined him £50 on each of those summonses, and imposed a further fine of £50 on the fourth summons.

Notice of appeal was given on behalf of Dr. Connor.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

THE House of Commons stands adjourned till April 13th, when, on the Committee stage of the Economy Bill, debate will be resumed on the Government's proposals to alter the finance of the National Health Insurance scheme. The House of Lords reassembles on April 19th. The Coroners Bill has come down from the Lords, and is formally set down for second reading on April 13th, as is the Bethlehem Hospital Bill.

Economy Bill.

In a statement made during the Easter Recess to answer contentions advanced during the all-night sitting of March 31st on the Economy Bill, Sir Kingsley Wood declared that the Government would make every effort to secure the passage of the bill at an early date. So far from robbing the health services, the Ministry of Health Estimates for 1926-27 showed an increase of £600,000 in housing grants to £8,440,000, of £70,000 in the provision for maternity and child welfare to nearly £1,000,000, and of £125,000 in grants for tuberculosis to £1,500,000. All this expenditure was to the direct benefit of the community. The Government anticipated a saving of £1,000,000 by the abolition of the existing health insurance system. Not a penny of the surplus would be available for the first and second valuations would be touched by the Economy Bill. As a result of these valuations the Ministry of Health had already passed 3,500 schemes for additional benefits which had been submitted by approved societies or by branches. Practically all these schemes included dental benefit with a free choice of dentist to every approved person. Many of them also included optical treatment, the provision of medical and surgical appliances, convalescent homes, and hospital treatment. On the average the benefits provided by these schemes were more than double those obtainable under the schemes of 1921, which they replaced. The large reserves and increasing income of the approved societies and the high rate of interest now obtained justified the hope that at the third valuation in 1931 large sums would again be available above the normal benefits. The Royal Commission on National Health Insurance had recently recommended a service of medical specialists and consultants, and shown that this could be secured by a partial pooling of surpluses and other financial adjustments. This would prove a great advance, and one which the proposals of the Economy Bill would not hinder. He looked forward to an early day when, with the concurrence of the approved societies, the Ministry of Health would secure parliamentary sanction for these proposals. The Government did not further pledge itself on the recommendations of the Royal Commission. Sir Kingsley Wood emphatically denied that the Economy Bill would force the approved societies to reduce their grants to voluntary hospitals. In July approved societies would be able to increase their subscriptions to hospitals if they desired.

During the sitting of March 31st, which lasted till 9.30 a.m. on April 1st, the House of Commons only considered Clause 1 of the Economy Bill in committee. This clause proposed to reduce the State contributions to National Health Insurance to one-seventh in the case of men contributors and one-fifth in the case of women contributors. Mr. Harney moved the postponement of the clause, but after a long debate this motion was defeated. Mr. Lloyd George drew attention to the fact that the Advisory Committee representing the approved societies had declared against the proposal by 23 to 6. Mr. Lloyd George also contended that the clause broke a pledge given to the approved societies when the original National Health Insurance Bill was introduced in 1911. Mr. Chamberlain said he was unable to find any evidence of such a pledge. Since 1911 successive Governments had taken upon themselves the burden of the extra cost of diseases, estimated at £19,000,000 and £5,000,000 for minor charges.

On a subsequent amendment Dr. Drummond Shiels said that extended benefits were obviously in great danger under the bill. Officials of approved societies believed that the further extension of medical benefit would be prevented by this bill, and that in many cases they would be unable to pay the present extended benefit and to give extended medical treatment till 1931. The increased charge for medical benefit did not mean improved

payment for the doctors. He thought the bill would prevent the extension of dental benefit where it was already given, and in other cases would prevent its introduction. The same applied to optical benefit. A dental service was of tremendous value to public health, and optical benefit was also of great importance. The bill postponed the time when an increased maternity benefit of £4 or £5, which was the least that was useful or desirable, could be given generally, as it was now given by some societies. One of the worst features of the bill was that it postponed indefinitely the provision of specialist medical treatment. The Royal Commission put this as the first benefit to be given when funds were available. When a doctor attending an insured person desired a second opinion before advising a surgical operation the relatives now said it could not be afforded, and the doctor had to say, "We will have to try the hospital." In the six principal Scottish hospitals there was a list of 5,800 people waiting for beds, and he believed the same congestion prevailed in England. The committee which had been considering the Scottish hospitals question had reported that many of these people suffered as a result of their waiting, and that some even died. A new arrangement with the doctors must be made at the end of the year, and he was afraid that the inclusive specialist service which they would normally have had next year must now be put off. Many approved societies had themselves made arrangements with hospitals, nursing associations, dispensaries, and other organizations so that specialist service and institutional treatment might be secured for their members. This would now probably be cut off at once, because it was paid, not out of the surplus, but out of the ordinary benefit fund.

Sir John Simon said the Government might as well come to the House and announce to the medical profession that it had decided to alter to the doctors' disadvantage the arrangement made with them as to confront the approved societies with the proposals in the bill.

Mr. Chamberlain said dental benefit was now available as an additional benefit to something like 11,000,000 insured persons.

Clause 1 was eventually added to the bill by 169 to 104. The Committee stage of the bill is to be resumed on April 13th to 15th.

Coroners Bill.—The Coroners (Amendment) Bill was received in the House of Commons from the Lords on March 29th. It was read the first time and referred to the examiners of petitions for private bills.

Sexual Offences against the Young.—Sir W. Joynson-Hicks informed Viscountess Astor, on March 30th, that he would give special consideration to those recommendations in the report of the Departmental Committee on Sexual Offences against Young Persons which could be carried into effect by administrative action, pending the introduction of legislation regarding the remaining recommendations contained in the report.

Cost of Health Services.—On March 30th Sir Kingsley Wood stated that the total amounts provided by the Exchequer for national health insurance and for all other health services administered by the Ministry of Health or its predecessors (excluding grants out of the assigned revenues and the cost of central administration) in the financial year 1913-14 and in the estimates for 1926-27 were:

	Expenditure 1913-14.	Estimates 1926-27.
£	£	£
For other health services, included in 1926-27 grant in lieu of sanatorium benefit	183,434	3,076,190
Total	3,633,489	8,503,190

Mr. Chamberlain, in a written reply to Colonel Horlick on April 1st, said the total amount paid by the Ministry of Health or its predecessors from January 1st, 1919, to March 31st, 1926, by grants to local authorities or to voluntary associations for public health services, was £17,516,000. Sums amounting to £767,000 were also paid under the provisions of the Finance Act, 1911, and Section 64 of the National Insurance Act, 1911. The total amount paid as Exchequer contributions to National Health Insurance funds during the same period was £44,879,000. In addition, sums estimated to amount to £2,500,000 were paid during the same period to the councils of administrative counties and county boroughs in England and Wales, and applied towards the salaries of medical officers of health and inspectors of nuisances (or sanitary inspectors) and in fees to public vaccinators.

The Rum Ration.—The Secretary for War states that a free ration of rum may be issued under the authority of the general officer commanding when certified by the senior medical officer to be absolutely necessary for safeguarding the health of troops under canvas for musketry courses.

Social Hygiene in East Africa.—In a meeting of the Parliamentary Committee of the British Social Hygiene Council on March 30th, at the House of Commons, Mr. Greaves-Lord presiding, Major Keane, of the Uganda Venereal Diseases Service, spoke on the position in Uganda, the needs of the population there, and the improvement already effected in social hygiene during the past

fifteen years. Major Church, formerly a Labour member of Parliament and a member of the Commission of Inquiry in East Africa, gave an account of his impressions on social hygiene in East Africa and on the general medical and sanitary position in those territories. He declared that education was essential, and emphasized the importance of the medical service. Mr. Amery, the Colonial Secretary, was unable to attend the meeting, but his parliamentary private secretary said that the views expressed had the Minister's sympathy. It is understood that a discussion may be arranged in the House on the Colonial Office Vote after the Easter Recess.

Deaths from Small-pox.—In a reply to Mr. Groves, Mr. Chamberlain stated that in England and Wales from 1889 to 1906 inclusive 8,321 deaths from small-pox were registered, and in the years 1908 to 1925 inclusive 253 deaths.

Occupational Diseases.—Answering Mr. C. Edwards, Captain Hacking explained that miner's nystagmus, bent-knee, bent-elbow, and bent-hand were not included in the schedule of the Workmen's Compensation Act of 1925 because they were not specified in the corresponding schedule of the Act of 1906. The right to compensation in respect of these diseases remained unaffected. There was no need for special action in the matter.

Encephalitis Lethargica.—In replying, on April 1st, to Mr. Ammon, Mr. Chamberlain said the treatment of encephalitis lethargica which had been suggested by a Greek medical man and had been offered to the Ministry of Health had been considered by the experts of that department. Mr. Chamberlain said he was advised that the offer might most suitably be made to the managers of the institution at which arrangements had been made for the treatment of young persons suffering from the after-effects of this disease.

Universities and Colleges.

QUEEN'S UNIVERSITY, BELFAST.

The following degrees and diplomas were conferred on March 25th:

M.D.—J. A. Birkmyre, *A. E. Campbell, *B. R. Clark, H. M'E. Morris, J. F. O'Connor, W. W. Orr, D. K. Watterson.

M.Ch.—E. R. Frizelle.

M.B., B.Ch., B.A.O.—G. M. Frizelle, S. E. Bolton, F. C. Cassidy, R. Cocks, W. P. Colhoun, Margretta S. Earls, Rebecca E. Earls, Dorothy I. Enrican, Jane M. Ferguson, J. C. Gilbert, I. Hammel, Maureen P. P. Hamilton, S. Hanna, A. A. Hill, W. F. Lyle, T. B. Lyngagh, J. M. McClellan, T. McKee, T. Marques, J. K. Murphy, W. J. L. Neal, Grace K. Pollock, S. Rodgers, J. A. W. Sege.

D.Ph.—W. A. Kinlay.

* With commendation. † Gold medal. ‡ Second-class honours.

The Services.

AUXILIARY R.A.M.C. FUNDS.

The annual meeting of the members of the Auxiliary Royal Army Medical Corps Funds will be held at 2.30 p.m. on Friday, April 23rd, at 11, Chandos Street, Cavendish Square, W.1, when the annual report and financial statement for the year ended December 31st, 1925, will be presented, and the officers and committee for the current year elected.

NO. 55 GENERAL HOSPITAL DINNER.

The No. 55 General Hospital, B.E.F., reunion dinner will be held at the Trocadero Restaurant, Shaftesbury Avenue, on Saturday, May 15th, at 7 for 7.15 p.m. (dinner jackets). Old officers intending to be present are asked to communicate with Dr. H. B. Roderick, 17, Trumpington Street, Cambridge, as soon as convenient, in order that arrangements may be made.

DEATHS IN THE SERVICES.

Lieut.-Colonel Harold Samuel Peeke, R.A.M.C.(ret.), died at Beaumaris on March 21st, aged 61. He was born in London on December 17th, 1864, and was educated at St. George's, taking the M.R.C.S. and L.R.C.P.Lond. in 1887. Entering the R.A.M.C. as surgeon on July 27th, 1887, he became major after twelve years' service, went on half-pay on October 18th, 1908, and retired six days later. He served in the Nile campaign of 1898, receiving the British and Egyptian medals. After his retirement he was employed for some time at Derby, and on March 24th, 1915, was recalled to the active list for service in the recent great war. He was given the charge of the Liverpool Merchants' Mobile Hospital, with the rank of lieutenant-colonel, was mentioned in dispatches in the *London Gazette* of December 30th, 1918, and received a brevet lieutenant-colonelcy.

Lieut.-Colonel John Robert Yourdi, O.B.E., R.A.M.C.(ret.), of La Roque, Jersey, died in Jersey dispensary on March 23rd, aged 71. He was born at Hermopolis, in Syria, on February 6th, 1855, and was educated at Trinity College, Dublin, where he graduated as B.A., M.B., and Ch.B. in 1878. Entering the army as surgeon on July 30th, 1881, he became lieutenant-colonel after twenty years' service, and retired on February 6th, 1910. He served in the Egyptian war of 1882, receiving the medal and the Khedive's bronze star, and rejoined for service in the late war on November 19th, 1914, receiving the O.B.E. for his services.

Obituary.

SIR HARRY BROOKES ALLEN, M.D., LL.D.,

Professor of Pathology and Dean of the Faculty of Medicine, Melbourne University.

We regret to announce the death of Sir Harry Brookes Allen, in Melbourne, at the age of 71. He was born at Geelong, Victoria, in 1854, and received his medical education at Melbourne University, where he graduated M.B. in 1876, proceeding M.D. in 1878, and obtained the B.S. in 1879. After holding the posts of demonstrator of anatomy in Melbourne University and pathologist to Melbourne Hospital, he became lecturer in anatomy and pathology in 1881, and professor in 1882, which post he held until his death. He created the museum of pathology in Melbourne University. He was honorary secretary of the Medical Society of Victoria from 1879 to 1887, and editor of the *Australian Medical Journal* from 1879 to 1883.

Sir Harry Brookes Allen was a member of the Tuberculosis in Cattle Board from 1883 to 1884, and joint author of the report which was issued. In the same period he was a member of the Central Board of Health, and was responsible for the drafting of model by-laws for local boards. In 1883, as the result of his advice on meat preserving, the construction of the freezing chambers employed by the meat preserving companies of Australia was entirely altered, with very great benefit. He was the president of the Royal Commission on the sanitary state of Melbourne, and of the Intercolonial Rabbit Commission from 1888 to 1889, and general secretary of the Intercolonial Medical Congress in 1889. In 1890 he visited Europe, and obtained recognition for the Melbourne medical degrees. He drafted the deed of union of the medical societies of Victoria under the British Medical Association, was president of the Australasian Medical Congress in 1908, vice-president of the Section of Medicine of the British Medical Association in 1910, and a member of the executive committee of the International Medical Congress in 1913. He received the honour of knighthood in 1914. He was the author of *The Jubilee History of the Melbourne Medical School*, published in 1914, and of a series of lectures and demonstrations in pathology published in 1920. His numerous shorter publications include the reports of the Victoria Government on hospital construction, sewerage works, and other subjects, in 1891, and a report to the Commonwealth Government on health conditions in Panama, in 1913. Edinburgh University conferred the degree of LL.D. upon him in 1912, and he received the LL.D. of Adelaide in 1914. He married in 1891 the eldest daughter of the late Mr. Henry Mason of Liverpool, and had three daughters.

PROFESSOR THOMAS JONESCU,

Bucarest.

PROFESSOR THOMAS JONESCU, director of the first surgical clinic and the institute of experimental surgery at the University of Bucarest, died on March 27th, in his 75th year, after a long illness. He was well known to surgeons in this country and highly esteemed by them.

The relation of anatomy to surgery was always one of his chief interests, and in his earlier days, while residing in Paris, he devoted himself to the study of the gastrointestinal tract to such an extent that his name has come to be associated with the parieto-peritoneal fold and the duodeno-jejunal fossa. The wide range of his surgical interests is illustrated by the large number of his surgical publications, which include abdominal surgery, operations on the breast, and the surgery of the sympathetic system. He published a paper on general spinal analgesia in the *BRITISH MEDICAL JOURNAL* of November 13th, 1909 (p. 1396), in which he went far to establish the safety of intraspinal injections above the level of the lumbar region. He showed that puncture between the first and second dorsal vertebrae, or between the last dorsal and the first lumbar vertebrae, was easy, and could produce analgesia of all regions of the body. Although at that time considerable anxiety was felt as to the safety of the spinal method of producing anaesthesia, Jonescu was firmly

convinced that general spinal analgesia would become universally popular in the future. At a meeting of the Section of Surgery of the Royal Society of Medicine in 1909 he illustrated how this method was applicable to the surgical treatment of almost any part of the body. In November, 1909, he demonstrated his method at the Seamen's Hospital, Greenwich; three patients were treated, and it was shown that by the addition of a respiratory stimulant to the spinal analgesic the analgesia could be pushed far above the level of the respiratory centre without interfering with the respiratory tract.

In recent years his name has been particularly associated with the surgery of the sympathetic system in angina pectoris. The operation he recommended was cervico-thoracic sympathectomy, including removal of the entire cervical chain and of the first thoracic ganglion. This operation has, however, not gained universal approval, and Professor Daniélopou (JOURNAL, January 30th, 1926, p. 180) drew attention to its limitations. Professor Jonescu, in addition to his world-wide reputation for surgery, was for some time rector of the University of Bucharest.

The death is recorded of Dr. WILLIAM J. M. BARRY of Penarth on March 18th. He was born at Middleton, co. Cork, in 1865, and was educated at Cork, Dublin, Edinburgh, Brussels, and Paris. He took the triple qualifications of the Conjoint Board in Scotland in 1891, became F.R.C.P.Ed. in 1911, and graduated M.D.Durh. in 1912. Dr. Barry was a man of exceptional physique, and a fine all-round athlete; an expert in throwing the hammer, he created a "record" in 1895 with 138 ft. 7½ in. He was also well known as an amateur boxer, and at different times held the heavy-weight championships of the U.S.A. and of Australia. About twenty years ago he moved from Southport and joined Dr. A. Jackson of Barry in partnership. He was honorary consulting physician to the Royal Hamadryad Seamen's Hospital, Cardiff, medical examiner at Cardiff for the Shipping Federation, and medical officer of the National Maritime Board for Cardiff. Dr. Barry, who was a member of the Cardiff Division of the British Medical Association, is survived by his widow.

The sudden death on March 19th of Dr. HAROLD TURNER FINLAYSON, in his 37th year, has occasioned deep regret among the residents of Formby, Lancashire, where he had practised for more than ten years. He received his medical education at Aberdeen and St. Mary's Hospital, graduating M.B., Ch.B.Aberd. in 1912. At the outbreak of war he served with the Grand Fleet in the North Sea, and later held a commission in the R.A.M.C. He was clinical assistant in the Royal Southern Hospital, Liverpool, medical officer to Holmewood School and Children's Sanatorium, Freshfield, and to the Church of England Home for Waifs and Strays, Formby. His earlier appointments included those of house-surgeon to the Royal Infirmary, Dundee, casualty officer to St. Mary's Hospital, and surgeon to the Peninsular and Oriental Steam Navigation Company. A colleague writes: Dr. Finlayson was a man of high ideals, and his progressive ability rendered him a greatly trusted medical adviser in a large general practice, which extended far beyond the district in which he resided. His knowledge of some of the more special departments of medicine and surgery was considerable, and he kept himself abreast of everything that was modern in practice by reading and by his work at the Liverpool Royal Southern Hospital, where he had held the post of clinical assistant for over two years. Dr. Finlayson was a genial man, with an alert manner and progressive mind; a great reader, and a lover of music and the arts. His sympathy and kindness were associated with a spirit of self-sacrifice which led him to overtax his strength, and his early death was in some measure related to this fact.

Professor JAMES ISRAEL, formerly director of the surgical department of the Israelite Hospital in Berlin and a well known authority on renal surgery, has recently died at the age of 78. He was a pupil of von Langenbeck and Traube.

Medical News.

SIR THOMAS BARLOW, Bt., M.D., has been elected president of Bolton Infirmary for the ensuing year in succession to the late Lord Leverhulme, who had been president since 1916. Sir Thomas Barlow, who was born at Edgeworth, and spent his early life in the neighbourhood of Bolton, now becomes the first medical president of the Infirmary.

DR. ADAMI, Vice-chancellor of the University of Liverpool, who went to America at the end of last month, expects to return home early in May.

WE have received the first number of the *Malayan Medical Journal and Estate Sanitation*, which is a quarterly record of medicine and surgery, with special reference to tropical medicine and the hygienic management of estates. It is published at Kelantan, Malaya, under the editorship of Drs. T. S. Macaulay, G. B. McHutchison, J. J. Hickey, and W. Thudner. Sir David Galloway contributes the paper on inguinal lymphadenitis which he read at the annual meeting of the Malaya Branch of the British Medical Association, at Kuala Lumpur, in April, 1925, and the issue also includes an original article on the treatment of pneumonia, by Dr. T. S. Macaulay. The remainder of the issue is devoted to local news and general medical and sanitary subjects in Malaya.

THE Bureau of Hygiene and Tropical Diseases has begun the publication of a *Bulletin of Hygiene*, which is to contain summaries and reviews of publications on all branches of public health and preventive medicine. It is intended more particularly to meet the needs of Britain overseas. The section of hygiene in the tropics will deal with publications in various languages, as did the Sanitation Supplements formerly issued by the Bureau, but now discontinued. With this exception the *Bulletin* will for the present be mainly restricted to publications in the English language. Suitable papers and reprints in any language, if sent to the Bureau, will, however, be noticed as far as possible. The *Bulletin* will be published monthly and the annual subscription will be 21s. post free. Orders may be sent to the Bureau of Hygiene and Tropical Medicine, 23, Endsleigh Gardens, London, W.C.1. The contents are classified under various heads, and the last number (March, 1926) contains a review of the present position of public health propaganda and education in Great Britain. The publication of the *Tropical Diseases Bulletin* (21s. a year post free) and of the *Tropical Veterinary Bulletin* (10s. a year post free) will be continued as heretofore.

AT the meeting of the Medico-Legal Society to be held at 11, Chandos Street, Cavendish Square, W.1, on Tuesday, April 20th, at 8.30 p.m., a paper will be read by Mr. C. Ainsworth Mitchell on some aspects of the new regulations on preservatives, which will be followed by a discussion.

THE Home Secretary has appointed Lieut.-Colonel John Allan Anderson, M.B., Ch.B., D.F.H., late R.A.M.C., to be an inspector under the Cruelty to Animals Act, 1876, which relates to experiments on living animals.

THE University of Birmingham Clinical Board has arranged a course of post-graduate demonstrations to be given at the General Hospital on Tuesdays, commencing on April 13th, at 3 p.m., and at the Queen's Hospital on Fridays, commencing April 30th. The course will include demonstrations on medical, surgical, and gynaecological cases, nervous diseases, ophthalmic cases, children's diseases, etc. The fee for the course is £2 2s., which should be sent to the Clerk to the Clinical Board, University, Edmund Street, Birmingham.

THE annual spring dinner of the Queen's (Belfast) University Club, London, will be held at the Connaught Rooms, Great Queen Street, W.C., on Thursday, April 22nd, at 7.30 p.m., under the chairmanship of Dr. R. W. Livingstone, president of the club and vice-chancellor of the university. Further particulars can be obtained from Dr. J. P. Martin, 59, Queen Anne Street, W.1.

THE annual report presented to the meeting of the Mental After-Care Association, held under the presidency of Sir Charles Wakefield on March 16th, showed that during the year 1,431 cases had been dealt with, an increase of 255 over the previous year. Dr. R. Percy Smith, in presenting the report, said that the value of the work of the association to the community could not be too strongly emphasized, as it enabled medical superintendents to discharge recovered patients at an earlier date than would otherwise be possible. The tendency to relapse was thereby greatly diminished, inasmuch as patients were able to consolidate their recovery in the cottage homes provided by the association. It was announced that Sir Charles Wakefield had expressed his intention to wipe out the whole of the overdraft of the association, which amounted to £517.

THE People's League of Health, being engaged in an educational health and food campaign, recently asked the General Medical Council to express an opinion on the question whether medical officers of health who, at the request of their municipal authorities, compiled and published educational health and food leaflets ran any risk of infringing the warning notices of the General Medical Council. The Registrar has replied that publication in the press of articles on medical subjects by medical practitioners has not been condemned by the Council unless it has been proved that the articles come under the terms of the Warning Notice (published June, 1923) or are otherwise objectionable; and that medical officers of health publishing and circulating in their districts information about health and food at the request of the municipal authorities or local health councils need therefore have no fear that this action performed officially and in good faith will be censured by the General Medical Council. This is in accordance with the statement as to the procedure of the General Medical Council mentioned in the memorandum published in the SUPPLEMENT of March 20th (p. 96). The passage in the memorandum referred to will be found on page 99.

THE staff of the Brownlow Hill Infirmary, Liverpool, has presented Dr. Ernest Nevins with a Chippendale cabinet and other gifts on his retirement from the post of visiting physician after twenty-six years' service.

ON the occasion of his retirement from practice at Cromer Dr. Robert Grant has been presented by his friends and patients with a gift of £545.

THE London County Council recently decided to increase by one the number of positions of senior medical officer in its public health department. Sixty-seven applications were received in response to public advertisement. The Establishment Committee, after interviewing several of the applicants, recommended the appointment of Dr. Aubrey Middleton Hewat, medical officer of health and administrative tuberculosis officer for Fulham, and the Council agreed to Dr. Hewat's appointment. The salary attaching to the post is £1,000, rising by £50 annually to £1,300 a year. This, however, is based on pre-war conditions, and the temporary additions make the nominal salary of £1,000 actually £1,234 at the present time.

DURING 1925 the total number of patients under treatment at the London Fever Hospital was 899, of whom 682 were fever cases and 217 had pulmonary tuberculosis. There was a diminution of 103 in the number of fever patients under treatment during the year, as compared with the previous twelve months, owing to a fall in the number of cases of measles. At the annual general meeting of the governors of the hospital on February 24th it was pointed out that there had been no case of cross infection—a high testimony to the efficiency of the institution. The number of private patients received during the year was nearly 200. Lord Ebury, the president of the hospital, drew attention to the fact that the ordinary income had increased by £3,187, and the extraordinary income by £1,234, the latter being derived from legacies; the overdraft at the bank had been reduced by £1,500, and amounted to £3,500.

THE number of cremations at the sixteen British crematoriums last year was 2,701, showing an increase of 306 as compared with the previous year. Of these 1,553 were performed at the four Greater London crematoriums at Golders Green, Ilford, Norwood, and Hendon Park, and 271 at Woking. Additional accommodation is being provided at Golders Green, where the limit of working capacity under existing conditions was reached last year. It is pointed out in the annual report for 1925 of the council of the Crematorium Society of England that municipal crematoriums are in most cases self-supporting, even if they do not produce the substantial revenue obtained by the crematoriums owned by private companies; they do not involve any expense to the community, in contrast with earth burial under ordinary conditions.

THE well known psychiatrist, Professor Emil Kraepelin, has recently celebrated his seventieth birthday.

DR. JEAN CHARCOT, the explorer, and son of the neurologist, has been elected a member of the Académie des Sciences.

THE forty-first congress of the German Balneological Society is being held at Aix-la-Chapelle from April 6th to 11th. The principal subjects for discussion are the balneotherapy of diseases of the joints and muscles and the indications for sulphur baths.

MESSRS. J. AND A. CHURCHILL announce for early publication: *The Chemistry of the Proteins*, by Dr. Dorothy Jordan Lloyd; *Recent Advances in Biochemistry*, by Dr. John Pryde of the Physiology Department, University College, Cardiff; the fourth edition of Sir Maurice Craig's *Psychological Medicine*, in which Dr. T. Beaton has collaborated; and a new edition of Dr. M. Dobbie's translation of Arvedson's work on *Medical Gymnastics and Massage in General Practice*.

MR. HENRY KIMPTON announces for early publication: *The Principles and Practice of Endocrine Medicine*, by William Nathaniel Berkeley, M.D.; *A Descriptive Atlas of Visceral Radiograms*, by A. P. Bertwistle, M.B., F.R.C.S.E., and E. W. H. Shenton, M.R.C.S., L.R.C.P.; *A Handbook of Diseases of the Rectum*, by Professor Louis J. Hirschman, M.D.; and *Modern Methods of Amputation*, by Professor Thomas G. Orr, M.D.

THE March issue of *The Industrial Chemist* contains an account of the chemistry and applicability of microscopic stains. In addition to the chemical composition and indications for use of the more common dyes after tissues have been fixed, the process of *intra vitam* staining is considered. Free reprints of the article may be obtained from the editor at 33, Tothill Street, S.W.1.

WE have received a copy of *L'Oto-rhino-laryngologie Chirurgicale*, which is a special number issued by the *Strasbourg Médical*, a journal founded under the name of the *Gazette médicale de Strasbourg* in 1843. This number, which is edited by Professor G. Canyot, who holds the chair of oto-rhino-laryngology at Strasbourg University, contains, among others, original articles by Professor J. Moutet of Montpellier on the importance of anatomy in oto-rhino-laryngology, by Dr. L. Dufourneubel of Paris on methods of general anaesthesia in cervico-facial surgery, by Dr. Jean La Barre of Brussels on the causes of haemorrhage, and Professor Canyot's inaugural address.

A POST-GRADUATE vacation course dealing generally with tuberculosis and Alpine climate (the third of its kind) will be held at Davos from August 22nd to 27th. The programme will comprise lectures and demonstrations by the medical men of Davos on the climatology, pathology, diagnosis, and prognosis of tuberculosis. The lectures are given chiefly in the French and German languages, but arrangements are being made this year for certain lectures and demonstrations in English. It is hoped that many English medical men will avail themselves of this opportunity of seeing Davos and making themselves acquainted with the work done there. Information and assistance in regard to the course will be given by Dr. Bernard Hudson, Victoria Sanatorium, Davos-Platz.

MR. GEORGE BLUMENTHAL of New York has presented 60,000 dollars to the Assistance Publique of Paris for the construction of an oto-rhino-laryngological pavilion at the Hôpital des Enfants Malades.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **THE EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the **BRITISH MEDICAL JOURNAL** alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the **BRITISH MEDICAL JOURNAL** must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the **JOURNAL**, should be addressed to the Financial Secretary and Business Manager.

THE TELEPHONE NUMBERS of the British Medical Association and the **BRITISH MEDICAL JOURNAL** are **MUSEUM 2861, 2862, 2863, and 2864** (internal exchange, four lines).

THE TELEGRAPHIC ADDRESSES are:

EDITOR of the **BRITISH MEDICAL JOURNAL**, *Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Mediscen Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 4757 Dublin), and of the Scottish Office, 6, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 4361 Central).

QUERIES AND ANSWERS.

ALPINE "SNEAKERS."

DR. CLAUDE WILSON (Tunbridge Wells), a former vice-president of the Alpine Club, writes with reference to the inquiry of "A.R." on March 20th (p. 554) for information about the prevention of sunburns in the higher Alps. He states that the late Dr. Bowles of Folkestone and London was the first to notice that people who freckled became sunburnt between the freckles and not on them. He therefore painted the faces of blonde girls who ascended the Schilthorn from Mürren with a yellowish-brown pigment, and found that they did not burn. These experiments were

made in the eighties. In 1898 Dr. Sechehaye of Geneva, while experimenting with x rays, discovered a yellow substance which was particularly opaque, and with it he prepared a skin cream, which is stated to be an efficient prophylactic against Alpine sunburn and also sunstroke. It is dispensed in convenient collapsible tubes under the title of "Pomade du Dr. Sechehaye" by the Pharmacie Haussier, 10, Bourg-de-Four, Geneva, price 2.50 (Swiss) francs. With regard to treatment, Dr. Wilson says that hot-water sponging, followed by a bland powder ("psma" is said to be one of the best), and then by an application of vaseline, when the skin becomes dry, will relieve the pain and cure the dermatitis within two or three days.

"STATIC ALBUMINURIA."

"L.R.C.S.ED., X.Y.Z." writes: In the BRITISH MEDICAL JOURNAL of April 3rd "F.R.C.P." asks advice as to the cure of "static albuminuria." I hesitate to tackle the subject, as in the Editor's opinion it seems, so far, to have merited only four lines of small type. I think it is impossible even for an editor to deal with the matter in such brevity. I prefer the term "orthostatic," as the albuminuria chiefly occurs when the patient assumes the erect posture. Prolonged rest, which he says cures for a time, is most certainly not the best treatment. "F.R.C.P." says that he can find very little literature on the subject, but if he cares to overhaul the volumes of the BRITISH MEDICAL JOURNAL for the last forty years he will discover a good deal of writing, wise and otherwise—mostly otherwise—on this disturbance. It must be nearly forty years since I heard the late Dr. Pavy deal with this trouble at an Annual Meeting of the British Medical Association in, what then seemed to me, a rather perfunctory manner. It has been described under various titles, such as static, orthostatic, and, not infrequently, as the albuminuria of adolescence, which is about as sensible, or as stupid, whichever way you choose to look at it, as the so-called juvenile pulse. It is also frequently styled neurasthenia by those who do not trouble to examine the urine. This condition is associated with defective vasomotor tone in the splanchnic area, and comes within the late Albert Abrams's category of cardio-splanchnic paresis. When the patient is recumbent the blood pressure is low and there is an even distribution of blood throughout the body, but once the erect posture is assumed there is not sufficient response in the splanchnic area to raise the pressure; the patient looks pallid and may even feel faint for a short time, but quickly the reciprocal action of the vasomotor system in the peripheral vessels comes into play, the arterioles and arteries become firmly contracted, and the pressure is raised. The paresis of the parasympathetic in the splanchnic area remains and the abdominal organs are congested.

I would recommend "F.R.C.P." to read that excellent little book by Dr. Langdon Brown on the *Sympathetic Nervous Systems in Disease*, and he might peruse with advantage the best lecture which has appeared in the BRITISH MEDICAL JOURNAL this year—that by Professor John Fraser (February 27th) on disturbances of the involuntary nervous system met with in the alimentary tract. He will then be in a position to study the monumental work of Albert Abrams on spondylotherapy, which deals with all the spinal reflexes.

Having now put "F.R.C.P." in the way of acquiring all necessary information, I shall briefly summarize my own method of treatment. A long night's rest in the recumbent posture. During the day wear tightly an elastic abdominal belt, plenty of exercise, especially hill climbing, which induces deep breathing. A plain, liberal diet—beef, mutton, chicken, fish, vegetables, milk puddings, and milk in moderation; not much slops of any kind. Too free a use of decalcifying agents even in health may bring on temporary albuminuria; it is, therefore, well to avoid acids, acid fruits, sweets, and much starchy food. Lime is essential, but it should be prescribed in moderation, as too much is apt to depress the peristaltic action of the bowel. Moreover, it is only absorbed as an oleate, so I find it best to prescribe one large dose at bedtime, along with one or two tablespoonfuls of cod-liver oil or olive oil; pilocarpine, which has a synergic action to the parasympathetic, is useful in small doses. The best purgative, in my opinion, is the acid phosphate of sodium, which stimulates peristalsis, and the *Bacillus coli* does not seem to flourish in its presence, as the offensive odour of the faeces disappears. To those acquainted with the spinal reflexes I would recommend concussion of the eighth and second dorsal spines two or three times daily.

LETTERS, NOTES, ETC.

IMPREGNATIO MULIERIS ARTIFICIOSA.

WE have received from a general practitioner of great experience (who for obvious reasons prefers to be anonymous) the following note, which we agree with him in considering of general interest from more than one point of view:

In early childhood XY, now aged 35, had had an operation performed on him for extroversion of the bladder, the ureters and seminal ducts being turned into the rectum. The operation was very successful, and in time he was able to hold his water for about five hours. At the age of 30 he married, his wife being fully cognizant of his infirmity. After five years both she and he were intensely desirous of having a child, and inquired whether it was possible to attain this object artificially. On examination he was found to be a strong man of excellent physique and in perfect health. There is a firm triangular scar in the pubic region, the penis being grooved on its dorsal aspect, a deeper sulcus partially dividing the glans. The testicles are

well developed, firm, and healthy. The semen was found healthy, with a proper proportion of living spermatozoa. After discussion it was decided that in the circumstances it was justifiable to make the attempt, the difficulties being fully appreciated. He was directed thoroughly to wash out and cleanse the rectum with hot soap and water, and then to inject a small quantity of a solution of sodium bicarbonate (gr. v to the ounce), part of which might be retained with the object of neutralizing any very acid urine which might ooze into the bowel. Directly after intercourse the semen was voided into a warmed cup and with the least possible delay injected high up into the vagina but not actually into the os uteri. This was done a day before the onset of an expected period, and again on the sixth and seventh days from the commencement of the period. Three times there was no result, but the fourth time impregnation took place and a perfect and healthy child was born 276 days from the date of the premenstrual injection, or 270 days from the date of that done on the sixth day after the commencement of the period.

LIGHTNING AND FORKED LIGHTNING.

DR. G. C. SIMPSON, F.R.S., Director of the Meteorological Office, communicated to a recent meeting of the Royal Society his results of an investigation of the discharge of electricity through clouds. His conclusions drawn were: The conducting medium originates in the region of maximum humidity only in the direction of the seat of negative electricity. A negatively charged cloud can only be discharged by a discharge originating in a positively charged cloud, or in the induced positive charge on the earth's surface. A positively charged cloud may be discharged by discharges starting in the cloud and terminating either in the surrounding air or on the earth's surface. If a lightning flash is branched the branches are always directed towards the seat of negative electricity. The application of these conclusions to 442 photographs of lightning discharges reveals the fact that the majority of lower clouds from which discharges proceed are positively charged.

ACTINOMYCOSIS SUCCESSFULLY TREATED BY IODINE IN MILK.

MR. W. D. (a medical student), writes: I have read with some interest the article of March 6th (p. 418) by Mr. H. J. (a medical student) on the successful treatment of actinomycosis by iodine in milk. We have used iodine in milk as more or less of a specific in the treatment of actinomycosis. I have used it with liq. donovani or of hyd. iod. solution of potass. iod. content of the one and mercurial of the other has any contributory effect or not I am unable to say categorically, although the antiparasitic and penetrating action of both might well be of assistance. Generally speaking, the improvement is most usually met with—namely, in the tongue, with its invasions of the jaw and facial bones—is nothing short of marvellous, even if of long-standing and malignant degree. Given in fairly heroic doses, I administer either only in a little cold water, and being both odourless and tasteless the administration is easy. Their colloidal exhibition in milk might be an improvement, and at the first opportunity I will give the iodine as recommended by Mr. Chitty a trial, either in the form of tincture or Lugol's solution, and will compare the results.

ANOTHER UNUSUAL PRESENTATION.

DR. W. B. HUNTER (Londonderry) writes, with reference to Dr. D. J. Malan's report (March 13th, p. 476) of a case of unusual presentation, to describe a somewhat similar experience many years ago. Dr. Hunter on his first examination of the patient found that the membranes had ruptured previously and spontaneously and that a foot was lying in front of the head. He was able to trace the sole of the foot from the heel to the toes, and concluded that he had to deal with a twin pregnancy. On making an attempt to push the foot up and out of the way he discovered that the obstruction had been born soon afterwards. Examination of the child showed that such was present. Dr. Hunter then succeeded in placing the foot of the child on to its head in the position discovered at his first examination. He states that the baby was lively and the joints of the leg did not seem to be abnormal, except perhaps that they were rather more mobile than usual. He adds that Dr. Matthews Duncan, then living in Edinburgh, said that such a case was uncommon but not unknown.

CORRECTION.

DR. FREDERICK HEAF (King Edward VII Memorial Sanatorium, Hertford Hill, near Warwick) asks that an error in the last issue of the JOURNAL be corrected. In the paragraph under the heading "Sancrocylin" (p. 630) his remarks were attributed to "Dr. Heath." The mistake was due to a clerical error.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 41, 42, 43, 45, and 47 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 44 and 45.

A short summary of vacant posts notified in the advertisement columns appears in the Supplement at page 120.

An Experimental Investigation INTO THE ETIOLOGY OF ACCIDENTAL HAEMORRHAGE AND PLACENTAL INFARCTION.*

(Preliminary Communication.)

BY

FRANCIS J. BROWNE, M.D. ABERD., D.Sc., F.R.C.S. Ed.,
ASSISTANT PHYSICIAN, EDINBURGH ROYAL MATERNITY AND SIMPSON
MEMORIAL HOSPITAL.

(Working for the Medical Research Council.)

(With Special Plate.)

In spite of much research work within recent years comparatively little has been discovered concerning the causation of accidental haemorrhage. Most writers, including Gordon Ley¹ and Whitridge Williams,² have agreed in ascribing it to toxæmia of pregnancy, while others, led by James Young of Edinburgh, have looked upon the toxæmia as secondary to and consequent upon the haemorrhage. According to Young³ the placenta separated by haemorrhage undergoes necrosis, and during the early stages of the necrosis autolytic products are absorbed into the circulation through the portion of placenta still attached to the uterine wall. These products, acting upon the maternal organs, especially kidneys and liver, set up the changes commonly associated with the toxæmias of pregnancy. The cause of the haemorrhage Young and his followers leave undetermined, but they suggest that it may be ascribed to a primary thrombosis of unknown origin in the veins of the broad ligament or uterus causing engorgement and rupture of the veins of the decidua and uterine wall. It is true that frequently, in cases of concealed haemorrhage, thrombi are found in the ovarian veins; but seeing how free is the anastomosis between the various veins that drain the uterus, it has always seemed to me difficult to believe that this thrombosis, unless it occurred suddenly and involved all the venous drainage of the uterus, could produce haemorrhage even in an organ so vascular as the pregnant uterus. Morse,⁴ for example, found that he could not produce haemorrhage in the uterus of the pregnant rabbit unless he ligatured all the veins—namely, the ovarian, mesometrial, and utero-vaginal—going off from one cornu. If all the veins were ligatured intense utero-placental apoplexy was produced, the uterine wall being ploughed up by the blood. Obviously nothing else can happen in such a vascular organ if all the veins are ligatured, and Morse himself attaches no clinical importance to this experiment. I hope to prove in this paper that the thrombosis is the result of the toxæmia, not its cause. Morse also produced haemorrhage by extreme rotation of the uterus on its long axis. From the latter experiment he argued that torsion of the uterus is a cause of accidental haemorrhage, and especially of utero-placental apoplexy. Whitridge Williams,² in a recent review of the subject, has expressed his scepticism regarding the importance of uterine torsion as a cause, and writes as follows:

"Since the appearance of his [Morse's] paper we have been careful to note the position of the uterus whenever the abdomen is opened, but in none of our patients treated by Caesarean section did the uterus present evidence of being markedly twisted upon its vertical axis. It is true that Polak has reported and pictured an instance in which such torsion had occurred that the Caesarean incision lay in the neighbourhood of the insertion of the left round ligament, but so far as I am aware it is the only evidence that has been adduced in support of Morse's contention."

From my own experience of Caesarean section I can say that I have more than once found a degree of rotation towards the right, almost as marked, without any evidence of haemorrhage. Trauma has also been invoked as a cause. Certainly a definite history of trauma can be obtained in some cases, but the association is probably coincidental.

ORIGIN OF THIS INVESTIGATION.

In September, 1923, while working in collaboration with Dr. W. R. Logan, clinical bacteriologist, Edinburgh Royal Infirmary, on the paths of intranatal infection in the newly born infant, we had injected a healthy rabbit, twenty days pregnant, with an emulsion of *Bacillus pyocyaneus* in saline. Six hours after injection we found the rabbit bleeding profusely from the vagina. On being removed from its cage to the experimental room the bleeding continued, about 3 drachms of blood being lost on the table in a few minutes. Under ether anaesthesia the abdomen was opened and the left pregnant horn exposed. On opening the lowest sac a recently dead foetus was found, and a retroplacental clot entirely or almost entirely separating the placenta (Fig. 1). The foetus with its placenta and adherent clot was removed and preserved. The other sacs (there were four in each horn) contained normal living foetuses and showed no evidence of haemorrhage. The empty sac from which bleeding had occurred was immediately placed in Pick's solution, together with pieces of the mother's liver and kidneys.

Microscopic examination of the sac wall (uterine wall) in relation to which the retroplacental haemorrhage had occurred showed well marked oedema throughout which widely separated the muscle bundles. In the mucosa of the placental site, adjacent to the zone of separation, there was well marked blood extravasation, and at one part the extravasated mass lay in relation to a ruptured maternal capillary, about one-third of the wall of which was more or less completely destroyed. No haemorrhage was observed in the muscular wall of the uterus. The kidney showed acute congestion of the glomerular and intertubular capillaries. The glomeruli were congested, but otherwise healthy. There was acute parenchymatous nephritis, shown by cloudy swelling of the epithelium of the convoluted tubules, so that the latter seemed in many places blocked by the epithelial swelling (Fig. 2). The epithelium of the straight tubules appeared fairly normal. No actual necrosis was observed, and no haemorrhage or thrombosis. There was also present in the kidney a certain amount of old interstitial change. The liver showed round-cell infiltration of the portal tracts and fatty change in the liver cells. The latter, however, is probably a fairly common finding in the normal liver of the rabbit, and we attached no significance to it. There was no thrombosis nor focal necrosis.

Realizing the importance of this result we made numerous attempts to repeat the result in pregnant rabbits, using various organisms and other substances by intravenous injection. In all, 34 experiments were carried out for this purpose subsequent to the success of September, 1923, the materials used being as follows: *B. pyocyaneus* (9 cases); *B. coli* (4); *streptococcus* (1); *B. mesentericus* (1); *B. typhosus* (2); *B. paratyphosus* (2); saline solution (4); *Staphylococcus aureus* (1); pneumococcus (3); histamine (4); ricin (2); toxins obtained by putrefying meat for three weeks and filtering through a Berkefeld filter—injected on three successive days (1). Many of the series died in twenty-four to forty-eight hours after injection, while a few aborted, but in none of the thirty-four did any haemorrhage occur except once, immediately after a histamine injection. Immediately after injection bleeding started, followed by abortion on the operating table. The three other histamine rabbits also aborted, two of them without any haemorrhage, while in the other a slight haemorrhage occurred. As slight haemorrhage at the time of littering is usual in the rabbit we discounted this.

These experiments were concluded in May, 1925, and had ended in almost complete failure to reproduce the first and only success (of September 8th, 1923). There was evidently some factor essential for success that we had so far failed to recognize. Up till this time I had looked on the nephritis not as a predisposing cause of the haemorrhage, but on the nephritis and the haemorrhage as both being due to the same cause—namely, toxæmia—and both as end-results of the toxæmia.

At this stage Dr. Logan withdrew from the investigation as the experimental portion (on the paths of intranatal infection) had been concluded, and the present work seemed to have little or no bacteriological bearing.

* Read at a meeting of the Edinburgh Obstetrical Society, March 10th, 1925.

During the time that the above negative experiments were going on, being interested in the subject of accidental haemorrhage, I had personally been taking very careful notes of all the cases seen in the Royal Maternity Hospital and in private practice, and began to be impressed by the frequency with which I could obtain a history of nephritis or of albuminuria in pregnancies preceding that in which accidental haemorrhage had occurred. But, with one exception, none of these cases had been followed up in the intervals between pregnancies, so it was impossible to say with certainty whether the nephritis accompanying the haemorrhage had preceded or followed the placental separation. In one case, however, the evidence was clear, for I had got the patient back in the interval between pregnancies for examination of kidney function.

The woman was an 11-para; first nine children alive and well; the ninth was born in 1921, the tenth (macerated) in 1922. On July 28th, 1924 (twelfth pregnancy), she was admitted with accidental haemorrhage and albuminuria. The same day she was delivered of a premature stillborn foetus. On leaving hospital her urine contained a trace of albumin; blood pressure normal. On November 10th the urine still contained 1 per cent. of albumin, and on February 15th, 1925, it contained 0.07 per cent.

During her stay in hospital her urea concentration was estimated twice, the highest concentration obtained being 1.8 per cent.; blood urea=43 mg. per cent., non-protein nitrogen 38 mg. per cent. At the visit on February 15th, 1925, she was again three months pregnant. In May she was admitted with concealed haemorrhage, albuminous urine, and a tense and ligneous uterus. She was treated conservatively by rupture of membranes and pituitary extract, and a 7 months dead foetus was delivered. On discharge from hospital there was still albuminuria.

These cases induced me to believe that nephritis was an important predisposing cause of accidental haemorrhage,

and I decided to make attempts to produce nephritis in animals, and then in those animals in which nephritis had been set up to introduce toxins. If my theory were correct I should then be able to cause accidental haemorrhage.

EXPERIMENTAL NEPHRITIS.

Prior to 1924 we had no even moderately certain method of producing nephritis, either acute or chronic, but in that year were published two important papers³ by Shaw Dunn, Haworth, and Jones of Manchester on oxalate nephritis, which showed that it was possible, by injecting oxalates into rabbits, to produce in them the lesions of acute parenchymatous nephritis. In November, 1925, I therefore stocked 34 female rabbits and began attempts to produce kidney lesions according to the method of Shaw Dunn, Haworth, and Jones, with some slight modifications.

Method.

Sodium oxalate was used throughout in 1 per cent. solution. The rabbits were weighed each morning before injection and drawing off blood, and 50 mg. per kilo of body weight, or a dose as nearly as possible approximating this, was injected into the ear vein. This was repeated at varying intervals, depending upon the effect produced. Blood was drawn off also at varying intervals and the blood urea estimated, using a modification of Marshall's urease method and 1 c.cm. of whole blood for each estimation, with frequent controls by standard urea solutions. The blood urea was taken as the clinical index of the onset and duration of the nephritis. The results obtained in three typical cases are shown in Table I.

Note.—Rabbit B 8 had full-time young on January 25th; they were dead when found; there was no haemorrhage. On February 25th it was twenty days pregnant again. On March 2nd it had several haemorrhages at 9 a.m. On March 3rd it had profuse haemorrhage at 12.15 p.m.; killed at 5 p.m.

Three of the rabbits were kept in urine cages and twenty-four hour specimens of urine collected, measured, and tested for albumin daily, and the urea concentration estimated.

Note (1) the fall in the urea concentration to 14 on January 25th; (2) the absence of albumin in the urine on that day, when the blood urea reached 128 mg. per cent., and at no time was more than a trace present.

As the ultimate object of the research was the production of accidental haemorrhage, and not the study of nephritis, I merely wanted to be sure that I had produced nephritis, and therefore paid less attention than I otherwise might to the many fascinating physiological and pathological questions involved in the experiments. Two points, however, deserve special notice:

(a) The very rapid rise in the blood urea. After injection with oxalate this not infrequently rose in a few hours to a very high figure (for example in rabbit B11 (see Table I) the blood urea rose in twenty-four hours after injection of 9 c.cm. of oxalate from 54 to 218 mg. per cent.), and would almost as rapidly drop from this high figure to normal.

(b) Even in cases in which the blood urea was at a high figure and in which, therefore, there was an acute nephritis present, albumin might be entirely absent (see rabbit B33 in Table II, in which on January 25th the blood urea was 128 mg. per cent. and yet the urine was albumin-free). This is a point of great clinical importance and will be referred to later.

The work on nephritis was continued throughout November, December, and January, and on February 1st it was stopped and the rabbits mated. At this time I was left with 26 rabbits, 8 having died from various causes connected with the experiments (overdosage, etc.), and in practically all of these 26 I had obtained evidence of the production of nephritis by a rise in the blood urea at some time or other during the course of the work. From histological examination of the kidneys of several of the series I now know that I had produced very well marked early interstitial nephritis as well.

General Account of the Kidney Lesions.

Generally speaking the kidneys appeared enlarged, congested, and oedematous, but in none of my cases so far examined have haemorrhagic lesions been produced. The

capsule stripped easily, even in those that had been killed most recently and which had therefore suffered from nephritis for about three months.

Rabbit B12 may be described as fairly typical of the kidneys so far examined. This animal had been under treatment from November 10th, 1925, till January 26th, 1926, when it died in a convulsion immediately after an injection of oxalate. Its blood urea on January 4th had reached 141 mg. per cent., but at the time of death had fallen to normal, the urea in the heart blood being 30 mg. per cent. The kidneys were congested, but there were no haemorrhages and the capsule stripped easily. Microscopically (Figs. 3 and 4) the glomeruli were swollen and congested, but there was no exudate in the capsular spaces. Cloudy swelling was present in many of the convoluted tubules, but this change was not universal, and was most marked in the first convoluted tubules. Some tubules were dilated and filled with secretion. There was well marked early interstitial change and oedema in the cortex, best marked among the small collecting tubules.

Rabbit B9 had been under treatment from November 10th till January 10th, when it was found dead in its cage. It had previously become much emaciated. Its blood urea had been, at the last estimation, two days before death, 227 mg. per cent., its normal being 26. The convoluted tubules showed marked cloudy swelling and necrosis so that the lumina were almost closed. Some highly refractile fatty granules were present in the cells and some in the lumina of the tubules (Figs. 5 and 6). Some nuclei were pyknotic, others undergoing karyorrhexis or karyolysis. Well marked early interstitial change was present throughout the cortex, and here and there in the newly formed interstitial tissue were deposits of lime salts, probably calcium oxalate. It may be assumed that these originally lay in the tubules that had undergone necrosis, and that they had, as it were, become stranded in the newly formed interstitial tissue.

PRODUCTION OF ACCIDENTAL HAEMORRHAGE.

I decided that on the twentieth day of pregnancy (the duration of pregnancy in the rabbit is thirty days) I would make attempts to produce accidental haemorrhage. Twenty days would correspond to the sixth month in the human subject, a time when accidental haemorrhage frequently occurs.

Rabbit B7 reached the twentieth day on February 23rd, 1925. It had been under treatment from November 10th, 1925, to January 30th, 1925. Its blood urea, however, had never reached a very high figure, the highest being 102 mg. per cent. on January 27th. By January 30th the blood urea had again fallen to normal—namely, 25 mg. per cent.

On February 23rd, at 12 noon, 8 c.cm. of sodium oxalate were administered intravenously. The animal was placed in a cage with clean cotton-wool in the bottom, and was watched constantly. The next day, at 9 a.m., a haemorrhage had occurred. Two parts of the cotton-wool were stained, and the total amount was estimated at about 2 drachms. The rabbit was still pregnant. Blood urea was estimated at 12 noon, and was 79 mg. per cent. At 12 noon 3 c.cm. of oxalate were given plus 1 c.cm. of emulsion of *B. pyocyaneus* in saline. At 1 p.m. two fresh haemorrhages occurred, at 7 p.m. a third, and at 7.30 p.m. it was killed by chloroform. Three foetuses were in the right horn and two in the left. The cornua were removed and placed in fixative. On sectioning the placentas *in situ* after fixation several were found to contain what looked like infarcted areas, but they have not been examined microscopically.

Rabbit B24. This animal had been under treatment by oxalates from November 11th, 1925, till February 2nd, 1926. Its blood urea had risen from a normal level of 25 to 120 mg. per cent. on December 30th. On February 2nd it was still 73.

On February 21st it was twenty days pregnant; 7 c.cm. of oxalate were given at 11 a.m. No haemorrhage occurred all that day. The following day the blood urea = 98 mg. per cent.; 2 c.cm. of oxalate plus 1 c.cm. of *B. pyocyaneus* emulsion were given at 12 noon. No haemorrhage occurred during the day.

The first haemorrhage occurred at 9.45 a.m. on February 25th. The cotton-wool on the floor of the cage was half an inch thick, and was soaked through; the stain measured 3/4 by 1 1/2 in., and the amount of blood lost was therefore estimated at half a drachm. At 12 noon she aborted two foetuses, which seemed to have been dead for one or two days. She was examined at 12.15 p.m. and found still pregnant. Another large haemorrhage had occurred in the last quarter of an hour, but no further abortion. At 1 p.m. a further large haemorrhage occurred. The animal was killed by chloroform. Just before killing it aborted two more foetuses and one placenta. At *post-mortem* examination the uterus was found to contain three foetuses still.

Rabbit B31 had been under treatment by oxalates from December 11th, 1925, till January 27th, 1926. Blood urea = 107 mg. per cent. on January 4th, but on February 2nd had fallen to normal again (30 mg. per cent.).

No bleeding had occurred before February 26th. At 12.45 p.m. on this day the blood urea estimation = 103 mg. per cent.; 3.5 c.cm. of sodium oxalate were given plus 1.5 c.cm. of *B. pyocyaneus* emulsion. At 2.30 about half a teaspoonful of blood passed. No further haemorrhage occurred, and on examination on March 1st it was found to have aborted without haemorrhage and eaten foetuses.

Rabbit B28 had been under treatment with oxalates from November 24th, 1925, till the end of January, 1926. The blood urea had never reached a high figure, the highest being 81 mg. per cent. on January 21st.

On March 1st the animal was twenty days pregnant. Sodium oxalate 7.5 c.cm. was given intravenously. The next day at 9.30 a.m. it discharged half a drachm of blood. At 11.45 a.m. 1.5 c.cm. of *B. pyocyaneus* emulsion was injected intravenously; the blood urea was now 124 mg. per cent. No further haemorrhage occurred all this day.

At 9 a.m. on March 3rd about 2 drachms of blood had just been passed. The rabbit was still pregnant. At 8 p.m. a fresh bleeding occurred—about 1 drachm. At 12 noon the next day another haemorrhage occurred; there was no abortion, but the foetuses were getting smaller during the last two days and were probably dead. On March 6th a fresh bright red haemorrhage occurred, about half a drachm.

The animal was killed by chloroform on March 8th at 4.30 p.m. The foetuses in the sacs were almost entirely absorbed, only a putty-like material remaining.

PLACENTAL INFARCTION.

Rabbit B30 (see Table I for details of preparatory treatment.)

On February 25th the animal was twenty days pregnant. At 11 a.m. 8 c.cm. of oxalate were injected. No haemorrhage occurred all this day. The next day, at 12.45 p.m., the blood urea=78 mg. per cent. Sodium oxalate 3 c.cm. plus 1.5 c.cm. of *B. pyocyaneus* emulsion was given intravenously. At 3.30 p.m. it was dull and not eating food, but no haemorrhage had occurred. At 4.45 p.m. a spot of fresh blood passed. At 5.45 p.m. it discharged about half a drachm of blood. There was no further haemorrhage that day.

At 9 a.m. on February 27th the animal aborted one fresh foetus. At 9.35 it discharged more fresh blood, and again at 10.4 a.m.—about half a drachm each time. It was killed by chloroform at 11.30 a.m. One foetus was expelled from the cornu by peristaltic contractions after excision of the uterus, and the foetus in the sac above was partly expelled. The cornua still contained several foetuses. They were fixed immediately in formalin solution. The kidneys seemed to be enlarged, congested, and oedematous.

On March 2nd all the sacs were examined by sectioning with a sharp scalpel, cutting through the foetus transversely and across the placenta and its attachment to the cornu. All the placentas were found to contain numerous thrombi and infarcted areas (three typical ones are shown in Figs. 7, 8, and 9). The foetuses still *in situ* were macerated, but not very markedly so, and had apparently been dead for about two days, the time probably varying somewhat in each individual case. Between the membranes and the uterine wall in one of the sacs there was a haematoma of exactly the size seen in the accompanying figure (Fig. 7). The placental tissue surrounding and between the thrombi was of a firm and liverish consistence, quite different from normal spongy placental tissue. In two cases the uterine wall underneath the placental site was seen to contain blood (Figs. 8 and 9).

Microscopically the infarcted placenta presented all the appearances familiar to us in recent infarcts of the human placenta (Figs. 10 and 11). The villi contained enormously dilated and engorged capillaries. So closely packed were the villi that the intervillous channels seemed to be almost entirely obliterated, and indeed were only visible here and there as slits between the villi. This appeared to be due to the great distension of the foetal capillaries, but was also probably due, as Eden² has shown in the case of the human placenta, to the fact that the thrombus had cut off the supply of maternal blood from the intervillous spaces and thus allowed the villi to fall together. Throughout the fibromuscular wall of the uterus there were several haemorrhages easily evident in most of the sacs to the naked eye. Microscopically these haemorrhages were found to lie amongst the muscle fibres (Figs. 12 and 13), and could in most cases be traced to capillaries the walls of which seemed to have given way. A plasma-like fluid also present amongst the muscle fibres gave the appearance of oedema (Fig. 12).

Rabbit B8—twenty days pregnant (see Table I)—received on February 26th 10 c.cm. of oxalate intravenously; the blood urea at time of injection=64 mg. per cent. No haemorrhage occurred all day. The next day 4 c.cm. of oxalate plus 1.5 c.cm. of *B. pyocyaneus* emulsion were injected. On March 1st 9 c.cm. of oxalate was given; the blood urea then was 73 mg. per cent. A few drops of blood were found at 9 a.m. on March 2nd. At 9.10 there was a discharge of about 1/2 c.cm. At 11.20 a.m. 1.5 c.cm. of *B. pyocyaneus* emulsion was injected. The blood urea was 56 mg. per cent. At 12.15 p.m. a further profuse haemorrhage occurred. The animal was killed by chloroform at 5 p.m. The heart blood urea=116 mg. per cent. Urine obtained from the bladder contained no trace of albumin (Heller's test). The kidneys were large, congested, and oedematous. Each uterine sac contained a mass of material resembling hydatidiform mole, which has not so far been examined microscopically. The urine obtained from the bladder at post-mortem examination contained no trace of albumin (Heller).

At this stage therefore I had attempted to produce accidental haemorrhage in six animals and in all the attempts had been successful. There had been produced external accidental haemorrhage, concealed haemorrhage, including haemorrhage in the uterine wall, and placental infarction. There seemed, therefore, to be no further object in continuing this particular experiment, especially as it was seriously depleting my stock of nephritic animals.

EVIDENCE UPON SPECIAL POINTS.

In the time that has elapsed since the experiments above described I have tried to obtain evidence upon certain matters arising in the course of the work.

1. Is a chronic nephritis necessary as a predisposing cause of the haemorrhage? It seems that it is not, and that an acute nephritis may be sufficient. The first successful experiment in 1923 is proof of this, although there was microscopic evidence of a slight interstitial change in the kidney. Again, in rabbit B35, a fresh non-nephritic animal, no bleeding occurred after injection of oxalates, but it did occur on injection of *B. pyocyaneus* + oxalates, causing a rise of the blood urea to 77 mg. per cent.

2. Is an acute nephritis necessary as a predisposing cause, or is a chronic nephritis sufficient without any acute exacerbation? So far as my experiments have gone an acute exacerbation would seem to be essential. In every case in which bleeding occurred in a chronic nephritis an acute or subacute exacerbation has been superimposed upon the chronic.

3. Organisms of the coliform group seem, so far as my experience goes, to be the most potent in causing haemorrhage. *B. pyocyaneus* and *B. coli* can both cause it, but the latter less than the former.

4. Provided a chronic oxalate nephritis has been previously produced, mere introduction of organisms without oxalate is sufficient to cause the necessary acute exacerbation, and to lead to haemorrhage. In rabbit B11 (see Table I) on March 8th the blood urea was 42 mg. per cent. *B. pyocyaneus* was injected alone, and the blood urea rose to 110 mg. per cent.; bleeding occurred on several occasions and macerated foetuses were aborted at term.

Interpretation of the Experimental Results.

I should like to put before you the thesis that external accidental haemorrhage, concealed haemorrhage, retroplacental haematoma, and placental infarction are an essential unity with a common underlying cause. Each is simply the effect of a toxæmia, the toxin being probably the product of organisms, which first of all produce an acute nephritis, this being predisposed to by an already damaged kidney. One of the functions of the healthy kidney is to excrete toxins of endogenous origin—hence the bacilluria that is found in most healthy pregnant women. If the kidney is severely damaged it can no longer fulfil its functions and the endogenous toxin is locked up in the circulation. It may still further damage the kidney, thus setting up a vicious circle. Acting on the endothelium of the vessels, it destroys it here and there and thus produces thrombosis—for example, in the veins of the broad ligament, or in the muscular wall of the uterus, as described by Whitridge Williams² in 1915, or in the kidney or liver. If it acts on the endothelium of a capillary, the endothelium forming the only coat, the capillary wall may be completely destroyed, giving rise to haemorrhage in the fibro-muscular wall of the uterus. The same occurs in the dilated and engorged capillaries of the decidua, and leads to retroplacental haematoma and to external accidental haemorrhage. The syncytium covering the villi may be looked on as a vascular endothelium, with which indeed it is continuous. Like the endothelium it prevents clotting. If it be damaged here and there by the syncytio-lysin thrombosis occurs in the intervillous space, leading to infarct formation; and, as would be expected, the latter may be associated with external haemorrhage or with retroplacental haematoma (Fig. 14), or with both, as in rabbit B30.

The negative experiments of 1923-4-5 seem to prove that the haemorrhage is not caused directly by the organisms or their toxins, for in most of these experiments the animal died one or two days after the organisms were injected, and yet no haemorrhage had occurred. The toxæmia was therefore exceedingly severe—severe enough to cause death of the animal—and yet produced no haemorrhage. I have lately repeated these experiments with *B. pyocyaneus* with estimations of blood urea. The latter has not increased as a result of the injections and no haemorrhage has occurred. It is probably the kidney acutely damaged by the organisms that fails to excrete endogenous toxins. The latter, accumulating in the circulation, give rise to haemorrhage and

infarction. This opinion is based entirely on these negative experiments and may require modification as a result of further work.

ACCIDENTAL HAEMORRHAGE WITHOUT ALBUMINURIA.

It is said that accidental haemorrhage may occur without nephritis. At present I doubt very much whether this is so; and more evidence is necessary of the absence of nephritis in any given case than is commonly adduced. The mere absence of albumin in the urine is not sufficient evidence of the absence of nephritis, for it is known that acute nephritis may exist without any albuminuria, and examination of the urine in acute oxalate nephritis showed that albumin might be entirely absent even when the blood urea had reached a very high figure. In rabbit B30 there was no albumin, though the blood urea had reached 128 mg. per cent. In addition to testing the urine for albumin use must in future be made of all the more modern methods of estimating kidney function, more especially the blood pressure, urea concentration test, and blood urea estimation, and where the kidney is available it must be examined histologically as far as possible throughout. Liver function tests, especially the phenol-tetrachlorophthalein excretion test, should also be carried out, for it is possible that a damaged liver may act in the same way as a damaged kidney.

It is also possible that many cases of so-called accidental haemorrhage may be really examples of low implantation of the placenta, and the greatest care must be taken in future to exclude these cases. A case which I treated about a year ago proves that well marked concealed haemorrhage may occur with placenta praevia, and even this possibility must be kept in mind. At least two other similar cases have been recorded—one by Eardley Holland⁸ and the other by Williamson.⁹

In future work an attempt must be made to ascertain the source and nature of the toxins at work, whether chemical or bacterial, and to trace the connexion which undoubtedly exists between accidental haemorrhage and eclampsia. This will involve a carefully co-ordinated and prolonged clinical and experimental study.

SUMMARY.

1. By setting up a chronic oxalate nephritis and then causing an acute exacerbation of the nephritis by introducing oxalates plus certain organisms it is possible to produce in pregnant rabbits accidental haemorrhage, both external and concealed, and placental infarction. This method is successful in 100 per cent. of cases.
2. Haemorrhage can be produced, though less easily, by setting up an acute oxalate nephritis and then introducing organisms.
3. A similar result can be obtained, also with less certainty, by producing an acute oxalate nephritis without subsequent introduction of organisms.
4. A similar result can be obtained by setting up a chronic nephritis and afterwards introducing organisms. The latter first set up an acute exacerbation, and haemorrhage occurs later. The result in this case is also less certain than by the first method.
5. In every case in which haemorrhage has so far been caused, an acute or subacute exacerbation of the nephritis, as indicated by a rise in the blood urea, has preceded the haemorrhage.
6. The coliform group of organisms seems to be the most potent in producing the acute nephritis that predisposes to haemorrhage and infarction.
7. An acute oxalate nephritis leads to marked retention of urea, but even when the urea concentration in the blood is at its highest point no albumin may be present in the urine. It is important to bear this in mind before excluding nephritis in accidental haemorrhage.
8. These experiments show that nephritis, acute or chronic, is an important predisposing factor in the production of accidental haemorrhage and placental infarction, and that toxæmia is the exciting cause. It is believed that organisms only act by setting up an acute exacerbation of the nephritis, and that they do not lead directly to

the haemorrhage, the latter being caused by endogenous poisons held up in the circulation by the acutely damaged kidney.

All the work in connexion with this research was carried out in the Research Laboratory of the Royal College of Physicians, Edinburgh, and to the Curator, Superintendent, and Laboratory Committee I am much indebted for the facilities placed at my disposal.

An Address

ON

THEORY AND PRACTICE IN RELATION TO THE TREATMENT OF CANCER WITH LEAD.*

BY

W. BLAIR BELL, B.S., M.D.LOND., HON.F.A.C.S.,
PROFESSOR OF GYNAECOLOGY AND OBSTETRICS IN THE UNIVERSITY OF
LIVERPOOL; GYNAECOLOGICAL AND OBSTETRICAL SURGEON, ROYAL
INFIRMARY, LIVERPOOL; HONORARY FELLOW, AMERICAN
GYNAECOLOGICAL SOCIETY; DIRECTOR, LIVERPOOL
CANCER RESEARCH.

(With Special Plac.)

In the investigation of so complex a question as the nature and control of malignant disease it cannot be denied that the conversion of a working hypothesis, with which the investigator must start, into a definite and substantial generalization by the putting together of existing scientific facts and the elucidation of further evidence, is of vastly greater ultimate importance than the initial attempts at control based on the generalization enunciated. By this I mean that, provided a generalization concerning the true nature of malignant neoplasia can be established beyond question, some control of this disease—limited perhaps, as I shall explain later—must assuredly follow, if not at the first attempt, at any rate as the result of subsequent modifications and developments.

It has, therefore, been our chief endeavour to substantiate our hypothesis from every point of view. First let me state what our working hypothesis has been; afterwards I will bring forward evidence as to its correctness—evidence that before long will, we hope, enable us to affirm the generalization beyond criticism.

THEORY.

To us malignant neoplasia appears to be a reversion of the somatic cell to the early embryonic type which forms the trophoblast. We regard the chorionic epithelium as being a normally malignant tissue that comes under somatic control, as we have described in previous communications. It is malignant in that it is dependent on its own efforts to obtain nourishment for itself and, indirectly, for the growing embryo.

We believe that if it be possible for a cell to pass through all the phases of undifferentiation to a differentiated state with increasing specialization, as seen in the human embryo, there should be no difficulty in realizing that a differentiated cell is capable in certain circumstances of retracing the phases back to undifferentiation. This process is known as dedifferentiation, and it has been definitely shown to occur in normal differentiated cells grown *in vitro*.

* This is the full text of the address given by Professor Blair Bell in introducing the discussion on the treatment of cancer by lead at the Medical Society of London on March 22nd. A report of the discussion, including an abstract of Professor Blair Bell's address, was published in our columns on March 27th (p. 568). A report of his reply appeared on page 572.

Pathologists have long spoken of the undifferentiated cells seen in malignant neoplasia; but, strictly speaking, we should speak rather of the dedifferentiated cells. This dedifferentiation we hold to occur as the result of the action of the innumerable causes—mechanical, bacteriological, radiological, thermic, and the rest—all of which lead to a common, precancerous, condition of impaired vitality with starvation—possibly oxygen deficiency—in the cell. Whatever the actual metabolic disturbance produced may be, it is evident that the damaged cell, thrown on its own resources, must either recover, die, or develop abnormally in order to provide itself with nutriment. The last condition can only effectually be ensured if the injured cell revert to a trophoblastic type. This is, I believe, a rational explanation, and is what actually occurs. However, as I have said, such a hypothesis must be founded on accepted facts before it can become a generalization on which we can base our methods of control. We have, therefore, sought and found evidence in support of our hypothesis along the following lines: (a) Morphological. (b) Constitutional—(1) chemical constitution; (2) physico-chemical state. (c) Physiological. (d) Toxicological.

A comparative study on these lines with regard to the similarity of, and differences in, the structure and function of various tissues may be considered reasonably comprehensive. It is, indeed, a study so important and so extensive that some time must elapse before we can obtain an unequivocal and final proof from every point of view. I shall here indicate only our efforts along these lines, and the results obtained.

Morphological Evidence.

The histological evidence of the structure and mode of progression of malignant cells very strongly supports the view that these cells are of a dedifferentiated type, and that this dedifferentiation of the cell is comparable with its degree of malignancy. Moreover, I must call attention to the fact that in malignant neoplasia there is a tendency to syncytial arrangement on the part of the cells. Pathologists must often have noticed how true this is, not only in carcinoma, but also in sarcoma. Figs. 1 and 2 illustrate this phenomenon. In the section of carcinoma (Fig. 1) it will be observed that the syncytial tissue surrounds blood channels preparatory to perforation of them—a process exactly represented in the development of the early placenta (Fig. 3).

Again, while it is evident, as already stated, that in malignant cells developed from somatic tissues there is some degree of development in the tissue concerned, but earlier stage of development in the tissue concerned, but also towards the totally undifferentiated chorionic epithelium, yet there is an exception to this dedifferentiation in the development of malignant neoplasia in the case of chorion-epithelioma, which reproduces normal chorionic epithelium. In short, whereas benign neoplasia is a result of hyperplasia in normal tissues, malignant neoplasia is a process of dedifferentiation except in the case of chorion-epithelioma which represents hyperplasia of a normally malignant tissue—the chorionic epithelium.

Constitutional Evidence.

Chemical Constitution.—Although there are related secondary chemical differences between malignant cells and normal resting tissues, it is the lipin content, especially that of the phosphatides, and the phosphatide-cholesterol ratio that are interesting, for these substances are of primary importance in the constitution of the cell. Professor W. C. McC. Lewis, Dr. J. W. Corran, and Dr. M. Jowett have found that the phosphatide content and the phosphatide-cholesterol ratio are much higher in malignant than in normal tissues and benign tumours, and that these figures reach a maximum in the constitution of the chorionic epithelium (Table I). Further work is being done on this important subject.

Physico-chemical State.—With regard to the physico-chemical state of the cell membrane, it is obvious that permeability is a matter of prime importance; for, if a cell be in urgent need of nutriment, permeability may be a deciding factor in the continuance of vitality, as indeed

TABLE I.

Human Tissues Examined.	Water (per cent.).	Phosphatides (per cent. of dry weight).	Phosphatide-cholesterol Ratio.
Normal tissues ...	75.3 (80.9)	2.1 (1.5)	2.5 % (2.8) "
Innocent neoplasms ...	81.5	4.1	3.9
Malignant neoplasms ...	89.9	6.8	4.7

This table brings the details of our work on this subject up to date. The figures of innocent neoplasms, so far obtained, have been placed in parentheses, for we consider the number of our experiments in this respect too small. There is no doubt, however, that innocent neoplasms will fall into their proper place in this table.

it is an absolute requisite for rapid growth. Now it is interesting that the degree of permeability of the cell membrane is dependent on the phosphatide-cholesterol ratio: a high cholesterol content favours impermeability, whereas a low cholesterol content and a high phosphatide favour permeability, for this ratio is consistent with an oil in water type of emulsion.³

Physiological Evidence.

Many attempts have been made to discover differences between the metabolism of the malignant and that of the normal resting cell; but until recently little of importance had been established. Two years ago, however, Professor Warburg of Berlin commenced to publish a series of most valuable papers on the glycolytic power of various tissues. The chief conclusion derived from his most ingenious experiments is that, whereas in normal resting tissues respiration is high and energy is produced exclusively by oxidation processes, malignant tissues have a lower respiration, and obtain a considerable proportion of their energy by glycolysis. Moreover, Warburg has shown that although a normal resting cell has a slight glycolytic power in the absence of oxygen, in aerobic tissue, however, exerts its perform glycolysis; malignant tissue, however, exerts its glycolytic power even in the presence of oxygen. So definite is Warburg's work on this main line that it is unlikely ever to be upset by subsequent researches; indeed, it has already been fully confirmed by Murphy and Hawkins of the Rockefeller Institute, New York,¹¹ and by others.⁸

Certain other investigations have naturally followed. Warburg has stated that benign tumours lie between malignant and resting tissues in regard to their glycolytic power. It is unfortunate, however, that this investigator should have chosen papilloma of the bladder as a representative of an innocent neoplasm, and there is little doubt that considerable difference would be found in the glycolytic power of this tumour and that of, say, a fibroma. This is a matter that is easily settled, and it in no way affects Warburg's general conclusion.

What has, however, interested us is the question of the position of the chorionic epithelium in respect of this glycolytic ability of this tissue is even greater than that of malignant tissues, but that it does not perform glycolysis aerobically. There is no doubt that his work in regard to the chorion and that of, say, a fibroma. This is a matter that is easily settled, and it in no way affects Warburg's general conclusion.

However, these workers commit themselves to the definite statement that, as regards the placenta, the type of metabolism is exactly the same in respect of glycolysis as that of frankly malignant tissue (Table II). I have little doubt

F. J. BROWNE: ACCIDENTAL HAEMORRHAGE AND PLACENTAL INFARCTION.

FIG. 1.—Experiment of September 18th, 1923. Foetal rabbit with retroplacental haematoma (1), and placenta (2). (Natural size.)

FIG. 2.—Experiment of September 18th, 1923. Kidney section showing acute nephritis. Note the swelling of the epithelium of the tubules and the swollen glomeruli. ($\times 180$.)

FIG. 3.—Kidney of rabbit B12. Shows cloudy swelling in convoluted tubules, swollen and congested glomeruli, and well marked early interstitial change. ($\times 80$.)

FIG. 4.—Same as Fig. 3. ($\times 200$.) The swollen epithelium of the convoluted tubules and the interstitial change are well seen.

FIG. 5.—Kidney of rabbit B9. Shows cloudy swelling of epithelium of convoluted tubes, and swollen and congested glomeruli. Early interstitial change is also present, though less evident than in B12.

FIG. 6.—Same as Fig. 5. ($\times 180$.)

F. J. BROWNE: ACCIDENTAL HAEMORRHAGE AND PLACENTAL INFARCTION.

FIG. 7.—Infarcted rabbit's placenta (B30). The macerated foetal rabbit is shown *in situ*, and with the placenta has been cut transversely. (1) Foetus; (2) haematoma between membranes and uterine wall; (3) uterine wall; (4) infarcted placenta.

FIG. 8.—Another infarcted placenta from rabbit B30. Haemorrhages are seen in the wall of the uterus underneath the placental site. (1) Placenta; (2) thrombi; (3) uterine wall; (4) mesometrium. The macerated foetus has been removed.

FIG. 9.—Another infarcted placenta from rabbit B30. The placental tissue in all these cases, subtending the thrombi, is firm and of liverish consistence.

FIG. 10.—Section of infarcted area from placenta of rabbit B30. The closely packed villi, with dilated, engorged capillaries, are seen. The picture is taken from an area immediately overlying one of the thrombi in Fig. 7. ($\times 75$.)

FIG. 11.—Drawing of infarcted area. Shows villi with dilated and engorged capillaries. At the extreme right is seen the edge of the thrombus which caused the infarction. ($\times 80$.)

FIG. 12.—Haemorrhage and oedema amongst the muscle fibres of the uterine wall (B30). The large cells are decidua cells, which normally are present in large numbers in the uterine muscle of the pregnant rabbit. ($\times 68$.)

FIG. 13.—Haemorrhage in muscle wall of uterus of rabbit B30. The darkly staining areas are extravasated blood, while around are the muscle fibres of the uterus. ($\times 68$.)

FIG. 14.—Human placenta, showing retroplacental haematoma, and placental infarction. The patient from whom this specimen was obtained had also external accidental haemorrhage. This association of infarction and accidental haemorrhage is not infrequent.

FIG. 1.—Section of carcinoma of breast, showing syncytial arrangement of cancer cells. ($\times 480$.)

FIG. 2.—Section of sarcoma of ovary, showing syncytial arrangement of malignant cells. ($\times 550$.)

FIG. 3.—Section of early placenta showing foetal ectoderm surrounding blood spaces. ($\times 400$.)

FIG. 4.—Coagulation necrosis, produced by lead, in the chorionic epithelium of the rabbit. It will be observed that the adjacent maternal tissues (above and below) are unaffected. ($\times 120$.)

FIG. 5.—Coagulation necrosis, produced by lead, in the chorionic epithelium of the rabbit. The maternal tissues below and between the advancing columns of foetal ectoderm are unaffected. ($\times 225$.)

FIG. 6.—Section of post-cricoid carcinoma before treatment. ($\times 170$.)

FIG. 7.—Section of post-cricoid carcinoma shown in Fig. 6 after one massive dose. ($\times 170$.)

FIG. 8.—Section of carcinoma of oesophagus before treatment. ($\times 140$.)

FIG. 9.—Section of cancer of oesophagus shown in Fig. 8 after a single dose of lead, showing almost complete necrosis. ($\times 140$.)

FIG. 10.—Section of gland in case of carcinoma of oesophagus shown in Fig. 8 after a single dose of lead. There is almost complete necrosis. ($\times 140$.)

FIG. 11.—Section of carcinoma of pancreas after considerable treatment, showing fibrosis and atrophy of cancer cells. ($\times 80$.)

FIG. 12.—Section of carcinoma of pancreas shown in Fig. 11 under higher magnification. ($\times 240$.)

† The type of metabolism was similar to that of frank malignant tissue." Murphy and Hawkins (1925).

that when even more careful experimental work is done on the subject this statement will be amply confirmed. Meanwhile, although so far the evidence obtained is confirmatory of our views concerning the essential similarity of the chorionic epithelium and malignant neoplasia, a final decision in regard to the glucolytic power of the different tissues awaits further experimental demonstration. Professor Lewis and his associates are now engaged on this work.

Toxicological Evidence.

Although it goes without saying that the toxicological affinities of a cell must be closely bound up with its chemistry and physical state, we feel that it is necessary, from a practical point of view, that the resemblance in this respect between malignant and chorionic tissues should be made manifest; for, obviously, this is the information on which we have based our methods in the medical treatment of cancer. We have shown,* then, that the chorionic epithelium is singularly sensitive to the action of lead, and that it is possible readily to produce coagulation necrosis of the epithelium of the chorion in the rabbit (Figs. 4 and 5). Lead appears to have the same action on the cells of a malignant neoplasm when it is able to reach them immediately and in sufficient quantity (Figs. 6, 7, 8, 9, and 10). When the effect is gradual fibrosis occurs around the atrophic inactive cancer cells, this being almost a natural form of cure (Figs. 11 and 12). I need hardly again refer to the obvious inference that the biological hormone that arrests the invasive powers of the chorionic epithelium in normal circumstances should also have a similar effect on malignant neoplasia; but we ourselves have, so far, been unable to identify this substance. If our hypothesis be correct, and have reached the stage of generalization, there is plenty of work for others along this line; and, indeed, it is not impossible that other inorganic and organic substances may be found that will exert the same effect as lead.

In concluding these remarks relating to the toxicology of lead I should like to reaffirm my belief in the fact that sufferers with lead poisoning—who if males may be infertile and if women may abort during pregnancy—do not suffer with cancer.† I do not say such a thing is impossible; for obvious reasons it is not; but there appears to be no doubt that carefully corrected statistics do suggest that the two diseases are not compatible.

TREATMENT OF PATIENTS.

Before discussing our work in regard to the treatment of malignant disease I wish to invite your attention to the impossible position that has developed in connexion with the estimation of the value of any form of treatment of this malady in the human subject.

The public and a large body of the medical profession are searching the heavens for what they call a "cure for cancer," and apparently they imagine that some day there will be a means of curing every case of cancer, no matter how advanced the disease may be or what organs may be involved. One moment's consideration should convince anyone familiar with cancer in the human subject of the futility of such an idea.

It goes without saying, of course, that whatever treatment is adopted this is most likely to be effectual when applied early. Nevertheless, many varieties of malignant

disease present so few or such trivial symptoms in their beginnings that they escape recognition by the patient, and it may even be impossible for the doctor to diagnose the condition. I am inclined to think that the difficulties of early recognition will not be completely overcome unless some day a specific reaction which will show the presence or absence of a few cancer cells in the body be discovered—pace the interferometer—and every person from the day of birth to that of death be compelled to undergo examination once a month. Even so, pregnancy will probably vitiate the test.

Meanwhile, although much may be done in the way of education and on preventive lines, such as I have suggested elsewhere,‡ it must definitely be understood that the public will often fail to apply for treatment early, and also that surgery will continue to fail in a large proportion of cases—estimated, I am told, by American authorities to be over 90 per cent.

If we add to these difficulties the situation often created by the involvement of important organs, in which the cure of the disease may mean the death of the patient from other causes, we may indeed express wonder that anyone can expect an infallible cure for all cases of cancer. Yet this attitude of mind appears to be universal in civilized communities, and every attempt to advance the treatment of malignant disease is judged by a false standard, which is based on hope and not on fact.

No method of treatment can be appraised by comparison with an ideal—always impossible of attainment— but rather by properly standardized comparison with other methods of treatment, and it is by this latter method that we wish our own work to be judged. By "standardized comparison" I mean especially that methods of treatment in exactly similar cases and circumstances must be compared. A new method is handicapped from the start: the successful treatment of hopeless cases, in which all other methods have failed, is demanded; and if this result be accomplished the method is not accorded the credit due to it. Still, a method of treatment should be given the chance of starting on the same mark as other methods that are in vogue, including surgery.

Moreover, as I have said, an initial attempt to treat patients by a method based on a generalization must not be too closely regarded as a test of that method. We have looked upon the results obtained so far with critical eyes, and have considered the beneficial effects of lead upon malignant growths as important chiefly because they afford confirmatory evidence of the correctness of our views. It would indeed be ridiculous to expect any method in the treatment of cancer to bridge over the enormous clinical difficulties at the first attempt.

It is, however, fortunate that our application of theory to practice has at one step given fairly satisfactory results; yet there is danger in this. I do not doubt that any preparation of lead may give certain results, and that eventually one preparation will be found to exhibit more definitely than others specific toxic effects in regard to malignant neoplasia, and less towards normal resting tissues. Still, neither I nor the other members of our clinical staff have any doubt concerning the possibility of further modification and improvement in the matter of treatment, for if our generalization is accepted a wide field of research is thrown open.

With regard to the treatment of malignant disease with lead, I have little to add to what has already been published. There are, however, some points I am glad to have the opportunity of emphasizing.

In the first place I would say that there can be little doubt that the use of colloidal lead in the prevention of recurrence after operation is a matter so important that every case subjected to operation for cancer, whether the disease be believed to be totally eradicated or not, should be treated as if the patient still had the disease. Owing to the pressure of work associated with the treatment of existing disease, mostly of a recurrent nature, we ourselves have not had the opportunity of making comparative studies in this matter. Nevertheless, the present is the time when this should be done, for if the method were to be further improved it might be considered unjustifiable for any surgeon to operate without subsequently treating

the patient with whatever preparation might then be in use. I hope, therefore, that some arrangement will be found possible whereby surgeons will be able to treat two series of cases of the same type of disease by operation, administering lead subsequently to every alternate case. Obviously this would not lead to conclusions that could be considered statistically accurate, because the character and malignancy of the cases would vary, and no one man would be likely to have a sufficient number of cases from which to make a true statistical survey. Still, I think any scientific surgeon would be able to come to a more or less satisfactory conclusion in his own mind from such a study.

Secondly, with regard to the treatment of existing disease, it must never be forgotten that the action of lead is probably quantitative, and that satisfactory results naturally depend on the lead reaching the malignant tumour in sufficient quantity without at the same time poisoning the patient. Consequently nothing that can be done to lessen the quantity of lead necessary should be omitted; all large accessible growths should be removed, and in suitable cases x rays may be employed in conjunction with intravenous injections of lead.

I must, too, refer to the extraordinary differences in the susceptibility to the toxic effects of lead observed in patients. It is, however, rare to find a patient with a large growth affected to any considerable extent; it appears that the lead is attracted to the tumour.

It may be thought by some that we have exaggerated the dangers connected with the treatment of cancer with lead. In answer to this we would point out that we have had a considerable experience, and have come to realize that to ensure good results it is absolutely necessary to give the patient as heavy doses and as much lead as can be tolerated.

Results.

I shall say nothing here about the bad effects that may be produced, for, I hope, my colleague Dr. Cunningham will refer to this matter.*

The fact that we have undoubtedly had disasters should be sufficient warning to those who intend to carry out this treatment, possibly with products of unknown toxicity. We hope in due course to be able to establish an organization for those who wish to learn our methods, and to carry out the treatment on proper lines. When, if ever, the history of our endeavours and arrangements comes to be unimpassionately considered, I think it will be found that in no direction could we have acted in any other way than we have done, if we were to protect the public from danger and, at the same time, bring our work to a position of comparative security.

In conclusion I wish to say a few words concerning the general results that we have obtained. I am glad to learn that those best qualified by actual experience of our clinical work to know regard the clinical paper recently published⁷ as being a cautious and moderate statement; for, if we look at our results, as shown in Table III, for the first five

TABLE III.—Fate of Patients: November 9th, 1920, to November 9th, 1925.

	Cases.
1. Admitted, but died before treatment could be commenced	20
2. Died before treatment could be completed... ..	50
3. Died of intercurrent affections	3
4. Died after treatment (including two deaths from acute nephritis, the result of lead poisoning)	106
5. Died as a result of extensive destruction of growth by lead	4
6. Too recent for results to be estimated	14
7. Complete treatment refused, but patients are living normal lives	9
8. Disease completely arrested	10
9. Believed cured, and treatment stopped	31
	227

years, and care to make an estimate of the percentage of successful cases after excluding groups 1, 2, 3, 5, and 6, or after allowing for a proper percentage of the probable failures that would have occurred in these groups, we find there is left an extraordinary percentage of successes in a class of case that has hitherto never been successfully

treated. When we were putting together this paper my collaborators agreed with me that we should make no attempt to work out this percentage, and I will not do so now, for we have never failed to realize the enormous difficulties still to be overcome, and we are exerting our best endeavours to deal with these before we can allow ourselves any peace of mind.

At present we feel there is sure to be great uncertainty and variation in the results that will be obtained by others. For ourselves I think I may truthfully say that we soon forget our successful cases, whereas every failure is a constant source of worry to us. In such circumstances it is not possible for any human being to form a true estimate of his own work, or to share the optimism which onlookers may justifiably have. Had the work been that of others, no doubt we ourselves should have all been extremely impressed with the results obtained; but the heavy responsibility that rests on us for raising a single hope over this age-long problem is sufficient to weigh down any personal satisfaction accruing from our efforts.

To-night, for the first time, I have suggested that the working hypothesis with which I started in the year 1908, or thereabouts, has now practically reached the position of a generalization concerning the true nature of malignant neoplasia, and that, if this be accepted, a real and substantial foundation has been established from which future researches in regard to treatment may proceed. So far we have explored one line only, but with success that has been, I think, beyond expectation.

POSTURE AS A FACTOR IN HEALTH AND DISEASE.

BY

MAUD F. FORRESTER-BROWN, M.D.LOND., M.S.,

WILLIAM GIBSON RESEARCH SCHOLAR; SURGEON TO THE BATH, SOMERSET, AND WILTS CHILDREN'S ORTHOPAEDIC HOSPITAL.

THE subject of the function of the body from the standpoint of mechanics seems to have received from the medical profession in Britain less attention than it deserves. The mechanics of the heart have been the subject of much study, and so have those of the digestive tract; yet it is often forgotten that both the circulatory and alimentary systems can be most seriously interfered with by errors in the locomotory system, more particularly in the bones and muscles which support the body cavities.

This question of bodily mechanics has been made the subject of elaborate study from its anatomical, physiological, and surgical aspects by Dr. Goldthwait of Boston, and he has kindly placed his material at my disposal. I hope that the following sketch of the work already done may stimulate interest in the subject on this side of the Atlantic, and induce practitioners here to continue the study on the material at their disposal.

The examination of recruits during the war showed what a large proportion of the civilized population are using their bodies incorrectly, and the improved physique of men from sedentary occupations after military training showed how readily such errors can be corrected by fresh air, good food, and systematic exercise. Similarly a consideration of the vast proportion of cases of minor ailments which come under the care of the general practitioner will show how large a part faulty mechanics play in their causation, and how important it is that such errors should be treated at their first onset, or, better still, forestalled.

In the production of errors of posture and of bodily mechanics doubtless many factors play their part—such as malnutrition, lack of fresh air, hereditary instability of the nervous system—all of which contribute to depress muscle tone, while this in its turn interferes with the circulation of oxygen and the assimilation of foodstuffs, producing a vicious circle. While it is desirable to break this circle at several points, one of the most practicable and speedy methods is by restoring the mechanics of the skeleton to the normal.

ANATOMICAL CONSIDERATIONS.

It will be asked at once, What are the normal relations of the different parts of the skeleton, for the maintenance of health and the attainment of the maximum mechanical efficiency? This is a question about which there have been differences of opinion.

Drs. Lee and Lloyd Brown studied many hundreds of Harvard University students by means of silhouette photos and found that among these the successful athletes approximated to a type which they have called Class A, and which corresponds to the posture of figures in works of early Greek art, produced when Spartan influence was at its zenith (Fig. 1). Now, it is well known that Sparta paid extraordinary attention to physical fitness, so that this coincidence of types can hardly be due to chance. At the other end of the scale is a type classed by Dr. Goldthwait as D, many of whose members are found to have been subject to chronic ill health; while among hospital patients, the chronic neurasthenics, the visceroptotics, and the pre-tuberculous children nearly all fall into this group, suggesting that it either predisposes to or results from illness (Fig. 2). If the latter, surely it is most necessary that

FIG. 1.—Class A.

FIG. 2.—Class D.

bad mechanical conditions should not be allowed to impoverish still further the vitality of the body. Yet it is rare to find any attention paid by practitioners to this aspect of their cases.

The average individual represents a mean between two extreme types—the slender, loose-jointed individual, represented by the stage contortionist, and the heavy, thick-set John Bull type—but nearly every individual leans obviously to one or other type. The efficient members of each type are found to balance the body in a similar manner, maintaining the upright position with a minimum of muscle effort, while the limbs are ready for movement in any direction with the least possible inertia.

In the efficient posture the vertebrae are kept as vertical as possible, the cervical and lumbar curves, which are of secondary development for the maintenance of the upright position, being flattened as much as possible, so that the muscles in front and behind easily balance one another. Undue increase of these two curves gives a mechanical advantage to the posterior muscles, thus throwing disproportionate strain on the anterior set, most important among which are the muscles of the abdominal wall. Whenever the cervical spine is straightened, the deep fascia of the neck is made tense, and through its attachment to the pericardium, and thereby to the central tendon of the diaphragm, it acts as a suspensory ligament to that muscle and to the heart, enabling both to contract

at better advantage. With a moderate curve in the lumbar region, the body weight is transmitted through the promontory of the sacrum, as it lies in a vertical plane just behind the heads of the femora, and therefore the Y-shaped ligaments of the hip are kept tense, reducing the work of the hip muscles. Thence the weight is transmitted through the front of the knee-joint, keeping the hamstrings tense, and then just in front of the astragalus, making the calf muscle taut. As these include the tibialis posticus and long toe flexors, which are largely responsible for maintaining the arch of the foot, flat-foot is prevented from developing.

THERAPEUTICS.

In view of the important part which good posture plays in preserving the health of the individual, and that which bad posture plays in aggravating or prolonging disease, Dr. Goldthwait recommends certain measures as preventive and curative. The measures on which stress is laid are: Suitable clothing; adequate rest; suitable chairs; a series of simple exercises, with education in correct standing and correct sitting; and external supports for certain severe types of cases.

Suitable Clothing.

Although clothes whose weight is borne from the shoulders are better for the body than those which constrict the waist, yet many modern garments take their bearing from the outer mobile part of the shoulders and induce a hunching of the back and forward projection of the shoulders, in order to prevent them slipping off, which is bad for the posture. They should be cut so that the weight falls on the root of the neck at the back and the inner part of the shoulders.

Anything which constricts the lower ribs and prevents free expansion of the chest is injurious, and it is depressing to find many parents still putting a tight rigid bodice round their girls' chests "in order to give them a good figure." The old-fashioned corset, still in use by the working classes, with its "waist" about the level of the ninth costal cartilage, is equally pernicious, and it is incredible that hard manual work should be possible in such a garment. As soon as the prime of life is past these women begin to haunt the family doctor, complaining of various abdominal symptoms and of general debility.

Rest.

All living cells function by alternations of rest and activity, but it is often forgotten in connexion with muscle training that, while regular exercise is an essential part, exercise as such is not always beneficial; indeed, it may become most injurious, as when applied to an over-stretched, tired muscle—a point frequently neglected in dealing with cases of infantile paralysis.

Because healthy children are benefited by being allowed to play running games, it does not follow that a child with atonic muscles and faulty posture will improve with the same violent exercise, carried to the point of exhaustion in the same faulty attitude. Yet such is largely the principle of physical training carried out in schools. Many people are astonished to find that such a weakly child will get hypertrophy of the muscles and improvement of general nutrition and appetite after lying a large part of each day in the open-air in a correct position, with frequent short spells of exercises designed to give control of the trunk muscles. The same child with ordinary school exercises gets thin and irritable and has a poor appetite. The fact that many growing children are unfit to maintain the upright position continuously for long spells, or for the whole of an adult working day, is not taken into account sufficiently in the organization of schools. To ask them to do so is deliberately to weaken their trunk muscles and initiate the vicious circles previously described. The child of a certain vigour rests these muscles by the varied attitudes of active play; the weakly child, when school is over, slouches in a chair at home and continues the evil process.

It would be beneficial to all children, and is essential for the weaker ones, that they should have several spells each day, more especially after meals, lying on their backs on a hard surface with the spine straight. A small pillow under the lower ribs provides hyperextension of the dorsal

spine and helps weakly children to begin expansion of the chest. This, with the exercises to be described, is quite sufficient treatment for the milder cases of scoliosis, which begin as a postural deformity, easily correctable at first, but soon fixed if a slouch is allowed to persist.

The child who requires remedial exercises for faulty posture will be quite unable to do them correctly while balancing in the upright position, and therefore Dr. Goldthwait lays great stress on the use of *recumbency* for all exercises until a correct use of the trunk muscles has been attained; then the upright balance must be taught. One has only to see a number of children doing the arm movements of the old-fashioned breathing exercise with the spine crooked, the abdomen prominent, and the chin thrust out, their whole attention absorbed by the upper limbs, to realize that it is illogical to exercise the arms until the base of the machine has been put on a stable foundation. Now the upper limbs are the most easily controlled by the brain, while the trunk muscles are the most difficult to co-ordinate; therefore all preliminary exercises should concentrate on the latter. As Dr. Goldthwait points out, the development of force in a particular muscle or muscle group is of little value; what is important is to teach co-ordination; and, again, elaborate co-ordination of the limbs, as in dancing, is of little use if the trunk is still uncontrolled. Whereas, when the trunk is well balanced, all the machinery of the organism—circulation, digestion, etc.—is in good order and the limbs are in the most favourable condition to learn new movements.

Suitable Furniture.

Dr. Goldthwait has pointed out that the attitude of sitting common to weakly children and convalescents—that is, with the spine evenly flexed and the abdomen doubled up—aggravates their weakness by interfering with the organs of digestion and of respiration. Both upright chairs and the ordinary form of lounge-chair, with its simple concave back, conduce to this undesirable attitude. By the simple device of putting a very small cushion opposite the patient's lumbar hollow this can be corrected, and he is able to rest on a slope, of variable inclination, which opens out the lower part of the chest and upper part of the abdomen, while giving complete rest to the spinal muscles (Figs. 3 and 4).

FIG. 3.—Faulty.

FIG. 4.—Correct.

With regard to school children writing and reading at desks: quite as important as the build of the seat and desk is the manner in which the child uses them. In other words, there are no foolproof desks, while even the evils of an unsuitable height can be reduced by correct sitting. The essential is that the spine shall not be flexed, but kept straight, except for its normal curves, while all the forward inclination is obtained by flexion at the hip-joints. This is a restful attitude which can be held for long periods. The best way to train a child to use it first is by making it sit square on its seat, place the hands behind the head, and stretch the body up tall with the chin in and the abdomen retracted; then flex at the hips until the front of the chest nearly touches the desk, when the forearms may be gently lowered on to it.

For cases who are to be kept long recumbent on the back, and for patients on the operating table, whose muscles are relaxed by the anaesthetic, it is most important to place a small cushion under the lumbar hollow, else the back may become unduly stretched; and it is as bad for the sacro-

iliac joints for the lumbar region to be too flat as for it to have a great lordosis.

Corrective Exercises.

Experience has shown the writer that the following half-dozen simple exercises, designed by Dr. Goldthwait, will rapidly develop the chest and promote a good posture, provided that they are carried out conscientiously at least twice a day. The average parent, if told that they must be done as often as the hair is brushed and the face washed, will be duly impressed with the need for regularity, and soon realizes that the spine is as important a factor in producing a good appearance as the head. Of course, the class exists to whom the value of even those elementary toilet procedures is not apparent, and with such it is difficult to make headway.

1. Diaphragmatic Respiration.

Position: Flat on the back on a firm table or couch.

First movement: Place the hands lightly on the sides of the chest and push them apart by expanding the lower ribs.

Second movement: Inspire slowly and deeply, allowing the epigastrium to expand (Fig. 5).

FIG. 5.—Inspiration.

Third movement: Expire slowly and steadily while contracting the abdominal muscles and leaving the ribs stationary, so as to force the diaphragm up into the thorax (Fig. 6).

FIG. 6.—Expiration.

Faults.—These two latter movements of abdominal respiration are apt to be difficult for older children, especially girls; they tend at first to let the lower ribs fall and contract the chest before the diaphragm will have had time to relax upwards; and often they retract the abdomen during inspiration, so preventing its descent. Quite young children acquire the movement readily, especially if they are told to swell slowly like a balloon and shrink slowly like one.

2. Stretching Lateral Abdominal Muscles.

Position: Supine.

First movement: Slowly shrug up one shoulder, keeping the elbow straight and pushing from the arm until a strain is felt on the tissues between the lowest ribs and the iliac crest.

Second stage: Slowly relax, if possible leaving the ribs up, while the shoulder sinks down. This should be done three times with each limb and then three times with both together.

Faults.—There is a tendency to bring the ear down to meet the shoulder, or to bend over sideways, instead of stretching towards the head of the couch; also to project the shoulder forwards.

3. Single Leg Raising to Exercise the Abdominal Muscles.

Position: Supine.

First movement: Bend up one knee and rest the foot of that side flat on the table; this fixes the pelvis and prevents lordosis, which occurs where the abdominal muscles are too weak to antagonize successfully the erector spinae.

Second movement: Slowly raise the opposite leg with the knee straight and tense.

Third movement: Slowly lower the leg to the table again. Repeat three times each side. Never lift both legs at once, as this induces lordosis.

Faults.—Weakly patients are apt to twist sideways and wriggle as they raise the limb.

4. Exercising Lateral Abdominal Muscles.

Position: Supine.

First movement: Slowly draw up "hip"—that is, pelvis—one side towards the shoulder. This throws into action the lateral abdominal muscles, which were stretched by Exercise 2, and which are always weak in these cases, although usually shortened.

Second movement: Slowly relax.

Faults.—Tendency to draw the shoulder down by the scapulo-thoracic muscles, instead of localizing the contraction to the abdominal ones.

5. Back Flattening—Supine.

Position as before.

First movement: Attempt to press lumbar vertebrae against table, by lifting the region of the coccyx forward (by glutei) and contracting the abdominal muscles. The instructor should place a hand under the lumbar hollow and ask the patient to compress it. This reduces lordosis.

Second movement: Relax, so that the lumbar curve is restored by elastic recoil.

Faults.—At first patients usually lift the lumbar spine instead of the coccyx. When they have stretched it correctly they are apt to revert to spasm of the erector spinae, instead of mere recoil by relaxation.

6. Back Flattening against a Wall.

Position: Standing with feet four inches from the wall (nearer makes the exercise too difficult); thighs sloping backward till buttocks rest against the wall; trunk relaxed.

First movement: Slowly uncoil back from below upwards so that the spinous processes rest evenly against the wall.

Second movement: Increase the pressure of the lumbar spine against the wall by contracting the abdominal muscles.

Third movement: When the lumbar and thoracic spines are flat against the wall try to flatten out the cervical spine against it while pushing the occiput upwards on the wall. It is, of course, impossible for a normal individual to touch the wall with the whole spine at once; indeed, the cervical stretching should not be attempted until the lumbar region is mobile. This is an excellent exercise for mobilizing a rigid spine without violence.

When the patient is an adept at the above exercise he should first be taught to stand correctly by getting the back stretched against the wall as in Exercise 6, and then gently raising him forward to the upright position, while he keeps the back flat and the abdomen retracted. These weakly individuals cannot maintain the position long at first, and should not be asked to do so.

The next stage is to walk with the body balanced correctly, and at first it is difficult to teach them not to try to hold up the ribs by hunching up the shoulders, but to push the chest up from below by contraction of the abdominal muscles. The arms must be made to swing freely and loosely from the shoulders.

Finally, some rapid exercise should be given to induce deep respiration, such as skipping, but it is harmful to give this until the fundamentals of balance are acquired correctly, and even then it should be stopped short of fatigue. Indeed, with children, once correct control of the body has been acquired, their spontaneous play will provide enough forms of rapid exercise.

Supports.

For elderly people whose muscles are too atrophied to allow of more than a moderate recovery of tone it may be desirable to order some form of external support. These patients are very likely to show signs of strain in the sacro-iliac and lumbo-sacral joints, often associated with arthritis, but their symptoms are readily relieved by a support which corrects the lordosis and supports the pendulous abdomen.

To achieve this any support must bridge completely across the lumbar hollow—a requirement that is more often forgotten than remembered by belt-makers. In women, if they are not too heavy, a well fitting corset may suffice. Dr. Goldthwait has a useful method of reinforcing the corset in its pull round the pelvic bones by attaching 6-inch webbing to the side seams to form an outer belt, which fastens in front by small straps and buckles. Another useful device of his is to apply inside the back of the corset a leather shield carrying two upright steels of only moderate spring, so that the corset continually pulls the patient back against these, thus reducing the lumbar curve. For men a leather support with similar steels is useful; it should support the lower ribs at the back, but not reach above the umbilicus in front, so that respiration is free. Supports of this type do not interfere with development of the trunk muscles, while they prevent overstrain of the weak muscles when fatigue sets in, for in adults the amount of rest that should be practicable for children is rarely obtainable.

NOTE BY DR. GOLDTHWAIT, Boston, U.S.A.

A paper such as Dr. Forrester-Brown has presented is worthy of much greater consideration than is commonly given to scientific communications, since the principles underlying it are fundamental, dealing with structure or the anatomy, and function or the physiology, the two great basic subjects of medical education. That all persons are not made alike is obvious to all who really observe the human species, and that these variations, because of their varying activities, must be associated with variations in

physiology should hardly require argument. A racehorse must have a different physiology from the Shire or Clydesdale, and the same should be expected of the different types in the human family. The more our patients are studied from this point of view the more easily are the conditions understood.

The way the body is used is naturally important if the world's standards of high efficiency are to be obtained. The drooped relaxed figure is less good from every point of view than the erect alert figure, and with recent studies the practical appreciation of this fact (this was shown most strikingly by the war experience) has found scientific confirmation.

Suggestions such as Dr. Forrester-Brown has made are not only of value from the point of view of general health, but of the greatest value in understanding and controlling the chronic patients as they present themselves for treatment. It is with these that the results of the two features mentioned by Dr. Forrester-Brown—that is, structure and peculiarity of use—are most easily seen, and once such appreciation is had, relief is hopefully to be expected.

After thirty-five years of practice dealing almost wholly with the chronic patient, the belief has become increasingly more certain that, until these features are recognized, the chronic patients will continue to represent the great reproach to our profession that they are to-day.

THE SYMMETRICAL UREA COMPOUNDS AS CHEMOTHERAPEUTIC AGENTS.

BY

J. E. R. McDONAGH, F.R.C.S.,
SURGEON TO THE LONDON LOCK HOSPITAL.

It has been my aim for some years past to find a drug or drugs suitable for use in the acute stage of disease. The first preparations introduced were colloid manganese hydroxide (1917) and manganese butyrate (1920), the latter being still the best preparation in use for furunculosis. But, to combat widespread infections caused by the staphylococcus and other Gram-positive and Gram-negative micro-organisms, it has been necessary to search for compounds capable of conducting more electricity to the host's protective substance (protein particles in the plasma) than can manganese butyrate. I should, perhaps, mention here that, according to my view of morbid processes, disease occurs when the protein particles in the plasma generally, and those constituting the protoplasm of the leucocytes locally, have to part with some of their electrons at the bidding of an invader, be it a micro-organism or a chemical intoxicant. In the search for more efficient conductors two paths lay open: (1) the preparation of an organic compound of manganese possessing a vehicle with a larger nucleus than butyric acid; (2) the preparation of an organic compound made up of an enormous vehicle and depending for the conductor action upon the liberation therefrom of one or more positively charged sodium or hydrogen atoms. Search along the first path proved fruitless, but along the second path fruitful. With the assistance of Dr. F. H. Fairbrother of the British Dyestuffs Corporation, and Dr. J. Thomas of the Scottish Dyes, Ltd., the chemotherapeutic armamentarium has been enriched by four compounds, whose uses form the substance of this article.

Sup. 36.

"Sup. 36" is the symmetrical urea of para-benzoyl-para-amino-benzoyl-1-amino-8-naphthol-3-6-sodium sulphonate.

The action of this compound depends, I believe, upon the liberation of positively charged and conductor functioning

sodium atoms from the 6-positions. The drug can be injected intravenously or intramuscularly in 0.005 to 0.02 gram doses. In the former method the solution must be freshly prepared, but stock solutions will do for the latter, provided the powder has been dissolved in doubly distilled water. Never more than three injections are

In cases of pneumonia, pulmonary thrombosis, and oedema following influenza or prolonged anaesthesia, and occurring in pregnancy, should the patient be in great pain or badly asphyxiated, the action of Sup. 36 should be enhanced by daily subcutaneous injections of oxygen (300 c.cm.). Inhalations of oxygen are of little value, and

CHART 1.—B=Sup. 36 0.01 gram.

CHART 2.—B=Sup. 36 0.01 gram.

required in any one course, and often two or even one suffice. In particularly acute conditions the first two injections should be prescribed on successive days, and the third injection four, five, or six days later.

Sup. 36 is indicated in acute staphylococcal infections, in non-metallic intoxications, and in such conditions as pulmonary thrombosis and oedema, venous thrombosis, and the pernicious vomiting of pregnancy.³ Almost any

the drug is best injected by means of a Bayeux apparatus—a method brought to my notice by Dr. H. L. C. Noel.

Owing to the high mortality of pneumonia and to the fact that no previous chemotherapeutic preparation has proved of value in this infection, I will describe in brief three severe cases which (it seems fair to suppose) owe their life to Sup. 36. In the first case, represented by Chart 3, the patient was delirious at the time the Sup. 36

CHART 3.—B=Sup. 36 0.01 gram.

CHART 4.—B=Sup. 36 0.01 gram. D=Sup. 36 0.01 gram and subcutaneous oxygen 400 c.cm.

sapraemic condition may be combated by Sup. 36. In purulent conditions I have found it abort the lesions if pus has not formed already, and to cause pointing if pus was present beforehand. The moment pus has formed it should be liberated through a tiny incision, and the local application of strong antiseptics and fomentations should be avoided. Oedema, due to the collecting of lymph, may

form around the lesion, and this is apt to cause severe pain and to call for the use of leeches if the lesion is connected with bone—for example, in an acute mastoid, where the timely use of Sup. 36 may render an operation unnecessary. Septic throats, acute and chronic rhinitis, influenza, bronchopneumonia and pneumonia, provided the lesion is not caused by the streptococcus, tend to vanish at once under Sup. 36. In bronchopneumonia the temperature falls to normal one or two days after a single injection, and the objective signs vanish a few days later. Should the temperature rise about one degree at nighttime after the initial fall, the inference may be drawn that there is some hidden focal infection in another part of the body and not necessarily in the lungs. Charts 1 and 2 depict the course of events which have occurred in thirty-nine cases.

CHART 5.—A=Sup. 36 0.01 gram and oxygen 300 c.cm. B=Sup. 36 0.01 gram. C=Oxygen 300 c.cm.

was injected. The patient was under the care of Dr. S. L. McBean.

In the second case, represented by Chart 4, the patient developed a patch in the second lung when the lung first involved was beginning to regress under treatment with Sup. 36. The patch referred to was more of the nature of a reactionary inflammation and subsided at once with a third injection. The patient was under the care of Dr. E. Hogan.

In the third case, represented by Chart 5, the patient did not receive the first injection until the tenth day. The two injections failed to have a dramatic effect, but the patient was old and the heart was beginning to fail. For the next few days the heart was stimulated with digitalis, strychnine, and camphor, and the third injection was made when the heart

was considered to be sufficiently recovered. The day following the third injection the patient registered a distinct improvement, and this was followed by an uneventful recovery. The patient was under the care of Dr. W. H. Harwood-Yarred.

Although this drug appears to be invaluable in the pulmonary complications following prolonged general anaesthesia in elderly people it will not prevent these

if given beforehand. Indeed, if it is injected before the patient leaves the operating table there is a grave risk of pulmonary shock ensuing, owing to the large size of the molecule precipitating the protein particles in the pulmonary capillaries. I have found glycosuria, albuminuria, and acetonuria occurring after an operation vanish under Sup. 36, also similar conditions in pregnancy, provided the protein particles have not been precipitated in the renal or cerebral capillaries. Vomiting in pregnancy is quickly relieved, and acute venous thrombosis and puerperal fever (provided the trouble is not caused by the streptococcus) respond to treatment at once. Acute attacks of asthma may rapidly subside after a single injection, and I have found the drug invaluable in urticaria, angio-neurotic oedema, and in certain mild cases of hay fever. It is indicated in such septic conditions as whitlow, lymphangitis, adenitis, periostitis, and osteomyelitis, and a timely injection may render an operation unnecessary. It has proved of value in clearing up the dermatitis occasioned by organic preparations of sulphur and by such compounds as para-phenylene-diamine (fur dermatitis), and tri-nitro-methyl-nitramine (tetryl), and in intoxications caused by certain amino compounds—guanidine, for example. It may be used also as an antidote in cases of insulin intoxication.

Sup. 36 has been used with great success in canine distemper, foot-and-mouth disease, and equine influenza (the coughing of horses). I have injected couring dogs unable to travel by train because of train-sickness with success.

SUP. 468.

"Sup. 468" is the symmetrical urea of para-benzoyl-para-amino-benzoyl-1-amino-4-6-8-sodium sulphonate.
